The prolongation of the act of circulation implies for the industrial capitalist 1) a personal loss of time, to the extent that it prevents him from performing his own function as a manager of the productive process; 2) a prolonged stay of his product, in the form of money or commodities, in the process of circulation, that is, a process, in which it does not produce any value and by which the direct process of production is interrupted. If this process is not to be interrupted, production must either be restricted, or more money-capital must be advanced, in order that the process of production may proceed on the same scale. This means every time that either a smaller profit is made by the capital hitherto invested, or that additional money-capital must be advanced in order to make the same profit. All this remains unchanged, when the merchant takes the place of the industrial capitalist. Instead of the industrial capitalist, the merchant then spends this prolonged time in the process of circulation; instead of the industrial capitalist, the merchant advances additional capital for the circulation; or, what amounts to the same, instead of a large portion of the industrial capital straying off continually into the process of circulation, the capital of the merchant is wholly tied up in it; and instead of the industrial capitalist making a smaller profit, he must yield a portion of his profit wholly to the merchant. So long as merchant's capital remains within the boundaries, in which it is necessary, the only difference is that this division of the functions of capital reduces the time exclusively needed for the process of circulation, that less additional capital is advanced for this purpose, and that the loss of the total profits represented by the profits of merchant's capital is smaller than it would have been otherwise. If in the above example, a capital of $720\ c + 180\ v + 180\ s$, assisted by a merchant's

capital of 100, leaves a profit of 162, or 18% for the industrial capitalist, or, in other words, implies a deduction of 18, then the additional capital required without the assistance of this independent merchant's capital would probably be 200, and the total advance to be made by the industrial capitalist would be 1,100 instead of 900, which, with a surplus-value of 180, would mean a rate of profit of only $16 \frac{4}{11}\%$.

Now, if the industrial capitalist, who acts as his own merchant, advances not only the additional capital with which he buys new commodities, before his product in process of circulation has been reconverted into money, but also capital (office expenses and wages for commercial laborers) for the realisation of the value of his commodity-capital, or, in other words, for the process of circulation, then these costs form additional capital, but they produce no surplus-value. They must be made good out of the value of the commodities. For a portion of the value of these commodities must once more be converted into these circulation costs; and no additional surplus-value is created thereby. So far as this concerns the total capital of society, it means that a portion of it must be set aside for secondary operations, which are no part of the process of creating value, and that this portion of the social capital must be continually reproduced for this purpose. This reduces the rate of profit for the individual capitalist and for the entire class of industrial capitalists, a result, which follows from every addition of auxiliary capital, whenever such capital is required for the purpose of setting in motion the same mass of variable capital.

To the extent that these additional costs connected with the business of circulating are transferred from the shoulders of the industrial to those of the commercial capitalist, the same reduction in the rate of profit takes place, only to a smaller extent and in another way. The matter now assumes the form that the merchant advances more capital than would be necessary, if these costs did not exist, and that the profit on this additional capital increases the amount of the commercial profit, so that the merchant's capital shares with the industrial capital to a greater extent in the leveling of the average rate of profit, thereby lowering the average profit. If in our above example 50 additional capital are advanced for those costs together with a merchant's capital of 100, then the total surplus-value of 180 is distributed over a productive capital of 900 plus a merchant's capital of 150, a total of 1,050. The average rate of profit then falls to $17 \frac{1}{7}\%$. The industrial capitalist sells his commodities to the merchant at $900 + 154 \frac{2}{7} = 1,054$

2/7, and the merchant sells them at 1,130, namely $1080 + 50$ for costs which he must recover. For the rest it must be assumed that the division between merchant's and industrial capital is accompanied by a centralisation of the expenses of commerce and, consequently, by their reduction.

The question is now: How is it with the commercial wage workers employed by the commercial capitalist, in this case by the merchant?

In one respect, such a commercial laborer is a wage laborer like others. For, in the first place, his labor-power is bought with the variable capital of the merchant, not with the money spent by him as revenue, and consequently this labor-power is not bought for private service, but for the creation of value by means of the capital advanced for it. In the second place, the value of this labor-power, and thus his wages, are determined in the same way as those of other wage workers, namely by the cost of production and reproduction of his specific labor-power, not by the product of his labor.

However, we must make the same distinction between the commercial wage worker and the wage workers directly employed by the industrial capital which we found existing between the industrial capital and merchant's capital, and thus between the industrial capitalist and the commercial capitalist. Since the merchant, as a mere agent of circulation, produces neither value nor surplus-value (for the additional value, which he adds to the commodities by his expenses, resolves itself into an addition of previously existing values, although the question here poses itself: How does he preserve the value of his constant capital?) it follows that the mercantile laborers employed in these same functions cannot very well create any direct surplus-value for him. Here, as in the case of the productive laborers, we assume that wages are determined by the value of labor-power, and that the merchant does not make money by depressing wages, so that he does not allow in his accounts for any advance of wages which he paid only in part, in other words, that he does not make money by cheating his clerks.

The difficulty in the case of the mercantile wage workers is by no means that of explaining the way in which they produce any direct profits for their employer, even though they do not create any direct surplus-value (of which profit is but a changed form.) This part of the question has already been solved by the general analysis of commercial profits. Just as the industrial

capital makes profits by selling labor embodied and realised in commodities for which it has not paid any equivalent, so the merchants' capital makes profits by not paying the productive capital for all the unpaid labor incorporated in the commodities (that is, commodities in so far as the capital invested in their production functions as an aliquot part of the total industrial capital), while in selling it demands payment for this unpaid portion still contained in the commodities and not paid for by itself. The relation of the merchant's capital to the surplus-value is different from that of the industrial capital. The industrial capital produces surplus-value by the direct appropriation of the unpaid labor of others. The merchant's capital, on the other hand, appropriates a portion of this surplus-value by having this portion transferred from the industrial capital to itself.

It is only by its function of realising values that the merchant's capital serves in the process of reproduction as capital and in this capacity gets a share of the surplus-value produced by the total capital. The mass of profits depends for the individual merchant on the mass of capital, which he can invest in this process, and he can use so much more of it in buying and selling, the more unpaid labor his clerks perform. The function itself, by virtue of which the money of the merchant capitalist is capital, is largely performed by his employees. The unpaid labor of his clerks, while it does not create any surplus-value, at least appropriates surplus-value for him, which amounts to the same thing so far as results on his capital go. This unpaid labor is for him, therefore, a source of profit. Otherwise the mercantile business could never be carried on capitalistically, on a large scale.

Just as the unpaid labor of the laborer of the productive capital creates surplus-value for it in a direct way, so the unpaid labor of the commercial wage workers secures a share of this surplus-value for the merchant's capital.

Here is the difficulty: Seeing that the labor time and the labor of the merchant himself do not create any value, but only secure for him a share of already produced surplus-value, how is it with the variable capital, which he invests in the purchase of commercial labor-power? Must this variable capital be included in the expense account of advanced merchant's capital? If not, then it seems to be in contradiction with the law of the compensation of the average rate of profit; for where is there a capitalist who would advance 150, if he could place only 100 in account? If yes, it seems to be in contradiction with the nature of merchant's capital, since this class of

capital does not act in the capacity of capital by setting in motion the labor of others, as the industrial capital does, but rather by performing its own work, that is, the process of buying and selling, and only for this and by this means does it transfer a portion of the surplus-value produced by the industrial capital to itself.

(Therefore the following points must be analysed: the variable capital of the merchant; the law of necessary labor in circulation; the way in which the merchant's labor preserves the value of his constant capital; the role of merchant's capital in the total process of reproduction; and finally, the two-fold materialisation in commodity-capital and money-capital on one side, and in commercial capital and financial capital on the other.)

If every merchant had only as much money as he is personally able to turn over by his own labor, there would be an infinite dissociation of merchant's capital. This dissociation would increase to the extent that productive capital, in the forward march of the capitalist mode of production, would produce and operate on a larger scale. The disproportion between the two classes of capital would increase. In proportion as capital in the sphere of production would be centralised, it would be decentralised in the sphere of circulation. The purely commercial business of the industrial capitalist, and thus his purely commercial expenses, would be infinitely expanded thereby, for he would have dealings with 1,000 capitalists at a time instead of 100. In this way, a large part of the advantage of the independent organisation of merchant's capital would be lost. Not only the purely commercial expenses, but also the other costs of circulation, sorting, expressage, etc., would grow. This applies to the industrial capital. Now let us consider the merchant's capital. In the first place, let us look at the purely commercial labors. It does not require more time to figure with large than with small numbers. But it costs ten times as much time to make 10 purchases at 100 p.st. each as it does to make one purchase at 1,000 p.st. It costs ten times as much correspondence, paper, postage, to carry on a correspondence with 10 small merchants as it does with one large merchant. A limited division of labor in a commercial office, in which one keeps books, another has charge of the treasury, a third carries on the correspondence, one man buys, another sells, another travels, etc., saves immense quantities of labor time, so that the number of workers employed in wholesale commerce stand in no proportion to the comparative size of

the business. This is so, because in commerce much more than in industry the same function, whether performed on a large or a small scale, costs the same labor time. For this reason, concentration appears historically in the merchant's business before it shows itself in the industrial workshop. There are furthermore the expenses for constant capital. 100 small offices cost incomparably more than one large office, 100 small warehouses more than one large one, etc. The costs of transportation, which enter into the accounts of commercial business at least as advances, grow with this dissociation.

The industrial capitalist would have to spend more for labor and circulation in the commercial part of his business. The same merchant's capital, when distributed among many small capitalists would require more laborers for the performance of its functions, on account of this dissociation, and, besides, more merchant's capital would be needed in order to turn over the same commodity-capital.

Let us designate the entire merchant's capital directly invested in the purchase and sale of commodities by B , and the corresponding variable capital invested in wages of commercial help by b . Then $B + b$ is smaller than it would be, if every merchant had to worry along without any assistance and without investing any capital in b . However, we have not yet overcome all difficulties.

The selling price of the commodities must suffice, 1) to pay the average profit on $B + b$. This explains itself by virtue of the fact that $B + b$ represents a reduction of the original B and a smaller merchant's capital than would be required without b . But this selling price must also suffice, 2) to cover not only the additional profit on b , but to recover also the paid wages, the variable capital of the merchant. There is the difficulty. Does b form a new constituent of the price, or is it merely a part of the profit made by means of $B + b$, which takes on the appearance of wages only so far as the mercantile wage worker is concerned, and simply replaces the variable capital from the point of view of the merchant? In this last case, the profit made by the merchant on his advanced capital $B + b$ would be only equal to the profit due to B according to the general rate, plus b , which he pays out in the form of wages without getting a profit on it.

The crux of the matter is, indeed, to find the limits (mathematically speaking) of b . Let us first define the difficulty exactly. Let us designate the capital invested directly in buying and selling commodities by B , the

constant capital (expenses of objective materials of commerce) consumed in this function by K, and the variable capital invested by the merchant by b.

The recovery of B offers no difficulties. It simply represents for the merchant the realised purchase price, the price of production for the manufacturer. The merchant pays this price and in reselling he recovers B as a part of his selling price. Apart from this B, he also receives a profit on B, as we have previously explained. For instance, let the commodities cost 100 p.st. The profit on this may be 10%. In that case the commodities are sold at 110. These commodities cost previously 100, and the merchant's capital of 100 merely makes an additional 10 out of them.

Now let us look at K. It will at most be as large as, but in fact smaller, than that portion of the constant capital, which the producer would have to invest in the department of buying and selling, and which would be an addition to the constant capital invested by him in direct production. However, this portion must be continually recovered by the price of the commodities, or, what amounts to the same, a corresponding portion of the commodities must be continually expended in this form, must, from the point of view of the total capital of society, be continually reproduced in this form. This portion of the advanced constant capital would reduce the rate of profit just as well as the entire mass of it invested in production itself. To the extent that the industrial capitalist gives up the commercial part of his business to the merchant, he is no longer compelled to advance this part of the capital. The merchant advances it in his stead. In a way he does this but nominally, since a merchant neither produces nor reproduces the constant capital consumed by him (the cost of the objective materials of commerce). Its production appears as a specific business, or at least as a part of the business, of some industrial capitalists, who play a similar role as those, who supply the constant capital for the producers of necessities of life. The merchant recovers this constant capital and his profit on it. Both things reduce the profit of the industrial capitalist to that extent. But owing to the economies and concentration which come with a division of labor, he loses less profits than he would, if he had to advance his own capital for this purpose. The reduction of the rate of profit is smaller, because the advanced capital is smaller.

So far, then, the selling price is made up of $B + K + \text{profits on } B + K$. This portion of the selling price offers no further difficulties. But now b, the variable capital advanced by the merchant, enters into this consideration.

The selling price is then made up of $B + K + b + \text{profits on } B + K + \text{profits on } b$.

B makes good merely the purchase price and adds nothing to this price but the profit on B. K adds K itself plus a profit on K; but $K + \text{profit on } K$, the circulation cost advanced in the form of constant capital plus a corresponding average profit, would be larger in the hands of the industrial capitalist than it is in those of the merchant. The reduction of the average profit assumes this form: It is as though the full average profit had been calculated, after deducting $B + K$ from the advanced industrial capital, but the deduction from this average profit for $B + K$ paid to the merchant, so that this deduction appears as the profit of a particular class of capital, of merchant's capital.

But it is different with $b + \text{profits on } b$, or in the present case, where we have assumed a rate of profit of 10%, with $b + (1/10)b$. Here lies the real difficulty.

What the merchant buys with b , is according to our assumption nothing but commercial labor, in other words, labor required for the promotion of the functions of circulating the capital, of performing the acts $C - M$ and $M - C$. But this commercial labor is that labor, which is generally necessary, in order that any capital may perform the functions of commercial capital, the conversion of commodity-capital into money and money into commodities. It is labor which realises values, but does not create any. And only to the extent that a capital performs this function — that a capitalist performs these operations with his capital — does this capital serve as commercial capital and participate in the regulation of the general rate of profit, that is, draw its dividend out of the total profit. But in $b + \text{profit on } b$, it looks as though labor were being paid, in the first place (for it makes no difference, whether the industrial capitalist pays the merchant for his own labor or the clerk employed by the merchant for his), and in the second place, as though it contained a profit on labor, which the merchant himself has to perform. The merchant's capital gets in the first place its b refunded, and in the second place a profit on it. This arises from the fact that it demands pay, in the first place, for work, which it performs in its capacity as merchant's capital, and that it receives, in the second place, a profit in its capacity of capital, for performing work, which is remunerated in the profit as the function of capital. This, then, is the question which we have to solve.

Let us assume that $B = 100$, $b = 10$, and the rate of profit = 10%. We place $K = O$, in order to leave this element of the purchase price, which does not belong here and has already been accounted for, out of consideration. In that case, the selling price would be $B + p + b + p$ (or $B + Bp' + b + bp'$); where p' stands for the rate of profit. This means in figures $100 + 10 + 10 + 1 = 121$.

Now, if b would not be invested by the merchant in wages — since b is paid only for commercial labor, for labor required for the realisation of the value of commodity-capital thrown on the market by industrial capital — then the condition of the matter would be the following: In order to buy or sell anything for $B = 100$, the merchant would spend his time, and we will assume, that this is the only time at his disposal. The commercial labor represented by b , or 10, if paid for by a profit instead of wages, would presuppose another commercial capital of 100, which, at 10%, would be equal to $b = 10$. This second B of 100 would not be added to the price of commodities, but the 10% would. We should then have two operations with 100, making 200, that would buy commodities at $200 + 20 = 220$.

Since merchant's capital is nothing but an independent form of a portion of industrial capital engaged in the process of circulation, all questions referring to it must be solved by representing the problem at first in that form, in which the phenomena peculiar to merchant's capital do not yet appear in an independent shape, but still in direct connection with industrial capital as one of its subdivisions. As an office separate from the workshop, the mercantile capital serves continually in the process of circulation. It is here that we must first analyse the b under consideration — in the office of the industrial capitalist himself.

The office is from the outset always infinitesimally small compared to the industrial workshop. For the rest, it is clear that the commercial operations increase to the extent that the scale of production is enlarged. These are operations, which must be continually performed for the circulation of the industrial capital, in order to sell the product existing in the shape of commodities, to convert the money so received once more into means of production, and to keep account of the whole. The calculation of prices, bookkeeping, managing funds, carrying on the correspondence, all these belong under this head. The more developed the scale of production is, the greater, if not in proportion, will be the commercial operations of industrial capital, and consequently the labor and other costs of circulation

for the realisation of value and surplus-value. This necessitates the employment of commercial wage workers, who form the office staff. The expenses for these, although incurred for wages, differ from the variable capital invested in the purchase of productive labor. It increases the expenses of the industrial capitalist, the mass of capital to be advanced, without increasing the direct surplus-value. For these expenses are made for labor, which is employed only for the realisation of already created values. Like every expense of this kind, these expenses reduce the rate of profit, because the advanced capital increases, but not the surplus-value. If the surplus-value s remains constant, while the advanced capital C increases to $C + \Delta C$, then the place of the rate of profit s/C is taken by the smaller rate of profit $s/(C + \Delta C)$. For this reason, the industrial capitalist endeavors to limit these expenses of circulation to a minimum, just as he does with his expenses for constant capital. Hence industrial capital does not maintain the same relations to its commercial wage laborers that it does to its productive wage laborers. The greater the number of productive wage laborers employed under otherwise equal circumstances, the more voluminous is production, the greater the surplus-value or profit. On the other hand, the larger the scale of production, the greater the quantity of value and surplus-value to be realised, the greater, in other words, the produced commodity-capital, the larger grow the absolute office expenses, even if they do not grow relatively, and give rise to some kind of division of labor. To what extent profit is the first condition for these expenses, is shown among other things by the fact, that with the increase of commercial salaries a part of them is frequently paid by a share in the profits. It is in the nature of things that labor consisting merely of intermediary operations, which are connected either with a calculation of values, or with their realisation, or with the reconversion of the realised money into means of production, a labor whose amount depends on the quantity of produced values about to be realised, should not act as cause of the respective magnitudes and masses of these values, as directly productive labor does, but as their result. The case of the other costs of circulation is similar. In order that plenty may be measured, weighed, wrapped, transported, plenty must be supplied. The amount of labor consumed in packing, transporting, etc., depends on the quantity of the commodities which are the objects of its activity, not vice versa.

The commercial laborer does not produce any surplus-value directly. But the value of his labor is determined by the value of his labor-power, that is, of its costs of production, while the application of this labor-power, its exertion, expression, and consumption, the same as in the case of every other wage laborer, is by no means limited by the value of his labor-power. His wages are therefore not necessarily in proportion to the mass of profits, which he helps the capitalist to realise. What he costs the capitalist and what he makes for him are two different things. He adds to the income of the capitalist, not by creating any direct surplus-value, but by helping him to reduce the costs of the realisation of surplus-value. In so doing, he performs partly unpaid labor. The commercial laborer, in the strict meaning of the term, belongs to the better paid classes of wage workers, he belongs to the class of skilled laborers, which is above the average. However, wages have a tendency to fall, even in proportion to the average labor, with the advance of the capitalist mode of production. This is due to the fact that in the first place, division of labor in the office is introduced; this means that only a onesided development of the laboring capacity is required, and that the cost of this development does not fall entirely on the capitalist, since the ability of the laborer is developed through the exercise of his function and increases so much faster, the more onesidedly the division of labor develops. In the second place, the necessary preparation, such as the learning of commercial details, languages, etc., is more and more rapidly, easily, generally, cheaply reproduced with the progress of science and popular education, to the extent that the capitalist mode of production organises the methods of teaching, etc., in a practical manner. The generalisation of public education makes it possible to recruit this line of laborers from classes that had formerly no access to such education and that were accustomed to a lower scale of living. At the same time this generalisation of education increases the supply and thus competition. With a few exceptions, the labor-power of this line of laborers is therefore depreciated with the progress of capitalist development. Their wages fall, while their ability increases. The capitalist increases the number of these laborers, whenever he has more value and profits to realise. The increase of this labor is always a result, never a cause of the augmentation of surplus-value.

We see, then, that a duplication takes place here. On the one hand, the functions of commodity-capital and money-capital (which later become

merchant's capital) are general forms assumed by industrial capital. On the other hand, particular capitals, and therefore a particular series of capitalists, are exclusively devoted to these functions. And these functions develop into specific spheres of enhancing the value of capital.

The commercial functions and expenses of circulation become independent only in the case of the mercantile capital. That side of industrial capital, which is devoted to the circulation, exists not only in its continuous shape of commodity-capital and money-capital, but also in the office alongside of the workshop. But it assumes an independent existence in the mercantile capital. For this capital, its office is its only workshop. The portion of capital employed in the form of expenses of circulation appears much larger in the business of the large merchant than in that of the industrial capitalist, because the offices connected with every industrial workshop are concentrated in the hands of a few merchants, and so is at the same time that portion of the capital, which would have to be invested for this purpose by the entire class of industrial capitalists. These merchants take care of the circulation and provide for the expenses incidental to its continuation.

For the industrial capital, the expenses of circulation appear as dead expenses, and so they are. For the merchant they appear as a source of his profit, which is proportional to the level of the average rate of profit, whose existence is assumed. The investment to be made by the mercantile capital for these expenses of circulation is, therefore, a productive investment. And for this reason the commercial labor which it buys is likewise immediately productive for it.

CHAPTER XVIII. THE TURN-OVER OF MERCHANT'S CAPITAL. THE PRICES.

THE turn-over of industrial capital is the combination of its time of production and time of circulation. It comprises, therefore, the process of production as a whole. The turn-over of merchant's capital, on the other hand; being in reality nothing but a movement of commodity-capital in an independent form, represents merely the first phase in the metamorphosis of commodities, $C \rightarrow M$, as a movement of some capital returning to itself. $M \rightarrow C$, $C \rightarrow M$, is the turn-over of merchant's capital from the mercantile point of view. The merchant buys, converts his money into commodities, then sells, converts the same commodities back into money. And so forth in continuous repetitions. Within the circulation, the metamorphosis of industrial capital always presents itself in the form of $C' \rightarrow M \rightarrow C''$; the money realised by the sale of the produced commodities C' is used for the purchase of new means of production C'' . This amounts to a practical exchange of C' for C'' , and the same money thus changes hands twice. Its movement acts as an intermediary between two different kinds of commodities C' and C'' . But in the case of the merchant, it is the same commodity, which changes hands twice in the process $M \rightarrow C \rightarrow M'$. It merely promotes the reflux of his money to him.

For instance, if a certain merchant's capital is 100 p.st., and the merchant buys for these 100 p.st. commodities and sells these commodities for 110 p.st., then his capital of 100 p.st. has completed one turn-over, and the number of its turn-overs in one year depends on the number of times which it can repeat this movement $M \rightarrow C \rightarrow M'$.

We leave entirely out of consideration at this point those expenses, which may be concealed in the difference between the purchase price and the selling price, since these expenses do not alter in any way the form, which we are now analysing.

The number of turn-overs of a certain merchant's capital shows evidently some analogy to the repeated cycles of money in its capacity as a mere medium of circulation. Just as the same dollar, which circulates ten times, buys ten times its value in commodities, so the same money-capital of the merchant, when turned over ten times, buys ten times its value in

commodities, or realises a total commodity-capital of ten times its value, for instance a merchant's capital of 100 a value of 1,000. But there is this difference: In the circulation of money as a medium of circulation, it is the same piece of money, which passes through different hands and performs repeatedly the same function, thereby making up for the limited number of the circulating pieces of money by the velocity of its circulation. But in the case of the merchant it is the same money-capital, the same money-value regardless of the pieces of money of which it may be composed, which repeatedly buys and sells the amount of its value, thereby returning repeatedly to the same hands from which it departed as $M + 8\Delta$; M , value plus surplus-value. This is characteristic of its turn-over as a turn-over of capital. It always withdraws more money from circulation than it threw into it. By the way, it is a matter of course that an accelerated turn-over of merchant's capital (in which the function of money as a means of payment likewise predominates whenever the credit system is developed) is accompanied by a more rapid circulation of the same quantity of money.

A repeated turn-over of commercial capital, however, never expresses anything else but a repetition of buying and selling; while a repeated turn-over of industrial capital expresses the periodicity and renovation of the entire process of reproduction (which includes the process of consumption). For the merchant's capital, this appears merely as an outward condition. The industrial capital must continually throw commodities on the market and withdraw others from it, in order that the turn-over of merchant's capital may continue rapidly. If the process of reproduction proceeds slowly in general, then the turn-over of merchant's capital does likewise. Now, it is true that the merchant's capital promotes the turn-over of the productive capital, but only in so far as it shortens the time of circulation of the latter. It has no direct influence on the time of production, which is also one of the limits of the time of turn-over of industrial capital. This is the first barrier for the turn-over of merchant's capital. In the second place, aside from the barrier formed by reproductive consumption, the turn-over of the merchant's capital is ultimately limited by the velocity and volume of individual consumption, since the entire part of commodity-capital which passes into the fund for consumption depends on that.

However, aside from the turn-overs in the world of merchants, in which one merchant always sells the same commodity to another, whereby this sort of circulation may assume the aspect of great prosperity during times of

speculation, the merchant's capital abbreviates in the first place the phase C — M for the productive capital. In the second place, under the modern credit system, it disposes of a large portion of the total capital of society, so that it can repeat its purchases, even before it has definitely sold its previous purchases. And it is immaterial in this case, whether the merchant sells directly to the ultimate consumer, or whether a dozen other merchant's intervene between the first merchant and the ultimate consumer. Owing to the immense elasticity of the process of reproduction, which at any time may be driven beyond all bounds, this process finds no obstacle in production itself, or at best a very elastic one. Aside from the separation of C — M and M — C, which follows from the nature of commodities, a fictitious demand is here created. In spite of its independent status, the movement of merchant's capital is never anything else but the movement of industrial capital within the sphere of circulation. But thanks to its individualisation it moves within certain limits independently of the bounds of the process of reproduction, and thereby drives this process itself beyond its boundaries. The internal dependence and the external independence drive merchant's capital to a point, where the internal connection is violently restored by a crisis.

Hence we note the phenomenon that crises do not show themselves, nor break forth, first in the retail business, which deals with direct consumption, but in the spheres of wholesale business and banking, by which the money-capital of society is placed at the disposal of wholesale business.

The manufacturer may actually sell to the exporter, and the exporter may in his turn sell to his foreign customer, the importer may sell his raw materials to the manufacturer, and the manufacturer his products to the wholesale dealer, etc. But at some particular and unseen point, the goods may lie unsold. On some other occasion, again, the supplies of all producers and middle men may become gradually overstocked. Consumption is then generally at its best either because one industrial capitalist sets a succession of others in motion, or because the laborers employed by them are fully employed and spend more than ordinarily. With the growing income of the capitalists their expenditures increase likewise. Besides, we have seen in volume II, Part III, that a continuous circulation takes place between constant capital and constant capital (even without considering any accelerated accumulation), which is in so far independent of individual consumption, as it never enters into such consumption, but which is

nevertheless definitely limited by it, because the production of constant capital never takes place for its own sake, but solely because more of this capital is needed in those spheres of production whose products pass into individual consumption. However, this may proceed undisturbed for a while, stimulated by prospective demand, and in such lines the business of merchants and industrial capitalists prospers exceedingly. A crisis occurs whenever the returns of those merchants, who sell at long range, or whose supplies have accumulated also on the home market, become so slow and meager, that the banks press for payment, or the notes for the purchased commodities become due before they have been resold. It is then that forced sales take place, sales made in order to be able to meet payments. And then we have the crash, which brings the deceptive prosperity to a speedy end.

But the superficiality and meaninglessness of the turn-over of merchant's capital are still greater, because the turn-over of one and the same merchant's capital may promote simultaneously or successively the turn-overs of several productive capitals.

Now, the turn-over of merchant's capital may not only promote the turn-overs of several industrial capitals, but also the opposite phase of the metamorphosis of commodity-capital. For instance, the merchant buys linen from the manufacturer and sells it to the bleacher. In this case, the turn-over of the same merchant's capital — in fact, the same $C - M$, a realisation on the linen — represents two opposite phases for two different industrial capitals. So far as the merchant sells at all for productive consumption, his $C - M$ always means $M - C$ for some industrial capitalist, and his $M - C$ always $C - M$ for some other industrial capitalist.

If we leave out of consideration, as we do in this chapter, K , the expenses of circulation, in other words, if we leave aside that portion of capital which the merchant advances apart from the money required for the purchase of commodities, it follows that ΔK ; K , the additional profit made on this additional capital, will likewise be left out. This is the strictly logical and mathematically correct mode of analysis, if we wish to study the way in which the profits and turn-over of merchant's capital affect prices.

If the price of production of 1 lb. of sugar is 1 p.st., the merchant can buy 100 lbs. of sugar with 100 p.st. If he buys and sells this quantity in the course of one year, and if the annual rate of average profit is 15% he would add 15 p.st. to 100 p.st., and 3 sh. to the price of production of 1 lb. of

sugar, 1 p.st. That is, he would sell one pound of sugar at 1 p.st. 3 sh. But if the price of production of 1 lb. of sugar should fall to 1 sh., then the merchant could buy 2,000 lbs. of sugar with 100 p.st., and he could sell the sugar at 1 sh. 1 $\frac{4}{5}$ d. per lb. The annual profit on capital invested in the sugar business would still be 15 p.st. on each 100 p.st. Only he has to sell 100 lbs. in the first case, while he must sell 2,000 lbs. in the second place. The high or low level of the price of production would not have anything to do with the rate of profit. But it would have a great deal, or even a decisive deal, to do with that aliquot part of the selling price of each lb. of sugar which resolves itself in mercantile profit; in other words, it would have a great deal to do with the addition to the price which the merchant makes on a certain quantity of commodities, or products. If the price of production of a certain commodity is small, then the amount advanced by the merchant for the purchase of a certain quantity of that commodity is also small, and so is the amount of profit made by him on this quantity of cheap commodities. Or, what amounts to the same, he can buy with a certain amount of capital, for instance with 100, a large quantity of these commodities, and the total profit of 15, which he makes on 100, will be distributed in small fractions over each individual portion of this mass of commodities. The opposite takes place in the opposite case. This depends entirely on the greater or smaller productivity of the industrial capital, with whose products he trades. If we except the cases, in which the merchant is a monopolist and monopolises at the same time the production of certain goods, as did the Dutch East India Company once upon a time, we must say that there is nothing more ridiculous than the current idea that it depends on the merchant whether he wants to sell many commodities at a small profit or few commodities at a large profit on the individual commodities. The two limits of his selling price are: On one hand, the price of production of commodities, over which he has no control; on the other hand, the average rate of profit, over which he has also no control. The only thing which he has to decide is whether he wants to deal in cheap or in dear commodities, and even here the size of his available capital and other circumstances have something to say. Therefore it depends wholly on the degree of development of the capitalist mode of production, not on the good will of the merchant, what course he shall follow in this. A purely commercial company like the old Dutch East India Company, which had a monopoly of production, could imagine that it would be able to continue a method,

adapted at best to the beginnings of capitalist production, under entirely changed conditions.

The following circumstances, among others, help to maintain that popular prejudice, which, like all wrong conceptions of profit, etc., arise out of the views of pure commerce:

Phenomena of competition, which, however, concern merely the distribution of mercantile profit among the individual merchants in their capacity as shareholders in the total merchant's capital; such as the underselling of other merchants by one of them for the purpose of beating his competitors.

2) An economist of the caliber of Professor Roscher of Leipsic may still imagine that a change in the selling prices may be brought about by considerations of "prudence and humanity," instead of being due to a revolution in the mode of production itself.

3) If the prices of production fall on account of an increased productivity of labor, and if consequently the selling prices also fall, then the demand, and with it the market prices, often rise even faster than the supply, so that the selling prices yield more than the average profit.

4) A merchant may reduce his selling price (which amounts after all to no more than a reduction of the current profit which he adds to the price) in order to turn over a large capital more rapidly in his business.

All these things concern only competition between merchants themselves.

We have already shown in volume I, that the high or low level of the prices of commodities determines neither the mass of surplus-value produced by a certain capital nor the rate of surplus-value; it is merely true that, according to the relative quantity of commodities produced by a certain quantity of labor, the price of the individual commodity, and with it the share of surplus-value falling upon this price, is greater or smaller. The prices of every quantity of commodities are determined, so far as they correspond to their values, by the total quantity of labor incorporated in these commodities. If much labor is incorporated in few commodities, then the price of the individual commodities is low and the surplus-value contained in them is small. No matter in what proportion the labor incorporated in a commodity is divided into paid and unpaid labor, and no

matter what portion of its price may represent surplus-value, it has nothing to do with the total quantity of this labor, nor, consequently, with its price. On the other hand, the rate of surplus-value does not depend on the absolute magnitude of the surplus-value contained in the price of the individual commodity, but on its relative magnitude, on its proportion to the wages contained in the same commodity. The rate of surplus-value may therefore be large, while the absolute magnitude of the surplus-value in each individual commodity may be small. This absolute magnitude of the surplus-value in each commodity depends in the first place on the productivity of labor, and only in the second place on its division into paid and unpaid labor.

Moreover, in the case of the commercial selling price, the price of production is a condition determined by external circumstances.

The high prices of commerce in former times were due 1) to the dearness of the prices of production, in other words, to the unproductivity of labor; 2) to the absence of an average rate of profit, which enabled the merchant's capital to absorb a much larger quantity of the surplus-value than would have fallen to its share, had the capitals enjoyed a greater general mobility. The cessation of this condition, in both of its aspects, is due to the development of the capitalist mode of production.

The turn-overs of merchant's capital vary in length, their numbers consequently are greater or smaller, in different lines of commerce. Within the same line of commerce, the turn-over is more or less rapid in different phases of the economic cycle. However, an average number of turn-overs, which is found by experience, takes place.

We have already noted, that the turn-over of merchant's capital differs from that of industrial capital. This follows from the nature of the case; one single phase in the turn-over of industrial capital appears as a complete turn-over of some independently constituted merchant's capital, or of a part of some such merchant's capital. This turn-over has also a different relation to the determination of profit and prices.

In the case of the industrial capital, its turn-over expresses on one hand the periodicity of reproduction, and on it depends the mass of commodities, which may be thrown on the market in a certain period. On the other hand, its time of circulation forms a barrier, which is elastic and exerts more or less of a restraint on the creation of value and surplus-value, because it

exerts a pressure on the volume of the process of production. The turn-over therefore acts as a determining element on the mass of annually produced surplus-value, and thus helps to determine the average rate of profit, but it acts as a negative, not as a positive element. For the merchant's capital, however, the average rate of profit exists as a given magnitude. The merchant's capital does not directly participate in the creation of value or surplus-value, and it participates in the formation of an average rate of profit only to the extent that draws a dividend, in proportion to its size in the total social capital, out of the mass of profit produced by the industrial capital.

The greater the number of turn-overs of a certain industrial capital is under the conditions described in Volume II, Part II, the greater is the mass of profits created by it. Now, the formation of an average rate of profit distributes the total profit among the different capitals, not in proportion to their actual participation in its direct production, but in proportion to the aliquot parts which they constitute in the total capital, that is, in proportion to their magnitudes. But this does not alter the essence of the matter. The greater the number of turnovers of the industrial capital as a whole is, the greater is the mass of profits, the mass of annually produced surplus-value, and therefore the rate of profit, always assuming other circumstances to remain unchanged. It is different with merchant's capital. For it, the rate of profit is a given magnitude, determined on one hand by the mass of profit produced by the industrial capital, on the other hand by the relative magnitude of the total merchant's capital, by its quantitative relation to the sum of capital advanced in the processes of production and circulation. The number of its turn-overs does indeed exert a determining influence on its relation to the total social capital, or on the relative magnitude of the total merchant's capital required for the circulation. For it is evident that the absolute magnitude of the total merchant's capital and the velocity of its turn-over are inversely proportioned to one another. But, all other circumstances remaining the same, the relative magnitude of the merchant's capital, or its aliquot proportion in the total social capital, is determined by its absolute magnitude. If the total social capital is 10,000, and the merchant's capital 1,000, then it is $1/10$ of the total; if the total capital is 1,000, and the merchant's capital 100, it is again $1/10$. To that extent, the absolute magnitude of the merchant's capital may vary, while its relative magnitude in the total social capital remains the same. But in the present

case, we assume that its relative magnitude of $1/10$ of the total social capital is given. This relative magnitude, again, is determined by its turn-over. If it is turned over rapidly, its absolute magnitude will be 1,000 in the first case, and 100 in the second, so that its relative magnitude will be $1/10$. But if it is turned over more slowly, then its absolute magnitude may be 2,000 in the first case, and 200 in the second case. Then its relative magnitude will have increased from $1/10$ to $1/5$ of the total social capital. Circumstances which reduce the average turn-over of merchant's capital, for instance, the development of means of transportation, reduce to that extent the absolute magnitude of merchants' capital and thereby increase the average rate of profit. The opposite takes place, if things are reversed. A developed mode of capitalist production, compared to previous conditions, exerts a twofold influence on merchants' capital. In the first place, the same quantity of commodities is turned over with a smaller mass of actually functioning merchants' capital; for the proportion of the merchants' capital to industrial capital is reduced by the more rapid turn-over of merchants' capital and the greater velocity of the process of reproduction that is its basis. On the other hand, the development of the capitalist mode of production turns all production into a production of commodities, which puts all products into the hands of the agents of circulation. This is so much more notable, as under previous modes of production, which produced things on a small scale, a large portion of the producers sold their goods directly to the consumers or worked for their personal orders, leaving out of consideration that mass of products, which were immediately consumed by the producer himself, and that mass of services, which were performed in natura. While, therefore, under former methods of production, commercial capital represented proportionately a larger share of the commodity-capital which it turned over, it was.

absolutely smaller, because a disproportionately smaller part of the total product was produced in the shape of commodities, passed as commodity-capital into circulation, and fell into the hands of merchants. It was smaller, because the commodity-capital was smaller. But it was proportionately larger, not only because its turn-over was slower, and because it constituted a larger portion of the mass of commodities turned over by it, but also because the price of this mass of commodities, and consequently the merchants' capital to be advanced for it, were greater than under capitalist

production on account of a lower productivity of labor, so that the same value was incorporated in a smaller mass of commodities.

Not alone is a larger mass of commodities produced on the basis of capitalist production (taking account also of the reduced value of these commodities), but the same mass of products, for instance, of corn, also becomes to a greater extent commodity, that is, more and more of the product becomes an object of commerce. As a consequence, not only the mass of the merchants' capital, but of all capital invested in the circulation, increases, such as capital invested in marine shipping, railroading, telegraph business, etc.;

However, there is one point of view, which belongs in the discussion of "competition among capitals," namely: The merchants' capital, which is not serving in any function, or serving only in part, grows with the progress of the capitalist mode of production, with the facility of its investment in retail trade, with the increase of speculation, and with the superfluity of released capital.

But, assuming the relative magnitude of the merchants' capital in proportion to the social capital to be given, the difference of the turn-overs in the various lines of commerce does not affect the magnitude of the total profit falling to the share of the total merchants' capital, nor the general rate of profit. The profit of the merchant is determined, not by the mass of the commodity-capital turned over by him, but by the magnitude of the money-capital advanced by him for the promotion of this turn-over. If the yearly general rate of profit is 15%, and the merchant advances 100 p.st., which he turns over once a year, then he will sell his commodities at 115. If his capital is turned over five times per year, then he will sell a commodity-capital of 100 purchase price five times per year at 103, which will amount in one year to a commodity-capital of 500 sold 515. This constitutes the same annual profit of 15% on his advanced capital of 100 as before. If this were not so, then the merchants' capital would yield a much higher profit in proportion to the number of its turn-overs than the industrial capital, and this would be a contradiction to the law of the average rate of profit.

It follows, then, that the number of turn-overs of merchants' capital in the various lines of commerce affects the mercantile prices of commodities directly. The amount of the mercantile addition to the price, the addition of that aliquot part of the mercantile profit of a given capital which falls upon the price of production of the individual commodities, stands in an inverse

ratio to the number of turn-overs, or the velocity of turn-over, of the merchants' capitals in the various lines of commerce. If a certain merchants' capital is turned over five times per year, it will add to a commodity-capital of its own value but one-fifth of the profit, which another merchants' capital of the same value, which is turned over but once per year, will add to a commodity-capital of the same value.

This modification of selling prices by the average time of turn-over of the capitals in different lines of commerce amounts to this: In proportion to the velocity of turn-over, the same mass of profits, which is determined by the annual rate of average profit for any given magnitude of merchants' capital, independently of the specific commercial character of the operations of this capital, is differently distributed over masses of commodities of the same value. For instance, if the merchants' capital is turned over five times per year, it will add $15/5 = 3\%$ to the price of commodities, and if turned over once per year, it will add 15% to their price.

The same percentage of the commercial profit in different lines of industry, according to the proportions of their times of turn-over, increases the selling prices of commodities by different percentages calculated on their values.

On the other hand, in the case of industrial capital, the time of turn-over does not affect in any way the magnitude of the value of the individual commodities produced during that time, although it does affect the mass of value and surplus-value produced in a given time, because it affects the mass of exploited labor. This is indeed concealed and seems to be otherwise, as soon as one has an eye only to the prices of production. But this is due solely to the fact that, according to the previously analysed laws, the prices of production of the various commodities deviate from their values. As soon as we look upon the process of production in its totality, upon the mass of commodities produced by the entire industrial capital of society, we shall find the general law vindicated.

We see then, that a closer inspection of the influence of the time of turn-over on the formation of the values leads us back, in the case of the industrial capital, to the general law and to the basis of political economy, to-wit, the law that the values of commodities are determined by the labor time contained in them. But the influence of the turn-overs of merchants' capital on the mercantile prices reveals phenomena, which, without a very

lengthy analysis of the connecting links, seem to point to a purely arbitrary fixing of prices. They seem to be fixed purely on the intention that a certain capital should make a definite quantity of profits in one year. Particularly it looks, on account of this influence of the turn-overs, as though the process of circulation determined by itself the prices of commodities, independently, within certain limits, of the process of production. All superficial and false conceptions of the process of reproduction as a whole arise from the point of view of merchants' capital and from the conceptions, which its peculiar movements call forth in the minds of the agents of circulation.

If it is realised — and the reader will have realised it to his great dismay — that the analysis of the actual internal interconnections of the capitalist process of production is a very complicated matter and a very protracted work; if it is a work of science to resolve the visible and external movement into the internal actual movement, then it is understood as a matter of course, that the conceptions formed about the laws of production in the heads of the agents of production and circulation will differ widely from these real laws and will be merely the conscious expression of the apparent movements. The conceptions of a merchant, a stock gambler, a banker, are necessarily quite perverted. Those of the manufacturer are vitiated by the acts of circulation, to which their capital is subject, and by the compensation of the general rate of profit.

Competition likewise plays a completely perverted role in these heads. If the limits of value and surplus-value are given, then it is easy to understand, in what manner the competition of capitals will transform values into prices of production and further into mercantile prices, and surplus-value into average profit. But without these limits, we cannot see any reason at all, why competition should reduce the average rate of profit to such and such a level instead of some other, should make it 15% instead of 1,500%. Competition at best can only reduce the rate of profit to one and the same level. But it does not contain any element, by which this level could be determined.

From the point of view of merchants' capital, the turn-over itself takes on the guise of a determining element of prices. On the other hand, while the velocity of the turn-over of industrial capital, in so far as it enables a certain industrial capital to exploit more or less labor, exerts a determining and limiting influence on the mass of profit and thus on the average rate of

profit, this rate of profit exists as an external fact for the merchants' capital, and the internal connection of this rate with the production of surplus-value is entirely obliterated. If the same industrial capital, under otherwise equal circumstances, particularly with the same organic composition, is turned over four times per year instead of twice, it produces twice as much surplus-value and, consequently, profit. And this becomes palpable, as soon and so long as this capital has the monopoly of that improved mode of production, to which it owes its accelerated turn-over. Vice versa, differences in the times of turn-over in different lines of commerce manifest themselves in such a way that the profit made on the turn-over of some given commodity-capital is in an inverse ratio to the number of turn-overs of the money-capital which turns this commodity-capital over. Small profits and quick returns appears particularly to the shopkeeper as a principle, which he follows on principle.

For the rest, it is a matter of course, that this law of turn-overs of merchants' capital holds good in each line of commerce only for the average of turn-overs made by the entire merchants' capital invested in each particular line, and always without a consideration of any succession of alternating and mutually compensating turn-overs of longer or shorter duration. The capital of A, who deals in the same line as B, may make more or less than the average number of turn-overs. This does not alter the turn-over of the total mass of merchants' capital invested in this line. But this is of decisive moment for the individual merchant or shopkeeper. He makes in this case an extra profit, just as the industrial capitalists make extra profits, if they produce under conditions more favorable than the average. If competition compels him, he can sell cheaper than his competitors without lowering his profit below the average. If the conditions, which would enable him to turn his capital over more rapidly, are themselves for sale, such as a favorable location of the shop, he can pay extra rent for it, that is to say, a portion of his surplus-profit is converted into ground rent.

CHAPTER XIX. FINANCIAL CAPITAL.

THE purely technical movements performed by money in the process of circulation of industrial capital, and, as we may now add, of commercial capital, which assumes a part of the circulation movement of industrial capital as its own peculiar movement, — these movements, if individualised into an independent function of some particular capital that performs nothing but just this service, convert a capital into financial capital. In that case, one portion of the industrial capital, and of commercial capital, persists not only in the form of money, of money capital in general, but as money-capital, which performs only these technical functions. A definite part of the total social capital separates from the rest and individualises itself in the form of money-capital, whose capitalist function consists exclusively in performing the financial operations for the entire class of industrial and commercial capitalists. As in the case of the commercial capital, so in that of financial capital a portion of the industrial capital in process of function in circulation separates from the rest and performs these operations of the process of reproduction for all the other capital. These movements of such money-capital, then, are once more merely movements of an individualised part of industrial capital in the process of reproduction.

Capital appears as the first and last point of this movement only to the extent that capital is newly invested, as happens in accumulation. But for every capital, which is already in process, this first and last point appear merely as points of transit. To the extent that industrial capital, from the moment of its exit from the sphere of production to that of its return to it, passes through the metamorphosis $C' — M — C$, M represents merely the final result of one phase of this metamorphosis and becomes at once the starting point of its supplementing second phase, as we have already seen in the discussion of the simple circulation of commodities. And although the $C — M$ of industrial capital signifies always $M — C — M$ for the commercial capital, nevertheless the actual process for this last named capital, once that it has become engaged, is also $C — M — C$. But the commercial capital passes continually through and simultaneously through the acts $C — M$ and $M — C$, that is to say, there is not only one capital in the stage $C — M$,

while another is in the stage $M — C$, but the same capital buys continually and sells continually at the same time, on account of the continuity of the process of production. It is continually and simultaneously in both stages. While one of its parts is converted into money, to be reconverted later into commodities, another is simultaneously converted into commodities, to be reconverted into money.

Whether the money serves here as a means of circulation or of payment, depends on the form of the exchange of commodities. In both cases, the capitalist has to pay out money continually to many persons, and to receive money continually from many persons. This purely technical labor of paying money and receiving money constitutes an employment by itself, which necessitates the making of balances, the balancing of accounts, so far as money serves as a means of payment. This labor belongs to the expenses of circulation, it does not create any values. It is abbreviated by being organised as a special department of agents, or capitalists, who perform this work for all the rest of the capitalist class.

A definite portion of the capital must be continually available as a hoard, as potential money-capital. It constitutes a reserve of means of purchase, a reserve of means of payment, unemployed capital in the form of money waiting to be put to work. And one portion of the capital continually returns in this form. This requires not only the collecting, paying, and bookkeeping operations, but also the storing of a hoard, which constitutes an operation by itself. This work consists indeed in a continual conversion of a hoard into means of circulation and means of payment, and its restoration to the form of a hoard by means of money secured through sales and due payments. This continuous movement of that part of capital, which exists in the form of money, separated from the function of capital itself, this purely technical function causes its own labors and expenses, which belong to the expenses of circulation.

The division of labor brings it about, that these technical operations, which are conditioned on the functions of capital, should be performed as much as possible for the entire capitalist class by one class of agents, or capitalists, into whose hands it is concentrated as their exclusive function. We have here, as in the case of commercial capital, a division of labor in a twofold sense. It becomes a special business, and because it is performed as a special business for the money-mechanism of the whole class, it is concentrated and performed on a large scale. And then a further division of

labor takes place within this special business, on one hand by a separation into various independent lines, on the other by a segmentation of the work within each office of these special lines. Large offices, many bookkeepers and cashiers, far going division of labor, disbursing of money, receiving of money, balancing of accounts, keeping of current accounts, storing of money, etc., all these things, separated from the acts that necessitate these technical operations, make of the capital advanced for these functions a financial capital.

The various operations, whose individualisation gives rise to special lines of financial business, follow from the different capacities of money itself and from its different functions, through which capital in its money-form must likewise pass.

I have pointed out on a previous occasion, that the money business in general developed originally from an exchange of products between different communes.

The financial business, the trade with money as a commodity, developed first out of international commerce. As soon as different national coins exist, the merchants buying in foreign countries must exchange their national coins into foreign coins, and vice versa, or exchange different coins for uncoined pure silver or gold as international money. This gives rise to the business of money-exchange, which is one of the primitive foundations of modern financial business. Out of it developed the modern banks of exchange, in which silver (or gold) serve as world money — now called bank money or commercial money — as distinguished from current money. The business of money-exchange, so far as it consists merely of notes of payment to travelers from one money-exchanger in one country to another in another country, developed as early as Roman and Grecian times out of the simple money-exchange.

The trade with gold and silver as commodities (raw materials for the making of articles of luxury) forms the primitive basis of bullion trade, or of that trade, which promotes the functions of money as world money. These, functions, as previously explained (Volume I, chapter III, 3c), are twofold: A currency back and forth between the various national spheres of circulation for the purpose of balancing the international payments and for performing the migrations of capital in quest of interest; simultaneously with this movement, there is a movement of precious metals from their

sources of production across the world market and a distribution of their supply over the various national spheres of circulation. In England, the goldsmiths still served as bankers during the greater part of the 17th century. The way in which the balancing of international accounts in the money trade is further developed, is not discussed here, any more than any points referring to the business of dealing in valuable papers, in short, we leave out of consideration all special forms of the credit system, since this does not yet concern us here.

In the shape of world money, national money strips off its local character; one national money is expressed in another, and thus all of them are finally reduced to their contents in gold or silver, while these two metals, being the two commodities circulating as world money, are simultaneously reduced to their mutual ratios, which change continually. The money trader makes this intermediate business his special occupation. Money changing and bullion trading are thus the primitive forms of the money trade, and they arise from the twofold functions of money as national money and world money.

The capitalist process of production, and commerce in general, even under precapitalist methods, imply:

The accumulation of money in the shape of a hoard, that is, in the present case, the accumulation of that part of capital, which must always be on hand in the form of money, as a reserve fund of means of payment and means of purchase. This is the first form of a hoard, such as it reappears under the capitalist mode of production, and as it forms in general with the development of merchants' capital, at least for the purposes of this capital. These remarks apply to national as well as international circulation. This hoard is in continuous flux, pours ceaselessly into circulation, and returns uninterruptedly from it. The second form of a hoard is now that of fallow, unemployed, capital in the form of money, including newly accumulated and not yet invested money-capital. The functions first required by this formation of a hoard are those of safekeeping, bookkeeping, etc.

2) This is connected by an expenditure of money in buying, its reception on selling, making and receiving of payments, balancing of payments, etc. The money dealer performs all these services at first as a simple cashier of the merchants and industrial capitalists.

Dealing in money is fully developed, even in its first stages, as soon as its ordinary functions of lending and borrowing are supplemented by the credit business. Of this more in the following part, which deals with interest-bearing capital.

The bullion trade itself, the transfer of gold or silver from one country to another, is merely the result of the trade in commodities. It is determined by the quotations of bills of exchange, which express the stand of the international payments and of the rate of interest on the different markets. The bullion trader as such acts but as an intermediary between results.

In discussing the way, in which the movements and forms of money develop out of the simple circulation of commodities, we have seen (Vol. I, chap. III), that the movements of the mass of money circulating as a means of purchase and payment are determined by the metamorphosis of commodities, by the volume and velocity of this metamorphosis. And we know now, that this metamorphosis is itself but a phase in the entire process of reproduction. As for the movement of the raw materials of money — gold and silver — from their places of production, it resolves itself in a direct exchange of commodities, an exchange of gold and silver as commodities for other commodities. Hence it is as much a phase of the exchange of commodities as the securing of iron or other metals by means of exchange. And so far as the movements of precious metals on the world-market are concerned (we leave aside at this point the consideration of their movements to the extent that they express the transfer of capital by loans, a transfer, which takes place also in the shape of commodity-capital), they are quite as much determined by the international exchange of commodities as the movements of money as a national means of purchase and payment are determined by the exchange of commodities on the home market. The emigrations and immigrations of precious metals from one national sphere to another, which are caused by a depreciation of national coins, or by a double standard, are extraneous to the circulation of money as such and represent merely corrections of deviations brought about arbitrarily by state decrees. And finally, as concerns the formation of hoards, which constitute reserve funds for means of purchase and payment, either for the home trade or for foreign trade, and likewise of hoards, which represent merely a form of capital temporarily unemployed, they are both necessary precipitates of the process of circulation.

Just as the entire circulation of money, in its volume, its forms, and movements, is purely a result of the circulation of commodities which in its turn represents from the capitalist point of view only the process of circulation of capital (including the exchange of capital for revenue, and of revenue for revenue, so far as the expenditure of revenue is realised in retail trade), so it is a matter of course, that the trade in money does not promote merely the circulation of money, a mere result and phenomenon of the circulation of commodities. This circulation of money itself, as a phase in the circulation of commodities, is a fundamental requisite for the trade in money. This trade promotes merely the technical operations of money-circulation, concentrating, abbreviating, simplifying them. The trade in money does not form the hoards, but supplies the technical means by which the formation of hoards may be reduced to its economical minimum (so far as it is voluntary, that is, so far as it is not an expression of unemployed capital or of disturbances of the process of reproduction). For if the reserve funds of means of purchase and payment are managed for the capitalist class as a whole, they need not be so large as they would have to be, did each capitalist manage his own. The trade in money does not buy the precious metals, but merely promotes their distribution, as soon as the trade in commodities has bought them. The trade in money facilitates the squaring of balances, so far as money serves as a means of payment, and reduces by the artificial mechanism of these compensations the amount of money required for this purpose. But it determines neither the connections, nor the volume, of the mutual payments. For instance, the bills of exchange and checks, which are exchanged for one another in banks and clearing houses, reflect quite independent transactions and are the results of real operations. It is merely a question of a better technical compensation of these results. So far as money serves as a means of purchase, the volume and number of purchases and sales are quite independent of the money trade. This trade cannot do anything but abbreviate the technical operations that go with buying and selling, and by this means it is enabled to reduce the amount of cash money required to turn the commodities over.

The money trade in its pure form, which we consider here, that is, the money trade not complicated by the credit system, is concerned only with the technique of a certain phase of the circulation of commodities, namely with the circulation of money and the different functions of money following from its circulation.

This distinguishes the money trade essentially from the trade in commodities, which promotes the metamorphosis of commodities and their exchange, or which gives even to this process the aspect of a process of a certain capital separated from the industrial capital. While, therefore, the commercial capital has its own form of circulation, $M - C - M$, in which the commodity changes hands twice and thereby recovers the money, in distinction from $C - M - C$, in which the money changes hands twice and thereby promotes the exchange of commodities, there is no such special form of circulation, which can be demonstrated in the case of financial capital.

To the extent that money-capital is advanced by a separate class of capitalists for the technical promotion of the circulation of money — a capital representing on a reduced scale the additional capital, which the merchants and industrial capitalists must otherwise advance themselves for these purposes — the general form of capital, $M - M'$, is found also here. By the advance of M , the advancing capitalist secures $M + \Delta M$. But the promotion of the transaction $M - M'$ does not concern itself in this case with the objective materials, but only with the technical processes of this metamorphosis.

It is evident, that the mass of money-capital, with which the money dealers have to operate, is the money-capital of the merchants and industrial capitalists in process of circulation, and that the operations of the money dealers are merely those originally performed by the merchants and industrial capitalist.

It is equally evident, that the profit of the money dealers is nothing but a deduction from the surplus-value, since they are operating merely with already realised values (even when they have been realised in the form of creditors' claims).

As in the trade with commodities, so in that with money a duplication of functions takes place. For a portion of the technical operations connected with the circulation of money must be carried out by the dealers and producers of commodities themselves.

CHAPTER XX. HISTORICAL DATA CONCERNING MERCHANTS' CAPITAL.

THE particular form, in which the commercial capital and financial capital accumulate money, will be discussed in the next part of this volume.

From what has gone before it follows as a matter of course that nothing can be more absurd than to consider merchants' capital, whether in the shape of commercial or of financial capital, as some particular kind of industrial capital, such as that invested in mining, agriculture, stock raising, manufacture, transportation, etc., which constitute side lines of industrial capital formed by division of social labor and thus different spheres for its investment. The simple observation, that every industrial capital, when in the circulation phase of its process of reproduction, performs in the shape of commodity-capital and money-capital the very same functions, which appear as exclusive functions of the two forms of merchants' capital, should make such a crude conception impossible. On the other hand, in commercial and financial capital the differences between the productive nature of industrial capital and its functions in the sphere of circulation are independently individualised, by transferring definite forms and functions assumed momentarily by industrial capital into independent forms and functions of separate portions of capital permanently tied up in circulation. A changed form of industrial capital is widely different from distinctions between productive capitals following from the nature of the various lines of industry.

Aside from the brutality with which the economist ordinarily handles distinctions of form, in which he is interested only so far as their material side is concerned, the vulgar economist is influenced by two other reasons in his violation of distinctions. There is, in the first place, his incapability to explain the peculiar nature of mercantile profit. In the second place, he writes for the apologetic purpose of proclaiming his opinion, that the process of production by its very nature, is the source of such forms as commodity-capital and money-capital, or later of merchants' capital and financial capital, instead of showing that they are due to the specific form of capitalist production, which is conditioned above all on the circulation of commodities and therefore of money.

If commercial capital and financial capital do not differ from the production of grain any more than this differs from stock raising and manufacture, then it is evident that production and capitalist production are one and the same thing, and that especially the distribution of the social products among the members of society for the purpose of productive or individual consumption need no more be promoted by merchants and bankers than the consumption of meat by stock raising or that of clothes by their manufacture.

The great economists, such as Smith, Ricardo, etc., are embarrassed over mercantile capital as a special kind, since they analyse the basic form of capital, industrial capital, and take notice of capital of circulation (commodity-capital and money-capital) only to the extent that it is a phase in the process of reproduction of all capital. The rules concerning the formation of value, profit, etc., which are directly deduced from an analysis of industrial capital, do not fit merchants' capital directly. Therefore these economists leave merchants' capital entirely out of consideration and mention it only as a kind of industrial capital. Whenever they treat of it particularly, as Ricardo does in dealing with foreign commerce, they seek to demonstrate that it does not create any value (and consequently no surplus-value). But whatever is true of foreign commerce, applies also to home commerce.

Hitherto we have considered merchants' capital merely from the point of view of the capitalist mode of production, and within its limits. However, not only commerce, but also merchants' capital, is older than the capitalist mode of production. In fact, it represents historically the oldest free existence of capital.

As we have already seen that the money trade and the capital advanced for it require nothing for their existence but the presence of commerce on a large scale, and further of commercial capital, it is only the latter, which we have to consider here.

Since commercial capital is tied up in the circulation, and since its function consists exclusively in promoting the exchange of commodities, it follows that it requires no other condition for its existence — aside from undeveloped forms arising from direct barter — but those indispensable for the simple circulation of money and commodities. Or rather, the circulation of money is the condition of its existence. No matter what may be the basis

on which production is carried on, which throws its products into circulation as commodities — whether it be the basis of a primitive commune, or of slave production, or of small agricultural, small bourgeois, or capitalist — the character of the products as commodities is not altered, and as commodities they have to pass through the process of exchange and through the forms incidental to it. The extremes, between which merchants' capital acts as a mediator, exist for it as given propositions, just as they do for money and its movements. The only requisite is that these extremes should be present as commodities, regardless of whether production is wholly a production of commodities, or whether only the surplus of the independent producers over the immediate needs satisfied by their production is thrown on the market. The merchants' capital promotes only the movements of these extremes, these commodities, which are premises of its own existence.

The extent to which production ministers to commerce and supplies the merchants, depends on the mode of production. It reaches its maximum under a fully developed capitalist production, in which the product is primarily produced as a commodity, not for direct subsistence. On the other hand, on the basis of every mode of production, commerce promotes the production of surplus products destined for exchange, for the purpose of increasing the enjoyments of wealth of the producers (who are here understood to be the owners of the products). Commerce impregnates production more and more with the character of a production for exchange.

The metamorphosis of commodities, their movements, consist, 1) materially, of an exchange of different commodities for one another; 2) formally, of a conversion of commodities into money by sale, and a conversion of money into commodities by purchase. And the functions of merchants' capital resolve themselves into these functions of buying and selling commodities. It promotes merely the exchange of commodities, which must be conceived at the outset as being something more than a bare exchange of commodities between direct producers. Under slavery, feudalism, vassalage, so far as primitive organisations are concerned, it is the slave holder, the feudal lord, the tribute collecting state, who are the owners and sellers of the products. The merchant buys and sells for many. In his hands are concentrated purchases and sales, and purchase and sale cease consequently to be dependent on a direct necessity of the buyer (as a merchant).

But whatever may be the social organisation of the spheres of production, whose exchange of commodities the merchant promotes, his wealth exists always in the form of money and his money always serves as capital. Its form is always $M - C - M'$. Money, the independent form of exchange value, is his starting point, expansion of the exchange value his independent purpose. He occupies himself with the exchange of commodities and the operations incidental to it, which are separated from production and performed by a non-producer, and this is merely a means to increase wealth and at that wealth in its most general social form, exchange value. His compelling motive and compelling end are the conversion of M into $M + \Delta M$. The transactions $M - C$ and $C - M$, which promote the act $M - M'$, appear merely as stages of transition in this conversion of M into $M + \Delta M$. This $M - C - M'$ is the characteristic movement of merchants' capital which distinguishes it from $C - M - C$, the exchange of commodities between the producers themselves, which has for its ultimate end the exchange of use-values.

To the extent that production is undeveloped, the money wealth will be concentrated in the hands of merchants, will appear in the specific form of merchants' wealth.

Within the capitalist mode of production — that is, as soon as capital has seized hold of production and given to it a wholly changed and specific form — merchants' capital appears merely as a capital with a specific function. But in all previous modes of production, and so much the more production ministers to the direct wants of the producers themselves, merchants' capital appears as the capital which performs the function of capital.

There is, then, no difficulty in understanding how it is that that merchants' capital is the historical form of capital long before capital has subjected production to its control. Its existence and development to a certain level are themselves historical premises for the development of capitalist production. For they are, 1), premises for the concentration of moneyed wealth, and 2), the capitalist mode of production is conditioned on production for exchange, commerce on a large scale instead of with a few individual customers, and this requires also a merchant, who does not buy for the satisfaction of his own individual wants, but concentrates the transactions of many buyers in one commercial transaction. On the other hand, all development of merchants' capital tends to give to production

more and more the character of a production for exchange and to impregnate the products more and more with the character of commodities. But the development of merchants' capital by itself is incapable of bringing about and explaining the transition from one mode of production to another, as we shall presently see.

Within capitalist production, the merchants' capital is reduced from its former independent existence to a special phase in the investment of capital in general, and the compensation of profits reduces its rate of profits to the general average. Then it serves only as an agent of productive capital. The particular social conditions, which formed together with the development of merchants' capital, are then no longer paramount. On the contrary, where merchants' capital still predominates, we find backward conditions. This is true even of one and the same country, in which, for instance, the pure merchants' towns form far better analogies with past conditions than the manufacturing towns.

An independent and prevailing development of capital in the shape of merchants' capital signifies that production is not subject to capital, in other words, it means that capital develops on the basis of a mode of production independent and outside of it. The independent development of merchants' capital stands therefore in an inverse ratio to the general economic development of society.

The independent mercantile wealth, as a prevailing form of capital represents the independent establishment of the process of circulation as against its extremes, and these extremes are the exchanging producers themselves. These extremes remain independent of the process of circulation, just as this circulation remains independent of them. The product becomes a commodity in this case by way of commerce. It is commerce which, under such conditions, develops products into commodities; it is not the produced commodity itself which, by its movements, gives rise to commerce. Capital in the capacity of capital appears here first in the process of circulation. In the process of circulation money first develops into capital. In the circulation, the products first assume the character of exchange values, of commodities and money. Capital can and must form in the process of circulation, before it learns to control the extremes, that is, the various spheres of production between which circulation intervenes as a mediator. The circulation of money and commodities may act as an intermediary between spheres of production of

widely different organisation, whose internal structure is still, predominantly adjusted to the production of use-values. This independent status of the process of circulation, by which various spheres of production are connected by means of a third link, expresses two facts. On the one hand it shows that the circulation has not yet seized hold of production, but as yet regards it as an existing fact. On the other hand, it shows that the process of production has not yet absorbed circulation and made a phase of production of it. But in capitalist production, both of these things are accomplished. The process of production rests wholly upon the circulation, and the circulation is a mere phase of transition of production, in which the product, having been created as a commodity, is realised in money and its elements of production replaced by products, which have likewise been created in the shape of commodities. That form of capital, which developed directly in circulation, the merchants' capital, appears here merely as one of the forms of capital in its process of reproduction.

The rule, that the independent development of merchants' capital is inversely proportioned to the degree of development of capitalist production, becomes particularly manifest in the history of the carrying trade, for instance, among the Venetians, Genoese, Dutch, etc., where the principal gains were not made by the exportation of the products of the home industries, but by the promotion of the exchange of products of commercially and otherwise economically undeveloped societies and by the exploitation of both spheres of production.

Here the merchants' capital is pure, separated from the extremes, the spheres of production, between which it intervenes. This is one of the main sources of its formation. But this monopoly of the carrying trade disintegrates, and with it this trade itself, in proportion as the economic development of peoples advances, whom it exploits at each end of its course, and whose backward development formed the basis of this trade. In the carrying trade, this appears not only as the disintegration of a special line of commerce, but also as the disintegration of the supremacy of purely commercial nations and of their commercial wealth in general, which rested upon this carrying trade. This is but one of the special forms, which expresses the subordination of the commercial capital to the industrial capital with the advance of capitalist production. The manner in which merchants' capital behaves wherever it rules over production is drastically illustrated, not only by the colonial economy (the colonial system) in

general, but particularly by the methods of the old Dutch East India Company.

Since the movement of merchants' capital is $M — C — M'$, the profit of the merchant is made, in the first place, only within the process of circulation, by the two transactions of buying and selling; and in the second place, it is realised in the last transactions, the sale. It is a profit upon alienation. At first sight, a pure and independent commercial profit seems impossible, so long as products are sold at their value. To buy cheap in order to sell dear is the rule of trade. It is not supposed to be an exchange of equivalents. The conception of value is included in it only to the extent that the individual commodities all have a value and are to that extent money. In quality, they are all expressions of social labor. But they are not values of equal magnitude. The quantitative ratio, in which products are exchanged, is at first quite arbitrary. They assume the form of commodities inasmuch as they are exchangeable, that is, inasmuch as they may be expressed in terms of the same third thing. The continued exchange and the more regular reproduction for exchange reduces this arbitrariness more and more. But this applies not at once to the producer and consumer, but only to the mediator between them, the merchant, who compares the money-prices and pockets their difference. By his own movements he establishes the equivalence of commodities.

The merchants' capital is at first merely the intervening movement between extremes not controlled by it and between premises not created by it.

Just as from the mere form of the circulation of commodities, $C — M — C$, money rises not only as a measure of value and medium of circulation, but also as the absolute form of the commodity and thus of wealth, in the form of a hoard, so that its conservation and accumulation as money become its life's purpose, so money, in the shape of a hoard, issues from the mere form of the circulation of merchants' capital, $M — C — M'$, as something which is preserved and increased only by its alienation.

The trading nations of the ancients existed like the gods of Epicure in the intermediate worlds of the universe, or rather like the Jews in the pores of Polish society. The trade of the first independent and highly developed merchant towns and trading nations rested as a pure carrying trade upon the barbarism of the producing nations between whom they intervened.

In the precapitalist stages of society, commerce rules industry. The reverse is true of modern society. Of course, commerce will have more or less of a reaction on the societies, between which it is carried on. It will subject production more and more to exchange value, by making enjoyments and subsistence more dependent on the sale than on the immediate use of the products. Thereby it dissolves all old conditions. It increases the circulation of money. It seizes no longer merely upon the surplus of production, but corrodes production itself more and more, making entire lines of production dependent upon it. However, this dissolving effect depends to a large degree on the nature of the producing society.

So long as merchants' capital promotes the exchange of products between undeveloped societies, commercial profit does not only assume the shape of outbargaining and cheating, but also arises largely from these methods. Leaving aside the fact that it exploits the difference in the prices of production of the various countries (and in this respect it tends to level and fix the values of commodities), those modes of production bring it about that merchants' capital appropriates to itself the overwhelming portion of the surplus-product, either in its capacity as a mediator between societies, which are as yet largely engaged in the production of use-values and for whose economic organisation the sale of that portion of its product which is transferred to the circulation, or any sale of products at their value, is of minor importance; or, because under those former modes of production, the principal owners of the surplus-product, with whom the merchant has to deal, are the slave holder, the feudal landlord, the state (for instance, the oriental despot), and they represent the wealth and luxury, which the merchant tries to trap, as Adam Smith correctly scented in that passage on feudal times, which I have quoted above. Merchants' capital in its supremacy everywhere stands for a system of robbery, and its development, among the trading nations of old and new times, is always connected with plundering, piracy, snatching of slaves, conquest of colonies. See Carthage, Rome, and later Venetians, Portuguese, Dutch, etc.

The development of commerce and merchants' capital brings forth everywhere the tendency toward production of exchange values, increases its volume, multiplies and monopolises it, develops money into world money. Commerce therefore has everywhere more or less of a dissolving influence on the producing organisations, which it finds at hand and whose

different forms are mainly carried on with a view to immediate use. To what extent it brings about a dissolution of the old mode of production, depends on its solidity and internal articulation. And to what this process of dissolution will lead, in other words, what new mode of production will take the place of the old, does not depend on commerce, but on the character of the old mode of production itself. In the antique world the effect of commerce and the development of merchants' capital always result in slave economy; or, according to what the point of departure may be, the result may simply turn out to be the transformation of a patriarchal slave system devoted to the production of direct means of subsistence into a similar system devoted to the production of surplus-value. However, in the modern world, it results in the capitalist mode of production. From these facts it follows, that these results were conditioned on quite other circumstances than the mere influence of the development of merchants' capital.

It follows from the nature of the case that as soon as town industry as such separates from agricultural industry, its products are from the outset commodities and require for their sale the intervention of commerce. The leaning of commerce upon the development of the towns, and, on the other hand, the dependence of the towns upon commerce, are to that extent intelligible. However, in what measure industrial development will keep step with this development, depends upon quite other circumstances. Already ancient Rome, in its later republican days, developed merchants' capital more highly than it had ever existed in the antique world, without any progress in the development of crafts, while in Corinth and in other Grecian towns of Europe and Asia Minor the development of commerce was accompanied by highly developed crafts. On the other hand, in direct opposition to the development of towns and its conditions, the trading spirit and the development of commerce are frequently found among unsettled nomadic peoples.

There is no doubt — and it is precisely this fact which has led to many wrong conceptions — that in the 16th and 17th centuries the great revolutions, which took place in commerce with the through geographical discoveries and rapidly increased the development of merchants' capital, form one of the principal elements in the transition from feudal to capitalist production. The sudden expansion of the world market, the multiplication of the circulating commodities, the zeal displayed among the European

nations in the race after the products of Asia and the treasures of America, the colonial system, materially contributed toward the destruction of the feudal barriers of production. However, the modern mode of production, in its first, period, the manufacturing period, developed only in places, where the conditions for it had been previously developed during medieval times. Compare, for instance, Holland with Portugal. And, on the other hand, when in the 16th, and partially still in the 17th, century the sudden expansion of commerce and the creation of a new world market exerted an overwhelming influence on the overthrow of the old mode of production and the rise of the capitalistic one, this was accomplished on the basis of the already created capitalist mode of production. The world market forms itself the basis of this mode of production. On the other hand, the immanent necessity of this production to produce on an ever enlarged scale tends to extend the world market continually, so that it is not commerce in this case which revolutionises industry, but industry which continually revolutionises commerce. The commercial supremacy itself is now conditioned on the greater or smaller prevalence of the conditions for a large industry. Compare for instance, England and Holland. The history of the decline of Holland as the ruling commercial nation is the history of the subordination of merchants' capital to industrial capital. The obstacles presented by the internal solidity and articulation of precapitalistic, national, modes of production to the corrosive influence of commerce is strikingly shown in the intercourse of the English with India and China. The broad basis of the mode of production is here formed by the unity of small agriculture and domestic industry, to which is added in India the form of communes resting upon common ownership of the land, which, by the way, was likewise the original form in China. In India, the English exerted simultaneously their direct political and economic power as rulers and landlords, for the purpose of disrupting these small economic organisations. The English commerce exerts a revolutionary influence on these organisations and tears them apart only to the extent that it destroys by the low prices of its goods the spinning and weaving industries, which are an archaic and integral part of this unity. And even so this work of dissolution is proceeding very slowly. It proceeds still more slowly in China, where it is not backed up by any direct political power on the part of the English. The great economy and saving in time resulting from the direct connection of agriculture and manufacture offer here the most dogged resistance to the products of great industries, whose

prices are everywhere perforated by the dead expenses of their process of circulation. On the other hand, Russian commerce, unlike the English, leaves the economic basis of Asiatic production untouched.

The transition from the feudal mode of production takes two roads. The producer becomes a merchant and capitalist, in contradistinction from agricultural natural economy and the guild-encircled handicrafts of medieval town industry. This is the really revolutionary way. Or, the merchant takes possession in a direct way of production. While this way serves historically as a mode of transition — instance the English clothier of the 17th century, who brings the weavers, although they remain independently at work, under his control by selling wool to them and buying cloth from them — nevertheless it cannot by itself do much for the overthrow of the old mode of production, but rather preserves it and uses it as its premise. For example, even up to the middle of the 19th century the manufacturer in the French silk industry and in the English hosiery and lace industries was but nominally a manufacturer, and merely a merchant in point of fact, who permitted the weavers to continue their work in the old unorganized way and exerted only the control of the merchant, for whom they work in reality. This method is everywhere an obstacle to a real capitalist mode of production and declines with the development of the latter. Without revolutionising the mode of production, it deteriorates merely the condition of the direct producers, transforms them into mere wage workers and proletarians under worse conditions than those who have already been placed under the immediate control of capital and absorbs their surplus-labor on the basis of the old mode of production. The same conditions exist in a somewhat modified form in the London furniture industry, so far as it is carried on by handicrafts. Particularly in the Tower hamlets it is practised on a very extensive scale. The whole production is divided into numerous separate lines independent of one another. One business makes only chairs, another only tables, a third only bureaus, etc. But these lines of business themselves are run more or less like crafts, by one small master with a few journeymen. Nevertheless the output is too large to work directly for private persons. The products are bought by owners of furniture stores. On Saturdays the master sees them and sells his product, and the transaction is closed with as much haggling as is done in a pawnshop over the loan on this or that piece. The masters need this weekly sale, were it for no other reason than to buy more raw materials for next

week and pay wages. Under these circumstances, they are really only middlemen between their employees and the merchants. The merchant is the real capitalist, who pockets the largest share of the surplus-value.

A similar condition exists in the transition to manufacture from lines, which were formerly carried on as handicrafts or as sidelines to rural industries. According to the development of such small independent businesses — which may even employ machinery that admits of a craftslike operation — the transition to large scale industry takes place. The machine is driven by steam, instead of by hand. This is the case, for instance, of late in the English hosiery industry.

There is, consequently, a threefold transition. First, the merchant becomes directly an industrial capitalist. This is the case in crafts conditioned on commerce, especially industries producing luxuries, which are imported by the merchants together with the raw materials and laborers from foreign countries, as they were in Italy from Constantinople in the 15th century. In the second place, the merchant converts the small masters into his middlemen or, perhaps, buys direct from the self-producer, leaving him nominally independent and his mode of production unchanged. In the third place, the industrial becomes a merchant and produces immediately on a large scale for commerce.

In the Middle Ages, the merchant is merely the man who, as Poppe correctly says, “removes” the goods produced by the guilds or the peasants. The merchant becomes an industrial capitalist, or rather, he lets the craftsmen, particularly the small rural producers, work for him. On the other hand, the producer becomes a merchant. The master weaver, instead of receiving his wool in installments from the merchant and working for him with his journeymen buys wool or yarn himself and sells his cloth to the merchant. The elements of production pass into his process of production as commodities bought by himself. And instead of producing for the individual merchant, or for definite customers, the master cloth-weaver produces for the commercial world. The producer is himself a merchant. The merchants’ capital performs no longer anything but the process of circulation. Originally the commerce was the premise for the transformation of the crafts, rural domestic industries, and feudal agriculture into capitalist enterprises. It develops the products into commodities, either by creating a market for them, or by carrying new equivalents in the form of goods to them and supplying production with new raw and auxiliary materials. In

this way it opens up new lines of production, which are based at the outset upon commerce, both as concerns the production for the home and world market and as concerns conditions of production originated by the world market. As soon as manufacture gains sufficient strength, and still more large scale industry, it creates in its turn a market for itself and captures it with its commodities. Now commerce becomes the servant of industrial production, and a continual expansion of the market becomes a vital necessity for industrial production. An ever more extended wholesale production floods the existing market and thereby works continually toward a still wider expansion of the market and a bursting of its bonds. What restricts this wholesale production, is not commerce (to the extent that it expresses the existing demand), but the magnitude of the employed capital and the developed productivity of labor. The industrial capitalist always has the world market before him, compares, and must continually compare, his own cost-prices with those of the whole world, not only with those of his home market. In former periods this comparison falls almost entirely upon the shoulders of the merchants, and thereby secures for merchants' capital the supremacy over industrial capital.

The first theoretical treatment of modern modes of production — the mercantile system — started out necessarily from the superficial phenomena of the process of circulation, which are presented in an independent form by the movements of merchants' capital. Therefore it grasped only the semblance of things. This was partly due to the fact that merchants' capital is the first free mode of existence of capital in general. On the other hand, it was due to the overwhelming influence exerted by this capital during the first period of revolution of feudal production, the period of genesis of modern production. The real science of modern economy does not begin, until theoretical analysis passes from the process of circulation to the process of production. It is true, interest-bearing capital is likewise a very old form of capital. But we shall see later, why mercantilism did not take its departure from it, but assumed a controversial attitude towards it.

**PART V. DIVISION OF PROFIT INTO
INTEREST AND PROFITS OF ENTERPRISE.
THE INTEREST-BEARING CAPITAL.**

CHAPTER XXI. THE INTEREST-BEARING CAPITAL.

IN our first discussion of the general, or average, rate of profit in Part II of this volume, we did not have this rate before us in its complete form, since the equalisation of profit appeared there only as an equalisation between the various industrial capitals invested in different spheres. This was further supplemented in the preceding Part, in which the participation of merchants' capital in this equalisation and the commercial profit were discussed. By this means the general rate of profit and the average profit presented themselves within more circumscribed limits than before. In the further process of our analysis it should be remembered, that any future reference to the general rate of profit or to the average profit means only this latter, completed, form of the average rate. Since this rate is now the same for the industrial and the mercantile capital, it is no longer necessary, so far as this average profit is concerned, to make any distinction between industrial and commercial profit. Whether capital is invested industrially in the sphere of production, or commercially in the sphere of circulation, it yields the same average profit annually in proportion to its magnitude.

Money — which signifies here any independent expression of a certain amount of value, whether it exists actually as money or as commodities — may be converted into capital on the basis of capitalist production. By this conversion it is transformed from a given value to a self-expanding, increasing, value. It produces a profit, that is, it enables a capitalist to extract a certain amount of unpaid labor, surplus-products and surplus-value, from the laborers and to appropriate it to himself. In this way it acquires, aside from its use-value as money, an additional use-value, namely that of serving as capital. Its use-value consists then precisely in the profit, which it produces when converted into capital. In this capacity of potential capital, of a means for the production of profit, it becomes a commodity, but a commodity of a peculiar kind. Or, what amounts to the same, capital as capital becomes a commodity.

Take it that the average rate of profit is 20%. In that case a machine, valued at 100 p.st., employed as capital under the prevailing average conditions and with an average exertion of intelligence and adequate activity, would yield a profit of 20 p.st. In other words, a man having 100

p.st. at his disposal, holds in his hand a power by which 100 p.st. may be turned into 120 p.st., or by which a profit of 20% may be produced. He holds in his hand a potential capital of 100 p.st. If this man relinquishes these 100 p.st. for one year to another man, who uses this sum actually as capital, he gives him the power to produce a profit of 20%, a surplus-value, which costs this other nothing, for which he pays no equivalent. If this man should pay, say 5 p.st. at the close of the year to the owner of the 100 p.st., out of the produced profit, he would be paying for the use-value of the 100 p.st., the use-value of its function as capital, the function of producing 20 p.st. of profit. That part of the profit, which he pays to the owner, is called interest. It is merely another name, a special term, for a certain part of the profit, which capital in process of its function has to give up to its owner, instead of keeping it in its own pockets.

It is evident, that the possession of 100 p.st. gives to their owner the power to absorb the interest, a certain portion of the profit produced by his capital. If he did not give the 100 p.st. to the other man, then this other could not produce any profit, and could not act in the capacity of capitalist at all with reference to these 100 p.st.

To speak in such a case of natural justice, as Gilbart is doing (see note), is nonsense. The justice of the transactions between the agents of production rests on the fact that these transactions arise as natural consequences from the conditions of production. The juristic forms, in which these economic transactions appear as activities of the will of the parties concerned, as expressions of their common will and as contracts which may be enforced by law against some individual party, cannot determine their content, since they are only forms. They merely express this content. This content is just, whenever it corresponds, and is adequate, to the mode of production. It is unjust, whenever it contradicts that mode. Slavery on the basis of capitalist production is unjust; likewise fraud in the quality of commodities.

The 100 p.st. produce the profit of 20 p.st. by functioning as capital, whether it be industrial or commercial. But the indispensable condition of this function as capital is that this money is used as capital, that this money is invested in the purchase of means of production (in the case of industrial capital), or of commodities (in the case of merchants' capital). But in order to be expended, it must be there. If A, the owner of the 100 p.st., were to

spend them for his private expenses, or to keep them as a hoard, they could not be invested by B, in his capacity as a capitalist, as capital. B does not invest his own capital, but that of A. But he cannot expend the capital of A without the consent of A. Therefore it is really A, who first expends these 100 p.st. as capital, although his whole function as a capitalist is limited to this expenditure of 100 p.st. as capital. So far as these 100 p.st. are concerned, B acts in the capacity of a capitalist only because A lends him this money and thus expends it as capital.

Let us first consider the peculiar circulation of interest-bearing capital. Then we shall analyse in the second place the peculiar manner, in which it is sold as a commodity, being merely lent instead of relinquished for good.

The point of departure is the money, which A advances to B. This may be done with or without security. However, the first named form is the more ancient, with the exception of advances on commodities or on certificates of indebtedness, such as bills of exchange, bonds, etc. These special forms do not concern us here. We are dealing here with interest-bearing capital in its ordinary form.

In the hand of B, the money is actually converted into capital, passes through the process $M - C - M'$, and returns as M' to A, as $M +$ increment of M , where the increment of M represents the interest. For the sake of simplicity we leave out of consideration the case, in which capital stays in the hands of B for a long term and interest is paid at periodical intervals.

The movement, then, is $M - M - C - M' - M'$. What appears duplicated here is 1) the expenditure of the money as capital, 2) its reflux as realised capital, as M' , or as $M +$ increment of M .

In the movement of merchants' capital, $M - C - M'$, the same commodity changes hands twice, or even more than twice, if one merchant sells to another. But every change of hand of these commodities indicates a metamorphosis, a purchase or sale of commodities, no matter how often this process may be repeated until it ends in consumption.

On the other hand, the same money changes hands twice in $C - M - C$, but this indicates the complete metamorphosis of the commodity, which is first converted into money and then from money back into another commodity.

But in the case of interest-bearing capital, the first change of hands of M is not a phase of either the metamorphosis of a commodity or of the

reproduction of capital. It does not become so until the second change of hands, in the hands of the man acting in the capacity of a capitalist, who carries on a trade with it or transforms it into productive capital. The first change of hands of M does not express anything else in this case but its transfer, or handing over by contract, from A to B. This is a transfer, which usually takes place under certain juristic forms and stipulations.

This duplicated expenditure of money as capital, the first of which is merely a transfer from A to B, is supplemented by the duplication of its reflux. As M' , or $M + \text{increment of } M$, it flows back out of the process to the man acting in the capacity of a capitalist. This man in his turn transfers it back to A, together with a part of the profit, of realised capital, of $M + \text{increment of } M$, which, however, is not equal to the entire profit, but only a part of the profit, the interest. It flows back to B only as the thing which he had invested, as capital in process of function, but as the property of A. In order that its reflux may be complete, B must return it to A. But B has not only to return the amount of the capital, he must also turn over to A a part of the profit, which he made with this capital, and this part is called interest. For A gave him this money only as a capital, that is, as a value, which is not only maintained by its movements, but brings also a surplus-value to its owner. It remains in the hands of B only so long as it is performing its function of capital. And it ceases to be capital as soon as it is returned to its owner on the stipulated date. When no longer serving as capital, it must be returned to A, who never ceased being its legal owner.

The form of lending, which is peculiar to this commodity, this capital as a commodity, and which also occurs in other transactions instead of that of sale, follows from the simple definition that capital serves here as a commodity, or that money as capital becomes a commodity.

It is necessary to make a distinction here.

We have seen in Volume II, chapter I, and recall at this point, that capital serves in the process of circulation as commodity-capital and money-capital. But in neither of these forms does capital become a commodity as capital.

As soon as the productive capital has transformed itself into commodity-capital, it must be thrown upon the market, it must be sold as a commodity. There it serves simply in the capacity of a commodity. The capitalist then appears only as a seller of commodities, just as the buyer is only a buyer of commodities. As a commodity, the product must realise its value in the

process of circulation, by its sale, must assume the form of money. In this respect it is quite immaterial, whether this commodity is bought by a consumer for the purpose of subsistence, or by a capitalist as a means of production to become a part of his capital. In the act of circulation, the commodity-capital serves only as a commodity, not as capital. It is a commodity-capital, as distinguished from a simple commodity, 1), because it is pregnant with surplus-value, so that the realisation of its value is simultaneously a realisation of surplus-value. But this does not alter in any way its simple existence as a commodity, as a product of a certain price. 2) It is a commodity-capital, because its function as a commodity is a phase in its process of reproduction as capital, so that its movement as a commodity, being a part of its movement in process, is simultaneously its movement as capital. Yet it does not become capital by the act of selling as such, but only through the connection of this act with the whole movement of this definite amount of value in the capacity of capital.

In like manner it serves only as money pure and simple, when acting in the capacity of money-capital, that is, as a means of buying commodities (the elements of production). The fact that this money is at the same time money-capital, a form of capital, is not due to the act of buying, which is the service performed by it as money. It is due to the connection of this act with the total movement of capital, since this act, which it performs as money, inaugurates the capitalist process of production.

But so far as they perform any service and play any actual role in the process, commodity-capital on the market serves only as a commodity, money-capital only as money. At no time during the metamorphosis, viewed by itself, does the capitalist sell his commodities as capital to the buyer, although they represent a capital for himself, nor does he give up money to the sellers in his capacity as a capitalist. In either case he exchanges his commodities simply as commodities, and the money simply as money, as a means of purchasing commodities.

It is only in the connection with the whole process, at the moment where the point of departure appears simultaneously as the point of return, in $M - M'$ or $C - C'$, that capital in the process of circulation appears as capital (while it appears as capital in the process of production through the subordination of the laborer under the capitalist and the production of surplus-value). In this moment of return, however, the connection disappears. What is present is M' , that is money plus increment of money

(regardless of whether the amount of value increased by this increment has the form of money, commodities, or elements of production), a certain amount of money equal to the amount originally advanced plus an increment, which is the realised surplus-value. And it is precisely at this point of return, where capital exists as a realised capital, as an expanded value, that capital never passes into circulation — considering this point as a fixed point of rest, whether imaginary or real — , but rather appears to be withdrawn from circulation as a result of the whole process. Whenever it is again relinquished, it is never transferred to another as capital, but sold to him as a simple commodity, or given to him as simple money in exchange for commodities. It never appears as capital in its process of circulation, but only as a commodity or as money, and this is the only form in which it exists so far as others are concerned. Commodities and money are here capital, not inasmuch as commodities change into money, or money into commodities, not with reference to their actual relations to sellers or buyers, but only with reference to their ideal relations, that is, subjectively speaking, their relations to the capitalist himself, or objectively speaking, as elements of the process of reproduction. So far as capital is capital, it exists only in its actual function, not in the process of circulation, but only in the process of production, in the process by which labor-power is exploited.

But it is different with interest-bearing capital, and it is precisely this difference, which constitutes its specific character. The owner of money, who desires to invest his money as interest-bearing capital, transfers it to some one else, throws it into circulation, makes a commodity of it as capital. It is not a capital for himself alone, but also for others. It is not capital merely for the man who offers it for investment, but it is handed to others at the outset as capital, as a value endowed with the use-value of creating surplus-value, profit; a value which preserves itself in process and returns to its original owner, in this case the owner of money, after performing its function. It moves away from him only for a certain time, it passes for a while from the possession of its owner into that of a capitalist performing his business, it is neither given up in payment nor sold, but merely loaned. It is relinquished only with the understanding that it shall in the first place return to its point of departure after a certain time, and that it shall return, in the second place, as realised capital, a capital having actually performed its function of creating surplus-value.

Commodities, which are loaned out as capital, are loaned either as fixed or as circulating capital, according to their constitution. Money may be loaned in either form. For instance, it may be loaned as fixed capital in the form of an annuity, whereby a portion of the capital returns with the interest. Some commodities, owing to the nature of their use-values, can be loaned only as fixed capital, such as houses, ships, machines, etc. But all loan capital, whatever be its forms, and no matter in what manner the nature of its use-value may modify its return, is only a specific form of money-capital. For the thing that is loaned here is always a definite sum of money, and it is this sum on which interest is calculated. If the thing that is loaned is neither money nor circulating capital, it is paid back in the same way in which fixed capital returns. The lender receives periodically a certain interest and a portion of the consumed value of the fixed capital itself, an equivalent for the periodical wear and tear. And at the end of the stipulated term the unconsumed portion of the loaned fixed capital is returned in natura. If the loaned capital is circulating capital, it is like-wise returned in the manner peculiar to circulating capital.

The manner of reflux, then, is always determined by the actual circulation of the capital in process of reproduction and its specific kind. But so far as loan capital is concerned, its reflux assumes the form of return payments, because its advance, by which it is relinquished, has the form of loaning.

In this chapter we treat only of money-capital proper, from which the other forms of loaned capital are derived.

The loaned capital returns in a twofold way. First it returns in the process of reproduction to the capitalist performing his function, and then its return is duplicated by its transfer to the lender, the money-capitalist, in the form of a return payment to its real owner, its legal point of departure.

In the actual process of circulation the capital appears always as a commodity or as money, and its movements are always dissolved into a series of purchases and sales. In short, the process of circulation resolves itself into the metamorphosis of commodities. It is different, when we consider the process of reproduction as a whole. If we take our departure from money (and it is the same, when we start off with commodities, since we then take our departure from their value and look upon them from the point of view of money), we see that a certain sum of money is expended and returns after a certain period with an increment. This sum has preserved

itself and expanded itself in the course of a certain rotation. To the extent that money is loaned as capital, it is loaned as just such a sum of money, which preserves and expands itself, returns after a certain period with an increment, and is ready to pass through the same process once more. It is not expended either as money or as a commodity, it is neither exchanged for commodities when advanced in the form of money, nor sold in exchange for money, when advanced in the form of commodities. It is expended as capital. This reflexive relation to itself, in which capital presents itself when the process of production is viewed in its entirety and as a unit, and in which money appears as self-increasing money, is here imposed upon it as its character and peculiarity without the intervention of any intermediary movement. And it is expended in this peculiar form, when it is loaned as money-capital.

A very queer conception of the role of money-capital is held by Proudhon “*Gratuité du Crédit. Discussion entre M. F. Bastiat et M. Proudhon.* Paris, 1850.”) Loaning appears as an evil to Proudhon because it is not selling. Loaning at interest is for him “the faculty of always selling the same article over and over, and of receiving its price again and again, without ever relinquishing the ownership of the things one is selling” (page 9). The object, such as money, a house, etc., does not change owners, as it does in selling and buying. But Proudhon does not see, that no equivalent is received for money handed over as interest-bearing capital. It is true that objects are passed from one to another in every act of buying and selling, so far as they are at all processes of exchange. The ownership of the sold object is always relinquished. But its value is not given up. In selling the commodity is relinquished, but not its value, which is given in return in the form of money, or in another form which here takes the place of money, namely of certificates of indebtedness, or of titles of payment. In buying money is given away, but its value, which is recovered in the shape of commodities. The industrial capitalist holds the same value in his hands during the entire process of reproduction (except the surplus-value), only it assumes different forms.

To the extent that exchange takes place, that is, an exchange of objects, no change of value takes place. The same capitalist always holds the same value in his hands. But so long as surplus-value is produced by the capitalist, no exchange takes place. As soon as exchange takes place, the surplus-value is already incorporated in the commodities. If we do not have

in mind the individual acts of exchange, but the total circulation of capital, $M - C - M'$, we see that a definite amount of values is continually advanced, and that this amount plus the surplus-value, or the profit, is recovered from the circulation. It is true, the individual acts of exchange do not reveal the fact that they are promoting this process. And it is precisely this process of M as capital, on which the interest of the money-lending capitalist rests and from which it arises.

“In fact,” says Proudhon, “the hat maker, who sells hats...receives their value, no more and no less. But the money-lending capitalist...does not recover merely his capital: he recovers more than his capital, more than he throws into circulation; he receives an interest over and above his capital.” (Page 169.) The hatter stands here in the place of the productive capitalist as distinguished from a loan capitalist. Evidently Proudhon did not learn the secret, which enables the capitalist to sell commodities at their value (the equalisation of values by the prices of production is here immaterial for his conception), whereby he receives a profit in addition to the capital, which he throws into circulation. Let us assume that the price of production of 100 hats is 115 pounds sterling, and that this price of production happens to be identical with the value of the hats, which means that the capital invested in the production of hats is of the same composition as the average social capital. If the profit is 15 p.st., or 15%, then the hatter gets this profit of 15 p.st. by selling his hats at their value of 115. They cost him 100 p.st. If he has produced them with his own capital, he pockets the whole surplus of 15 p.st. If he has borrowed the capital, he may have to give up 5 p.st. for interest. This does not alter anything in the value of the hats, but only in the distribution of the surplus-value already contained in this value between different persons. Since the value of the hats is not affected by the payment of interest, it is nonsense on the part of Proudhon to say: “As in commerce the interest of capital is added to the wages of laborers in making up the price of commodities, it is impossible that the laborer should be able to buy back the product of his own labor. To live by working is a principle, which implies a contradiction under the rule of interest.”

How little Proudhon understood the nature of capital, is shown by the following statement, in which he describes the movement of capital in general as a movement peculiar to interest-bearing capital: “Since money-capital, from exchange to exchange, comes always back to its source by the

accumulation of interest, it follows that re-investment is always made by the same hand and profit accrues always to the same person.”

What is it, now, that remains a riddle to him in the peculiar movement of interest-bearing capital? The categories buying, price, giving up objects, and the spontaneous form, in which surplus-value appears here; in short, the phenomenon that capital as such has become a commodity, so that selling has been turned into lending and price into a share in the profit.

The return of capital to its point of departure is the most general and characteristic movement of capital in its total circulation. This is by no means a peculiarity of interest-bearing capital. Its peculiarity is rather the externalised form of its return without the intervention of any circulation. The loaning capitalist lets go of his capital, transfers it to some industrial capitalist, without receiving any equivalent. His handing over of capital is not an act of the real circulation of capital at all, but serves merely as a prelude for the industrial capitalist who effects this circulation. This first change of place of money does not express any act of metamorphosis, neither buying nor selling. Its ownership is not relinquished, because no exchange takes place, no equivalent is offered. The return of the money from the hand of the industrial capitalist to that of the loaning capitalist supplements merely the first act of handing over the capital. This capital, after having been advanced in the form of money, returns to the industrial capitalist from the process of circulation in the form of money. But as the capital did not belong to him when he expended it, neither can it belong to him on its return. The passage through the process of reproduction cannot by any means give him the ownership of this capital. Hence he must restore it to its lender. The first transfer of the capital from the hands of the lender to those of the borrower is a legal transaction, which has nothing to do with the actual process of reproduction, but merely inaugurates it. The restoration, which transfers the returned capital from the hands of the borrower back to those of the lender is another legal transaction, a supplement of the first. The first inaugurates the actual process, the second takes place after this process. The point of departure and of return, the dispensation and recovery of the loaned capital, thus appear as arbitrary movements promoted by legal transactions, which take place before and after the actual process of capital and have nothing to do with it. So far as this actual process is concerned, the industrial capitalist might as well own the capital at the outset, so that it would return to him as his property.

In the first introductory act the lender gives his capital to the borrower. In the second and closing act after the process, the borrower returns the capital to the lender. To the extent that we consider merely the transaction between these two — and leaving aside the question of interest for the present — , in other words to the extent that we have in mind only the movement of the loan capital itself between the lender and the borrower, the whole movement is comprised within these two acts (separated by a longer or shorter time, during which the process of actual reproduction of capital takes place). And this movement, this dispensing on condition of returning, constitutes per se the movement of lending and borrowing, which is a specific form of a conditional dispensation of money or commodities.

The characteristic movement of capital in general, namely the return of money to the capitalist, the return of capital to its point of departure, assumes in the case of interest-bearing capital a wholly externalised form, separated from the actual movement of which it is an expression. A lets go of his money, not in the sense of money, but of capital. This implies no transformation of the capital. It merely changes hands. Its real transformation into capital is not performed until it is in the hands of B. But it has become capital for A as soon as he has given it to B. The actual reflux of capital from the processes of production and circulation takes place only for B. But for A the reflux assumes the same form as the dispensation. The capital returns from the hands of B to those of A. Dispensing, loaning money for a certain time and recovering it with interest (surplus-value) make up the complete form of the movement, which is peculiar to interest-bearing capital as such. The actual movement of the loaned money as capital constitutes a process, which is outside of the transactions between the lender and the borrower. In these transactions the intermediate process is obliterated, invisible, not directly comprised.

Being a peculiar sort of commodity, capital has its own peculiar mode of alienation. Its return in the present case is not the expression, not the consequence or result, of a definite series of economic processes, but the outcome of a specific legal agreement between buyer and seller. The time of return depends on the duration of the process of reproduction. But in the case of interest-bearing capital, its return as capital seems to depend on the mere agreement between lender and borrower. The return of capital as a part of this agreement no longer appears as a result due to the process of reproduction, but seems to take place without depriving the loaned capital

of the form of money. It is true that these transactions are actually determined by the reproductive returns. But this is not evident in the transactions themselves. Nor is it always the case in practice. If the return in reproduction does not take place at the proper time, then the borrower has to face the problem. what other resources he can call into play to fulfill his obligations towards the lender. The mere form of this capital — that is, money expended as a certain sum, A , and returning as another sum $A + IA/x$, after a certain lapse of time, without any other intermediate connection but this lapse of time — is but an abstract image of the actual movement of capital.

In the actual movement of capital, its return is a phase of the process of circulation. The money is first converted into means of production; the process of production transforms it into commodities; by the sale of the commodities it is reconverted into money, and in this form it returns to the hands of the capitalist, who originally advanced the capital in the form of money. But in the case of interest-bearing capital, both the alienation and the return are the results of a legal transaction between the owner of capital and another person. We see only the alienation and the return. Whatever passes during the interval is obliterated.

But since money, when advanced as capital, has the faculty of returning to the person, who expended it as capital, since $M — C — M'$ is the immanent form of the movement of capital, for this very reason the owner of money can loan it as capital, a thing having the faculty of returning to its point of departure, of preserving its value while under way in process, and of increasing it. He loans it as capital, because it returns to its point of departure after having been transformed into capital, so that the borrower can restore it to the lender after a certain period, because he has recovered it himself.

The loaning of money as capital — its alienation on condition that it be returned after a certain time — is therefore conditioned on the requirement that this money be actually employed as capital, so that it may actually flow back to its starting point. The actual cycle of money as capital is therefore the basic condition of the legal transaction, by which the borrower has to return the money to the lender. If the borrower does not invest the money as capital, it is his own business. The lender loans it as capital, and as such it is supposed to perform the capitalist functions, which include the

circulation of money-capital until it reaches once more its starting point in the form of money.

The transactions $M - C$ and $C - M'$ in the circulation, in which a certain amount of value serves as money or commodities, are but intermediary processes, individual phases of a whole movement. As capital, this sum passes through the whole movement $M - M'$. It is advanced as money, or as a sum of values in some form, and returns as a sum of values. The lender of money does not expend it in the purchase of commodities, or, if this sum of values exists in the form of commodities, he does not sell it for money, but he advances it as capital, as $M - M'$, as a value, which returns after a certain lapse of time to its point of departure. Instead of buying and selling, he loans. This loaning, then, is the form corresponding to its alienation as capital, instead of its alienation as money or commodities. This does not mean, however, that loaning may not be used in transactions, which have nothing to do with the capitalist process of reproduction.

We have so far considered only the movements of loaned capital between its owner and the industrial capitalist. Now we shall have to inquire into interest.

The lender expends his money as capital; the amount of values, which he relinquishes into the hands of another, is capital and returns to him. But the mere return of the loan capital into his hands as the same amount would not be its reflux as capital, but merely the return of a loaned sum of values. In order to return as capital, the advanced sum of values must not only be preserved in process, but must also be expanded, must return with a surplus-value, must be recovered as $M + \text{increment of } M$. This increment of M is in the present case the interest. It is that portion of the average profit, which does not remain in the hands of the practicing capitalist, but falls to the share of the money capitalist.

The fact that the money capitalist expends it as capital implies that it must be restored to him as $M + \text{increment of } M$. Later we shall also have to consider the case, in which interest is paid in fixed intervals without the simultaneous return of the capital, whose definite return does not take place until at the end of a longer period.

What is it that the money capitalist gives to the borrower, the industrial capitalist? What does he really pass over to him? It is only this transaction

of handing over money which makes of the loaning of money a lending of money as capital, that is, the lending of capital as a commodity.

It is only by this act of passing money over to another that the capital is loaned by the money lender as a commodity, or that the commodity at his disposal is given to another as capital.

What is it that is alienated in ordinary sale? It is not the value of the sold commodities, for this changes merely its form. The value exists ideally in a commodity as its price, before it passes actually into the hands of the seller as money. The same value and the same amount of value merely change their form in such a case. In one instance they exist in the form of a commodity, in another in the form of money. The thing which is actually alienated by the seller, and which for this reason passes into the individual or productive consumption of the buyer, is the use-value of the commodity, is the commodity as a use-value.

What, then, is the use-value, which the money capitalist passes over for the period of the loan and relinquishes into the hands of the borrower, the productive capitalist? It is the use-value, which the money assumes by being capable of being invested as capital and performing the functions of capital, so that it can create a definite surplus-value, the average profit (any excess or fall below this is here a matter of accident), during its process, in addition to preserving its original magnitude of value. In the case of other commodities the use-value is ultimately consumed. Their substance disappears in consequence and with it their value. But the commodity capital has the peculiarity, that the consumption of its use-value not only preserves its exchange value and its use-value, but also increases them.

It is this use-value of money as capital, this faculty of producing an average profit, which the money capitalist relinquishes to the industrial capitalist for the period, during which he yields to the latter the use of the loan capital.

The money thus loaned shows in this respect a certain analogy with labor-power in its relation to the industrial capitalist. There is only this difference, that he pays for the value of labor-power, while he simply pays back the value of the loaned capital. The use-value of labor-power consists for the industrial capitalist in the faculty that labor-power creates more value (the profit) by its consumption for the industrial capitalist. And in like manner the use-value of the loan capital appears as its faculty of preserving and increasing value.

The money-capitalist alienates indeed a use-value, and for this reason the thing which he gives away is given as a commodity. And to this extent the analogy with a commodity is complete. In the first place, it is a value, which passes from one hand to another. In the case of a simple commodity, a commodity as such, the same value remains in the hands of the buyer and seller, only it has different forms; both have the same value which they had before the transaction, the one in the form of a commodity, the other in that of money. The difference in the case of loan capital is that the money capitalist is the only one who gives away a value when loaning money; but he preserves it by means of future restoration. In the transaction of loaning only one party receives value, since only one party relinquishes value.

In the second place, it is a real use-value, which is relinquished on one side and received and consumed on the other. But it differs from the use-value of ordinary commodities in that it is itself a value, namely the excess over the value of the original capital realised by the use of money as capital. The profit is this use-value.

The use-value of the loan capital consists in being able to serve as capital and to produce in this capacity the average profit under average conditions.

What, then, does the industrial capitalist pay, and what is, therefore, the price of the loaned capital? That which men pay as interest for the use of what they borrow is, according to Massie, a part of the profit it is capable of producing.

What the buyer of an ordinary commodity buys is its use-value; what he pays for is its exchange value. What the borrower of money buys, is likewise its use-value as capital; but what does he pay for? Surely not for its price, or value, as in the case of ordinary commodities. No change of form takes place in the value passing between the borrower and the lender, such as takes place between the buyer and the seller, so that this value would exist in one instance in the form of money, in another instance in the form of a commodity. The sameness of the alienated and returned value shows itself here in an entirely different way. The sum of values, the money, is given away without an equivalent, and is returned after the lapse of a certain period. The lender always remains the owner of the same value, even after it has passed from his hands into those of the borrower. In the simple exchange of commodities, the money is always on the side of the buyer; but in the lending, the money is on the side of the lender. It is he, who gives

away his money for a certain period, and it is the borrower, the buyer of capital, who receives it as a commodity. But this is possible only when the money serves as capital and is advanced for this purpose. The borrower borrows money as capital, as a value producing an increment. But at the moment of borrowing it is as yet only potential capital, and so is any other capital at the moment when it is advanced. Only by its use does it expand its value and realise itself as capital. But after it has become realised capital, the borrower has to return it, as a value plus a surplus-value (interest). And this interest can be only a portion of the realised profit. Only a portion, not the whole of it. For its use-value for the borrower consists in producing a profit for him. Otherwise there would not have been any alienation of its use-value on the part of the lender. On the other hand, it cannot be the whole profit which falls to the share of the borrower. Otherwise he would not be paying anything for the alienation of the use-value, and he would return the advanced money to the lender as simple money, not as a capital having realised itself. For it is realised capital only when it is $M +$ increment of M .

Both of them expend the same sum of money as capital, the lender and the borrower. But only in the hands of the latter does it serve as capital. The profit is doubled by the double existence of the same sum of money as a capital for two persons. It can serve as a capital for both of them only by dividing the profit. That portion, which falls to the share of the lender, is called interest.

It is our assumption, that this entire transaction takes place between two kinds of capitalists, the money-capitalist and the industrial or the merchant capitalist.

It should never be forgotten, that capital as such is here a commodity, or that the commodity, which is here in question, is capital. All the relations, which become manifest here, would be irrational from the point of view of a simple commodity, or even from the point of view of capital serving as a commodity-capital in its process of reproduction. Lending and borrowing, instead of selling and buying, is here a distinction arising from the specific nature of the commodity, of capital; also that it is interest, not the price of the commodity, which is paid here. If interest is to be called the price of money-capital, it will be an irrational form of price, which is quite at variance with the conception of the price of commodities. The price is then reduced to its purely abstract and meaningless form, signifying a certain

sum of money paid for some thing, which serves in some manner as a use-value. On the other hand, the concept of price really signifies the value of some use-value expressed in money.

To call interest the price of capital is to use at the outset an irrational expression. A commodity has here a double value, namely first a real value, and secondly a price differing from this value, while ordinarily price signifies the expression of the value in money. Money-capital is primarily but a sum of money, or the value of a certain quantity of commodities incorporated in a sum of money. If a commodity is loaned as capital, then it is only the disguised form of a sum of money. For that which is loaned as capital is not so and so many pounds of cotton, but so much money existing in the form of cotton as its value. The price of capital, therefore, refers to it as a sum of money, even if not a currency, as Mr. Torrens thinks (see above note 60). How, then, can a sum of values have a price beside its own price, that is, aside from the price expressed in their own money-form? Price is precisely the value of commodities (and this holds good also of the market-price, whose difference from value is not one of quality, but only one of quantity, since it refers only to the magnitude of the value) as distinguished from their use-value. A price which is different in quality from value is an absurd contradiction.

Capital manifests itself as capital by its employment. The degree of its self-expansion expresses the quantitative ratio, in which it realises itself as capital. The surplus-value or profit produced by it — its rate or magnitude — is measurable only by its comparison with the value of the advanced capital. The greater or lesser self-expansion of interest-bearing capital is, therefore, only measurable by a comparison of the amount of interest, its share in the total profits, with the value of the advanced capital. While the price expresses the value of commodities, the interest expresses the self-expansion of money-capital and thus appears as the price, which the lender receives for it. This shows how absurd it is at the start to apply indiscriminately to this question the simple relations of exchange through buying and selling, as Proudhon does. For the basic premise is here that money serves as capital and may thus be transferred as capital itself, as potential capital, to another person.

Capital itself appears here as a commodity, inasmuch as it is offered on the market as the use-value of money actually handed over as capital. Its use-value consists in producing profits. The value of money or of

commodities employed in the capacity of capital is not determined by their value as money or commodities, but by the quantity of surplus-value, which they produce for their owner. The product of capital is profit. On the basis of capitalist production it is merely a difference in the employment of money, whether it is expended as money or advanced as capital. Money, or commodities, are in themselves, potentially, capital, just as labor-power is potential capital. For in the first place, money may be converted into elements of production and is to that extent only an abstract expression of them, personifying their existence as values; in the second place, the material elements of wealth have the capacity of being even potentially capital, because the opposite supplement, which makes capital of them, namely wage-labor, is present on the basis of capitalist production.

The opposing social peculiarities of material wealth, its antagonism to labor in the form of wage-labor, considered apart from the process of production, are expressed even in capitalist property as such. This particular fact, when separated from the process of capitalist production itself, of which it is a constant result and, being its constant result, is its constant prerequisite, expresses itself in such a way that money and commodities alike become latent, potential, capital, so that they may be sold as capital, and that they represent in this form a command over the labor of others, a claim to the appropriation of the labor of others, so that they become self-expanding values. In this way it also becomes clearly apparent that this relation supplies the title and means for the appropriation of the labor of others, and that this is not due to any labor offered as an equivalent on the part of the capitalist.

Capital appears furthermore as a commodity, inasmuch as the division of profit into interest and profit proper is regulated by demand and supply, that is, by competition, just as are the market-prices of commodities. But in the present case the difference becomes quite as apparent as the analogy. If demand and supply balance, the market-price of commodities corresponds to their price of production. In other words, their price is then seen to be regulated by the internal laws of capitalist production, independently of competition, since the fluctuations of supply and demand do not explain anything but the deviations of market-prices from the prices of production. These deviations balance mutually, so that in the course of long periods the average market-prices correspond to the prices of production. As soon as these prices coincide, these forces cease to operate, they compensate one

another, and the general law determining prices then applies also to individual cases. The market-price then corresponds even in its immediate form, and without the help of averages drawn from the movements of market-prices, to the price of production, which is regulated by the immanent laws of the mode of production itself. The same is then true of wages. If supply and demand balance, they neutralise each other's effects, and wages are then equal to the value of labor-power. But it is different with the interest on money-capital. Competition does not, in this case, determine the deviations from the rule, but there is rather no law of division except that enforced by competition, because no such thing as a "natural" rate of interest exists, as we shall see presently. By the natural rate of interest people merely mean the rate fixed by free competition. There are no "natural" limits for the rate of interest. Whenever competition does not merely determine the deviations and fluctuations, in other words, whenever a neutralisation of the opposing forces of competition puts a stop to all determination, the thing to be determined becomes a matter of arbitrary and lawless estimation. We shall dwell on this further in the next chapter.

In the case of interest-bearing capital, everything is outward appearance: The advance of capital seems a mere transfer from the lender to the borrower; the reflux of realised capital a mere transfer back to its owner, a return payment with interest from the borrower to the lender. The same holds good of the fact, due to the capitalist mode of production, that the rate of profit is not merely determined by the relation of the profit made in one single turn-over to the advanced capital-value, but also by the length of the time of turn-over itself, so that it is a question of a profit realised on the industrial capital in definite periods of time. This likewise appears in the case of interest-bearing capital in the outward fact, that a definite interest is paid to the lender for a definite period of time.

With his customary insight into the internal connection of things, the romantic Adam Müller says (*"Elemente der Staatskunst,"* Berlin, 1809,): "In determining the prices of things, time is not considered; while in the determination of interest, it is principally time which is taken into account." He does not see that the time of production and the time of circulation enter into the determination of the price of commodities, and that this is precisely what determines the rate of profit for a given time of turn-over of capital, while the determination of profit for a certain time in its turn determines that of interest. His sagacity consists here, as it always does, in seeing the

clouds of dust on the surface and having the presumption to declare this dust to be something mysterious and important.

CHAPTER XXII. DIVISION OF PROFIT. RATE OF INTEREST. NATURAL RATE OF INTEREST.

THE object of this chapter, and in general all other phenomena of credit requiring our consideration later on, cannot here be analysed in detail. The competition between lenders and borrowers and the resulting minor fluctuations of the money-market fall outside of the scope of our inquiry. The circle described by the rate of interest during the industrial cycle requires for its presentation the analysis of this cycle itself, but this is likewise beyond our intentions for the present. The same is true of the greater or lesser approximate equalisation of the rate of interest in the world market. We merely intend here to analyse the independent form of interest-bearing capital and the individualisation of interest as differentiated from profit.

Since interest is merely a part of profit, paid according to our assumption by the industrial capitalist to the money-capitalist, the maximum limit of interest is marked by profit itself, and in that case the portion pocketed by the productive capitalist would be equal to zero. Aside from exceptional cases, in which interest might be actually larger than profit and could not be paid out of profit, one might consider as the maximum limit of interest the entire profit minus that portion (to be subsequently analysed), which resolves itself into wages of superintendence. The minimum limit of interest is wholly undefinable. It may fall to any depth. But counteracting circumstances will always appear and lift it again above this relative minimum.

“The relation between the amount paid for the use of some capital and this capital itself expresses the rate of interest, measured in money.” “The rate of interest depends, 1), on the rate of profit; 2), on the proportion in which the total profit is divided between the lender and the borrower.” (Economist, January 22nd, 1853.) “Since that which is paid as interest for the use of that which is borrowed is a part of the profit, which the borrowed is able to produce, this interest must always be regulated by that profit.” (Massie, l. c., .)

Let us first assume, that a fixed relation exists between the total profit and that one of its parts, which has to be paid as interest to the money-capitalist. In this case it is evident, that the interest will rise or fall with the total profit, and this profit is determined by the general rate of profit and its fluctuations. For instance, if the average rate of profit were 20% and the interest one-quarter of the profit, then the rate of interest would be 5%; if the rate of profit were only 16%, the rate of interest would be 4%. With a rate of profit of 20%, the rate of interest might rise to 8%, and yet the industrial capitalist would still make the same profit as he would with the rate of profit at 16% and the rate of interest at 4%, namely 12%. If the interest should rise only to 6 or 7%, he would keep a still larger share of the profit. If the interest amounted to a constant quota of the average profit, it would follow, that to the extent that the general rate of profit would rise, the absolute difference between the total profit and the interest would increase, and to the same extent would that portion of the total profit increase, which the productive capitalist would pocket, and vice versa. Take it that the interest amounts to one-fifth of the average profit. One-fifth of 10 is 2; difference between total profit and interest 8. One-fifth of 20 is 4; difference $20 - 4 = 16$. One-fifth of 25 is 5; difference $25 - 5 = 20$. One-fifth of 30 is 6; difference $30 - 6 = 24$. One-fifth of 35 is 7; difference $35 - 7 = 28$. The different rates of interest of 4, 5, 6, 7% would in this case always represent one-fifth of the total profit. If the rates of profit are different, then different rates of interest may represent the same aliquot parts of the total profit, or the same percentage of the total profit. With such constant proportions of interest, the industrial profit (the difference between the total profit and the interest) would be so much greater, the higher the average rate of profit would be, and vice versa.

Assuming all other conditions to be equal, in other words, assuming the proportion between interest and total profit to be more or less constant, the productive capitalist will be able and willing to pay a higher or lower interest directly proportional to the level of the rate of profit.⁶² Since we have seen, that the height of the rate of profit is inversely proportional to the development of capitalist production, it follows that the high or low rate of interest in a certain country is to the same extent inversely proportional to the degree of industrial development, at least so far as differences in the rate of interest actually expresses differences in the rates of profit. And this mode of regulating interest applies even to its average.

In any event the average rate of profit is the ultimate limit determining the maximum limit of interest.

The fact that the rate of interest is related to the average profit will be considered more at length immediately. Whenever a certain whole, such as profit, is to be divided between two parties, the first thing to be considered is the magnitude of the whole. The magnitude of the profit is determined by its average rate. Assuming the average rate of profit, and thus the magnitude of profit, for a capital of a certain size, to be given (for instance 100), it is evident that the variations of interest will be inversely proportional to those of the profit remaining in the hands of the capitalist working with a borrowed capital. And the circumstances, which determine the amount of profit to be divided (the values produced by unpaid labor), differ widely from those, which determine its distribution between these two kinds of capitalists, and frequently produce effects in opposite directions.⁶³

If we observe the cycles of variation, in which modern industry moves along — condition of rest, increasing activity, prosperity, overproduction, crisis, stagnation, condition of rest, etc., which fall outside of the scope of our analysis — we shall find, that a low rate of interest generally corresponds to periods of prosperity, or of extra profit, a rise of interest to the transition between prosperity and its reverse, and a maximum of interest up to a point of extreme usury to the period of crises.⁶⁴ With the summer of 1843 came a period of remarkable prosperity; the rate of interest, which had still been 4½% in the spring of 1842, fell to 2% in the spring and summer of 1843;⁶⁵ in September it fell even to 1½%. (Gilbart, I,); whereupon it rose to 8% and more during the crisis of 1847.

It may happen, however, that low interest is found in times of stagnation, and moderately rising interest in times of increasing activity.

The rate of interest reaches its highest point during crises, when money must be borrowed in order to meet payments at any cost. Since a rise of interest implies a fall in the price of securities, this offers at the same time a fine opportunity to people with available money-capital, who may acquire possession at cut-rate prices of such interest-bearing securities as must at least regain their average price in the regular course of things, as soon as the rate of interest falls again.⁶⁶

However, there is also a tendency of the rate of interest to fall, quite independently of the fluctuations of the rate of profit. This is due to two main causes.

“Let us assume that capital were never borrowed for any other but productive investments, it is nevertheless possible, that the rate of interest may vary without any change in the rate of gross profits. For, as a people progresses in the development of wealth, there arises and grows more and more a class of people, who find themselves possessed of funds through the labors of their ancestors, and who can live on the mere interest on them. Many, having actively participated in business in their youth and prime, retire, in order to live quietly in their old age on the interest of the sums accumulated by them. These two classes have a tendency to increase with the growing wealth of the country; for those who start out with a moderate capital acquire more easily an independent fortune than those, who start out with little. In old and rich countries, therefore, that portion of the national capital, whose owners do not care to invest it themselves, makes up a larger proportion of the total productive capital of society than in newly settled and poor countries. How numerous is not the class of annuity-holders in England! In proportion as the class of annuity-holders increases, that of the capital loaners increases also, for they are both the same.” (Ramsay, *Essay on the Distribution of Wealth*,)

The development of the credit system, and with it the continually growing control of the industrials and merchants over the money savings of all classes of society by the co-operation of bankers, and the progressive concentration of these savings into such volumes as will enable them to serve as money-capital, must also depress the rate of interest somewhat. We shall discuss this more at length later.

With reference to the determination of the rate of interest, Ramsay says that it “depends in part on the rate of gross profits, in part on the proportion in which this is divided into interest and profits of enterprise. This proportion depends on the competition between lenders and borrowers of capital. This competition is influenced, but not exclusively regulated, by the prospective rate of gross profits.⁶⁷ Competition is not exclusively regulated thereby, because on one side many are borrowing without any intention of productive investment, and because on the other the magnitude of the total loanable capital changes with the wealth of the country, independently of any change in the gross profits.” (Ramsay, *l. c.*, , 207.)

In order to find the average rate of interest, it is necessary, 1), to calculate the average rate of interest during its variations in the great

industrial cycles; 2), to find the rate of interest in such investments as require loans of capital for a long time.

The average rate of interest prevailing in a certain country — as differentiated from the continually fluctuating market rates — cannot be determined by any law. In this sense there is no such thing as a natural rate of interest, such as economists speak of when mentioning a natural rate of profit and a natural rate of wages. Massie has justly said with reference to this : “The only thing which any man can be in doubt about on this occasion, is, what proportion of these profits do of right belong to the borrower, and what to the lender; and this there is no other method of determining than by the opinions of borrowers and lenders in general; for right and wrong, in this respect, are only what common consent makes so.” The balancing of demand and supply — assuming the average rate of profit to be a fact — does not signify anything here. Wherever else this formula serves as an excuse (and is then practically correct) it is used to find the fundamental rule, which is independent of competition and rather determines it, this rule indicating the regulating limits, or the limiting magnitudes, of competition; this formula serves particularly as a help to those, who are bounded by the horizon of practical competition, its phenomena, and the conceptions arising from them, and who try thereby to get a rather shallow grasp of the internal connections of economic conditions within the sphere of competition. It is a method by which to pass from the variations that go with competition to the limits of these variations. This is not so in the case of the average rate of interest. There is no reason by which the idea could be justified, that the average conditions of competition, a balance between lenders and borrowers, should secure for the lender a rate of interest of 3, 4, 5%, etc., on his capital, or a certain percentage of the gross profits, say 20% or 50%. Whenever competition as such determines anything in this matter, its determination is a matter of accident, purely empirical, and only pedantry or fantasticalness can attempt to represent this accidental character as something necessary.⁶⁸ Nothing is more amusing than to listen in the reports of Parliament of 1857 and 1858 concerning bank legislation and commercial crises to the rambling twaddle of directors of the Bank of England, London bankers, provincial bankers, and theoretical professionals, when referring to “the real rate produced.” They never get beyond such commonplaces as that “the price paid by loanable capital probably varies with the supply of such capital,” that “a

high rate of interest and a low rate of profit cannot exist together in the long run,” and similar specious platitudes.⁶⁹ Custom, legal tradition, etc., have as much to do with the determination of the average rate of interest as competition itself, so far as this rate exists not merely as an average figure, but as an actual magnitude. An average rate of profit has to be assumed as a legal rate even in many law disputes, in which interest has to be calculated. Now, if we press the inquiry, why the limits of an average rate of interest cannot be deduced from general laws, we find the answer simply in the nature of interest. It is merely a portion of the average profit. The same capital appears in two roles, as a loanable capital in the hands of the lender, and as an industrial capital, or commercial capital, in the hands of the investing capitalist. But it performs its function as capital only once, and produces profit only once. In the process of production itself, the loanable nature of this capital does not play any role. To what extent the two parties divide the profit, in which they both share, is in itself as much a purely empirical fact belonging to the realm of accident as the division of the shares of common profit of some corporative business among different share holders by percentages. In the division between surplus-value and wages, on which the determination of the rate of profit essentially rests, the decision is made by two very different elements, labor-power and capital; these are functions of two independent variables, which limit one another; and their qualitative difference is the source of the quantitative division of the produced value. We shall see later that the same takes place in the division of surplus-value between rent and profit. But nothing of the kind occurs in the case of interest. In this case the qualitative differentiation, as we shall see immediately, proceeds rather from the purely quantitative division of the same lot of surplus-value.

From what has gone before it follows that there is no such thing as a “natural” rate of interest. But while, in distinction from the general rate of profit, there is on one side no general law, by which the limits of the average interest, or average rate of interest, may be determined and differentiated from the continually fluctuating market rates of interest, because it is merely a question of dividing the gross profit between two possessors of capital under different titles, there is on the other side the fact that the rate of interest, whether it be the average or the prevalent market rate, appears as a uniform, definite and tangible magnitude in a very different way from the general rate of profit.⁷⁰

The rate of interest holds a similar relation to the rate of profit as the market price of a commodity does to its value. To the extent that the rate of interest is determined by the rate of profit, it is so always by the general rate of profit, not by any specific rates of profit, which may prevail in some particular lines of industry, and still less by any extra profit, which some individual capitalist may make in some particular line of business.⁷¹ It is a fact, then, that the general rate of profit re-appears as an empirical, given, reality in the average rate of interest, although the latter is not a pure or reliable expression of the former.

It is true, that the rate of interest itself differs according to the different classes of securities offered by the borrowers and according to the length of time for which the money is borrowed; but it is uniform within every one of these classes at a given moment. This distinction, then, does not militate against a fixed and uniform shape of the rate of interest.⁷²

The average rate of interest appears in every country for long epochs as a constant magnitude, because the general rate of profit — in spite of the continual variation of the particular rates of profit, in which a variation in one sphere is offset by an opposite variation in another sphere — varies only in long intervals. Its relative constancy is revealed in this more or less constant nature of the average rate, or common rate, of interest.

As concerns the continually fluctuating market rate of interest, it exists at any moment as a fixed magnitude, the same as the market price of commodities, because all the loanable capital as an aggregate mass is continually facing the invested capital, so that the relation between the supply of loanable capital on one side, and the demand for it on the other, decide at any time the market level of interest. This is so much more the case, the more the development and simultaneous concentration of the credit system impregnates the loanable capital with a general social character, and throws it all at one time on the market. On the other hand, the general rate of profit always exists as a mere tendency, as a movement to compensate specific rates of profit. The competition between capitalists — which is itself this movement toward an equilibrium — consists in this case in their activity of gradually withdrawing capital from spheres, in which the profit stays for a long time below the average, and in the same way taking capital into spheres, in which the profit is above the average. Or it may also consist in their distributing additional capital gradually and in varying

proportions between these spheres. It is always a matter of a continual variation between supply and demand of capital with reference to different spheres, never a simultaneous mass effect, as it is in the determination of the rate of interest.

We have seen that interest-bearing capital, although a category absolutely different from a commodity, becomes a peculiar commodity, so that interest becomes its price, which is fixed at any time by supply and demand, just as the market price of an ordinary commodity is fixed. The market rate of interest, while continually oscillating, appears therefore at any moment just as constantly fixed and uniform as the prevailing market price of commodities. The money-capitalists offer this commodity, and the investing capitalists buy it and make a demand for it. This does not take place in the equalisation of profits toward a general rate of profit. If the prices of commodities in a certain sphere are below or above the price of production (leaving aside any oscillations, which are found in every business and are due to fluctuations of the industrial cycles), a balance is effected by an expansion or restriction of production. This signifies an expansion or restriction of the quantities of commodities thrown on the market by industrial capitalists, by means of immigration or emigration of capital to and from particular spheres. It is by such a compensation of the average market prices of commodities to prices of production that the deviations of specific rates of profit from the general, or average, rate of profit are corrected. This process does not, and cannot, at any time assume the appearance as though the industrial or mercantile capital as such were commodities seeking a buyer, but it does in the case of interest-bearing capital. To the extent that this process is perceptible, it is so only in the oscillations and compensations of the market prices of commodities to prices of production, not in any direct fixation of the average profit. The general rate of profit is actually determined, 1), by the surplus-value produced by the capital; 2), by the proportion of this surplus-value to the value of the total capital; and, 3), by competition, but only to the extent that this is a movement, by which capitals invested in particular spheres seek to draw equal dividends out of this surplus-value in proportion to their relative magnitudes. The general rate of profit, then, derives its determination actually from causes, which are quite different and far more profound than those of the market rate of interest, which is directly and immediately determined by the proportion between supply and demand. It is, therefore,

not such a tangible and obvious fact as the rate of interest. The particular rates of interest in the different spheres of production are themselves more or less unsettled; but so far as they are perceptible, it is not their uniformity, but their differences, which appear. The general rate of profit itself appears only as the minimum limit of profit, not as the empirical and directly visible shape of the actual rate of profit.

In emphasizing this difference between the rate of interest and the rate of profit, we still leave out of consideration the following two circumstances, which favor the consolidation of the rate of interest: 1), The historical pre-existence of interest-bearing capital and the existence of a traditionally sanctioned general rate of interest; 2), the far greater direct influence exerted by the world market on the fixation of the rate of interest, independently of the economic conditions of a certain country, compared to its influence on the rate of profit.

The average profit does not appear as a directly existing fact, but merely as a final result of the compensation of opposite fluctuations, to be ascertained by analysis. Not so the rate of interest. It is, at least in its local validity, a daily fixed thing, a fact which serves even to industrial and mercantile capitals as a prerequisite and figure in their calculations. It becomes a general faculty of every sum of money of 100 pounds sterling to yield 2, 3, 4, 5%. Meteorological reports do not register the stand of the barometer and thermometer more accurately than the reports of the Bourse do the stand of the rate of interest, not for this or that capital, but for the money-capital on the market, for the available loanable capital in general.

On the money market only lenders and borrowers face one another. The commodity has the same form, money. All specific forms of capital according to its investment in particular spheres of production or circulation are here blotted out. It exists here in the undifferentiated, homogenous, form of independent value, money. The competition of the individual spheres ceases here. They are all thrown together as borrowers of money, and capital likewise faces all of them in a form, in which it is as yet indifferent to its definite investment in this or that specific manner. The character worn by industrial capital only in its movement and competition between individual spheres, the character of a common capital of a class comes into evidence here in full force by the demand and supply of capital. On the other hand, money-capital on the money market has actually that form, in which it may be distributed as a common element among the capitalists in

the various spheres, regardless of its specific employment, as the requirements of production in each individual sphere may dictate. Add to this that with the development of large scale industry money-capital, so far as it appears on the market, is not represented by some individual capitalist, not by the owner of this or that fraction of the capital on the market, but assumes more and more the character of an organised mass, which is far more directly subject to the control of the representatives of social capital, the bankers, than actual production is. Under these circumstances, not only the demand for loanable capital is expressed with the full force of a class, but also its supply appears as loanable capital in masses.

These are some of the reasons, why the general rate of profit appears as a vanishing shape of mist compared to the definite rate of interest, which, while fluctuating in its magnitude, yet faces all borrowers as a fixed fact, because it varies uniformly for all of them. In like manner the variations in the value of money do not prevent it from having the same value for all commodities. In like manner the market prices of commodities fluctuate daily, yet this does not prevent them from being reported daily. In like manner, the rate of interest is regularly reported as “the price of money.” It is so for the reason that capital itself is here offered in the form of money as a commodity. The fixation of its price is thus a fixation of its market price, as it is with all other commodities. Thus the rate of interest always appears as the general rate of interest, as so much for so much money, as a definite quantity. Not so the rate of profit. It may vary even within the same sphere for commodities with the same price, according to the different conditions under which different capitals produce the same commodity. For the rate of profit of the individual capital is determined, not by the market price of a commodity, but by the difference between the market-price and the cost-price. And these different rates of profit, first within the same sphere and then between different spheres themselves, can be balanced only by continual fluctuations.

(Note for later elaboration): A specific form of credit. It is known that when money serves as a means of payment instead of as a means of purchase, the commodity is transferred, but its value is not realised until later. If payment is not made until after the commodity has again been sold, then this sale does not seem to be the result of the purchase, but it is by this sale that the purchase is realised. In other words, the sale becomes a means of purchase. — Secondly; Titles to debts, bills of exchange, etc., become

means of payment for the creditor. — Thirdly: The compensation of titles to debts replaces the money.

CHAPTER XXIII. INTEREST AND PROFIT OF ENTERPRISE.

INTEREST, as we have seen in the two preceding chapters, seems to be originally, is originally, and remains in fact merely a portion of profit, of surplus-value, which the investing capitalist, whether industrial or commercial, has to pay over to the owner and lender of money-capital whenever he uses loan capital instead of his own. If he employs only his own capital, no such division of profit takes place; it is all his. In fact, to the extent that the owners of capital employ it themselves in the process of reproduction, they do not compete in the determination of the rate of interest. This alone shows that the category of interest, an impossibility without a determination of the rate of interest, is alien to the movements of industrial capital itself.

“The rate of interest may be defined to be that proportional sum which the lender is content to receive, and the borrower to pay, for a year or for any longer or shorter period for the use of a certain amount of moneyed capital...when the owner of capital employs it actively in reproduction, he does not come under the head of those capitalists, the proportion of whom, to the number of borrowers, determines the rate of interest.” (Th. Tooke, *History of Prices*, Newmarch ed. London, 1857, II, .) It is indeed only the separation of capitalists into money-capitalists and industrial capitalists, which transforms a portion of the profit into interest, which creates the category of interest at all; and it is only the competition between these two kinds of capitalists which creates the rate of interest.

So long as capital serves in the process of reproduction — even assuming that it belongs to the industrial capitalist himself, so that he has no need of paying it back to some lender — just so long the capitalist has at his disposal as a private individual, not this capital itself, but only the profit, which he may spend as revenue. So long as his capital performs the functions of capital, it belongs to the process of reproduction, it is tied up in that process. He is indeed its owner, but this ownership does not enable him to dispose of it in some other way, so long as he uses it as capital for the exploitation of labor. It is the same with the money-capitalist. So long as his

capital is loaned out and serves as money-capital, it brings him as interest a portion of the profit, but he cannot dispose of the principal. This becomes evident, whenever he loans his capital, say, for one year, or longer, and receives interest at certain stipulated times without recovering his principal. But even the return of the principal does not make any difference here. If he gets it back, then he must always loan it out again, so long as he expects it to produce the effects of capital, in this case of money-capital, for him. While he is keeping it in his own hands, it collects no interest, it does not act in the capacity of capital; and so long as it gathers interest and serves as capital, it is not in his hands. This accounts for the possibility to loan capital for all eternity. The following remarks of Tooke against Bosanquet are, therefore, entirely wrong. He quotes Bosanquet (Metallic, Paper, and Credit Currency,): “If the rate of interest were depressed to 1%, then borrowed capital would be almost on a par with owner’s capital.” Tooke makes the following comment on this: “That a capital borrowed at this, or even at a lower rate, should be considered as being almost on a par with one’s own capital is such a strange contention, that it would hardly deserve any serious consideration, did it not come from so intelligent a writer, who is so well informed on particular points of his subject. Has he overlooked the fact, or does he hold it to be so unimportant, that his assumption implies the condition of return payment?” (Th. Tooke, *An Inquiry into the Currency Principle*, 2nd. edition, London, 1844, .) If interest were equal to zero, then the industrial capitalist working with a borrowed capital would be on a par with a capitalist working with his own capital. Both of them would pocket the same average profit, and capital, whether borrowed or the owner’s, serves as capital only to the extent that it produces profit. The condition of return payment would not alter this in the least. The more the rate of interest approaches zero, falling, for instance, to 1%, the more borrowed capital is placed on a par with owner’s capital. So long as money-capital is expected to act in the capacity of money-capital, it must always be loaned out again and again, and this must take place at the prevailing rate of interest, say 1%, and always to the same class of industrial and commercial capitalists. So long as these perform the functions of capitalists, the only difference between one working with a borrowed and one working with his own capital is that the one has to pay interest and the other has not; that the one pockets the whole profit p , and the other only $p - i$, profit minus interest. To the extent that the interest approaches zero, $p - z$ becomes equal to p ,

and to the same extent do both capitals stand on a par. The one must pay back the capital and borrow it again; but the other, so long as his capital is expected to perform its function, must likewise advance it again and again to the process of production and cannot dispose of it freely without any dependence upon this process. The only remaining difference between the two is the obvious one that the one is the owner of his capital and the other is not.

The question which arises here is this: How is it that this purely quantitative division of profit into net profit and interest turns into a qualitative one? In other words, how is it that even the capitalist who employs only his own capital, and not a borrowed one, ranges a portion of his gross profit under the specific category of interest and calculates it separately as such? And furthermore, why is all capital, whether borrowed or not, differentiated in itself as interest-bearing capital from net profit producing capital?

It is understood that not every accidental quantitative division of profit turns in this manner into a qualitative one. For instance, some industrial capitalists associate for some business and divide the profits among themselves according to some legal agreement. Others carry on their business, each by himself, without any associate. These last do not calculate their profit under two heads, one part as individual profit, the other as profits of the company for associates who do not exist. In this case the quantitative division does not turn into a qualitative one. It takes place, when the ownership is vested accidentally in several juridical personalities. It does not take place, when this is not the case.

In order to answer this question, we must dwell a little longer on the actual point of departure of the formation of interest; that is, we must take our departure from the assumption, that the money-capitalist and the industrial capitalist really face one another, not merely as legally different persons, but as persons playing entirely different roles in the process of reproduction, or as persons in whose hands the same capital really passes through a twofold and wholly different movement. The one merely loans it, the other employs it productively.

For the productive capitalist, who works with a borrowed capital, the gross profit falls into two parts, namely into the interest to be paid by the lender and the surplus over the interest forming his own share of the profit. If the general rate of profit is given, then this last portion is determined by

the rate of interest; if the rate of interest is given, then this last portion is determined by the general rate of profit. And furthermore: Whatever may be the divergence in any individual case of the gross profit, the actual magnitude of value of the total profit, from the average profit, it does not alter the fact that the portion belonging to the investing capitalist is determined by the interest, since this is fixed by the general rate of interest (aside from special legal stipulations) and assumed to be paid beforehand, before the process of production begins, and before its result, the gross profit, has been made. We have seen that the peculiar and specific product of capital is surplus-value, or more closely defined, profit. But for the capitalist working with a borrowed capital it is not the profit, but the profit minus the interest, that portion of the profit which remains for him after the interest has been deducted. This portion of the profit necessarily appears to him as the product of a capital performing its function; and so far as he is concerned it is really so, because he is the representative of capital in action. He is its personification to the extent that it is in function, and it performs its function to the extent that it is profitably invested in industry or commerce and engaged, through its employer, in such operations as are prescribed by the line of its industry. In distinction from interest, which he has to pay out of the gross profits to the lender, the remaining portion of the profit, which he pockets, necessarily assumes the form of industrial or commercial profit, or, to designate it by a term comprising both of them, the form of profit of enterprise. If the gross profit is equal to the net profit, then the magnitude of this profit of enterprise is exclusively determined by the rate of interest. If the gross profit varies from the average profit, then its difference from the average profit (after deducting the interest from both of them) is determined by all constellations causing a temporary deviation, either of the rate of profit in any particular sphere from the general rate of profit, or of the profit made by some individual capitalist in a certain sphere from the average profit of this sphere. Now, we have seen, that the rate of profit within the process of production itself does not depend merely on the surplus-value, but also on many other circumstances, for instance, on the purchase prices of the means of production, on methods more productive than the average, on economies in constant capital, etc. And aside from the price of production, it depends on special constellations of the market, and in every business transaction on the greater or lesser smartness and thrift of the individual capitalists, whether, and to what

extent, a man will buy or sell above or below the price of production and thus appropriate in the process of circulation a greater or smaller portion of the total surplus-value. At any rate the quantitative division of the gross profit turns here into a qualitative one, and it does so all the more as the quantitative division itself depends on the nature of thing that is to be divided, on the manner in which the capitalist manages his capital, and on the amount of gross profit it yields for him in his capacity as active capitalist. The investing capitalist is here assumed not to be the owner of the capital. The ownership of capital is vested in the money-capitalist, who stands opposed to him. The interest, which he pays to the lender, thus appears as that portion of the gross profit, which is absorbed by the ownership of capital as such. In distinction therefrom, that portion of the profit, which falls to the share of the investing capitalist, appears then as profit of enterprise, arising solely from the operations, or functions, which he performs with the capital in the process of reproduction, particularly of those functions, which he performs as the impersonator of enterprise in industry or commerce. From his point of view, the interest appears merely as the fruit of the ownership of capital, of capital “itself” abstracted from the process of capital in reproduction, of a capital not “working,” not performing its function; while profit of enterprise appears to him as the exclusive fruit of the functions, which he performs with the capital, a fruit of the movements and performances of capital, of performances, which appear to him as his own activity as differentiated from the inactivity, the non-participation, of the money-capitalist in the process of production. This qualitative separation of the two portions of gross profit, which makes interest appear as the fruit of abstract capital, of the ownership of capital outside of the process of production, and profit of enterprise as the fruit of capital performing its function in the process of production, of the active role played by the employer of capital in the process of reproduction, this qualitative separation is by no means merely a subjective point of view of the money-capitalist on one side and of the industrial capitalist on the other. It rests upon an objective fact, for the interest flows into the hands of the money-capitalist, the lender, the mere owner of capital, who represents only capital property before the process of production and outside of it; while the profit of enterprise flows only into the hands of the investing capitalist, who is not the owner of the capital.

In this way, both the industrial capitalist working with borrowed capital and the money-capitalist not working himself with his capital play a role, in which a merely quantitative division of the gross profit between two persons having two different legal titles to the same capital and to the profit produced by it turns into a qualitative division. One portion of the profit appears now as interest, as a fruit coming to capital in one of its forms; the other portion appears as a specific fruit of capital in an opposite form, and thus as profit of enterprise. One appears as the fruit of mere ownership of capital, the other as a fruit of the performance of the function of capital, as a fruit of capital in process, of the functions performed by the active capitalist. And this ossification and individualisation of the two parts of the gross profits among themselves, as though they were derived from two essentially different sources, now becomes a fixture for the entire capitalist class and the total capital. And this takes place regardless of whether the capital employed by the active capitalist is borrowed or not, and whether the capital belonging to the money-capitalist is employed by himself or not. The profit of every capital, and consequently the average profit established by a mutual compensation of capitals, is separated into two qualitatively different, separately individualised, and mutually independent parts, to wit, interest and profit of enterprise, both of which are determined by particular laws. The capitalist working with his own capital divides the gross profit into interest due to himself as its owner lending it to himself, and into profit of enterprise due to himself as an active capitalist performing his function, just as does the capitalist working with a borrowed capital. For this division, in its qualitative aspects, it becomes immaterial whether the capitalist really has to divide his profit with another or not. The employer of capital, even when working with his own capital, falls apart into two personalities, into the mere owner of capital and the employer of capital; his capital itself, with reference to the categories of profit which it yields, falls apart into capital property outside of the process of production and yielding interest of itself, and capital in the process of production yielding profit of enterprise through its function in the process.

Interest, then, becomes so firmly established, that it no longer appears as a division of gross profits, to which production is indifferent and which takes place only occasionally when the industrial capitalist works with the capital of some other man. Even when he works with his own capital, his profit is separated into interest and profit of enterprise. Thus a merely

quantitative division turns into a qualitative one. It takes place without regard to the fact, whether the industrial capitalist is, or is not, the owner of the capital employed by him. It is no longer a question of different quota of profit assigned to different persons, but of two different categories of profit holding different relations to the capital, being related to different forms of capital.

It is a simple matter, in view of the foregoing remarks, to explain, why this character of qualitative separation becomes established for the total social capital and the entire capitalist class, as soon as the separation of gross profits into interest and profits of enterprise has assumed its qualitative aspect.

This follows from the simple empirical circumstance, that the majority of the industrial capitalists, even if in different proportional numbers, work with their own and with borrowed capital, and that the proportion between self-owned and borrowed capital changes in different periods.

The transformation of a portion of the gross profits into the shape of interest converts the other portion into profit of enterprise. The latter is indeed but the antagonistic form assumed by the excess of the gross profit over the interest, as soon as interest exists as an independent category. The entire analysis of the problem, how gross profit is differentiated into interest and profit of enterprise, resolves itself into the inquiry, how a portion of the gross profits becomes universally ossified and individualised in the shape of interest. Now, historically, interest-bearing capital exists as a complete, traditional form, and with it interest as a ready subdivision of the surplus-value produced by capital, long before the capitalist mode of production and the conceptions of capital and profit belonging to it existed. Thus it is that popular conception still regards money-capital, interest-bearing capital, as typical capital, as capital par excellence. Thus, also, we find up to the time of Massie the prevailing idea, that it is money as such, which is paid in interest. The fact that loaned capital yields interest, whether it is actually employed as interest or not — even when borrowed only for consumption — lends strength to the idea of the independence of this form of capital. The best proof of the independence, which interest seemed to have with reference to profit and interest-bearing capital with reference to industrial capital, during the first periods of the capitalist mode of production, is that it was not until the middle of the 18th century that Massie, and after him

Hume, discovered the fact that interest is but a portion of the gross profit, and that such a discovery was necessary at all.

Whether the industrial capitalist works with his own or with borrowed capital, it does not alter the fact that the class of money-capitalists face him as a special class of capitalists, money-capital as an independent form of capital, and interest as the independent form of surplus-value peculiar to this specific capital.

Qualitatively speaking, interest is surplus-value supplied by the mere ownership of capital, yielded by capital as such, even though its owner remains outside of the process of reproduction. It is surplus-value realised by capital outside of its process.

Quantitatively speaking, that portion of profit, which forms interest, does not seem to be related to industrial or commercial capital as such, but to money-capital, and the rate of this portion of surplus-value, the rate of interest, fortifies this relation. For, in the first place, the rate of interest, despite its dependence upon the general rate of profit, is independently determined, and, in the second place, it appears with all its variations as a fixed, uniform, tangible and always given relation, just like the market-prices of commodities, compared to the intangible rate of profit. If all capital were in the hands of the industrial capitalists, there would be no interest and no rate of interest. The independent form assumed by the quantitative division of gross profit creates the qualitative one. If the industrial capitalist compares himself to the money-capitalist, only his profit of enterprise distinguishes him from the other man, the excess of his gross profit over the average interest, the latter being empirically given by means of the rate of interest. On the other hand, if he compares himself to the industrial capitalist working with his own, instead of borrowed capital, the other differs from him only as a money-capitalist by pocketing the interest instead of paying it over to some one else. On either side the portion of the gross profit differing from the interest appears to him as profit of enterprise, and interest itself as a surplus-value yielded by capital as such, which it would yield even without any productive employment.

This is practically correct for the individual capitalist. He has the choice, whether he wants to invest his capital as an interest-bearing one or as a productive one, regardless of whether it exists in the form of money-capital from the out-set, or whether it has to be converted into money-capital. But

to make this conception a general one and apply it to the total capital of society, as some vulgar economists do, who even go so far as to regard this capital as the source of profit, is, of course, preposterous. The idea of a conversion of the total capital of society into money-capital without the existence of people, who shall buy and utilise the means of production, which form the total capital with the exception of relatively small portion existing in the shape of money, is sheer nonsense. It implies the additional nonsense, that capital could yield interest on the basis of capitalist production without performing any productive function, in other words, without producing any surplus-value, of which interest would be but a part; that the capitalist mode of production could run its course without any capitalist production. If an excessively large number of capitalists were to convert their capital into money-capital, it would result in an extraordinary depreciation of money-capital and an extraordinary fall of the rate of interest; many would at once be face to face with the impossibility of living on their interest, and would be compelled to retransform themselves into industrial capitalists. But we repeat that it is a fact for the individual capitalist. For this reason, he necessarily considers that part of his average profit, which is equal to the average interest, as a fruit of his capital as such, apart from the process of production, even when he works with his own capital; and he differentiates from this portion, from this interest, that surplus of the gross profit, which constitutes his profit of enterprise.

(A blank in the manuscript.)

We have seen that that portion of the profit, which the investing capitalist has to pay to the mere owner of borrowed capital, converts itself into the independent form of a portion of profit, which all capital as such, whether borrowed or not, yields under the name of interest. How large that portion shall be is determined by the quotation of the average rate of interest. Its origin does not show itself any more in anything but the fact that the investing capitalist, when owner of his capital, no longer competes in the determination of the rate of interest, at least not actively. The purely quantitative division of profit between two persons having different legal titles to it has turned into a qualitative division, which seems to arise from the nature of capital and profit itself. For, as we have seen, as soon as a portion of the profit generally assumes the form of interest, the difference between the average profit and the interest, or the portion of profit exceeding the interest, assumes a form antagonistic to interest, that of profit

of enterprise. These two forms, interest and profit of enterprise, exist only as opposites. They are not reduced to the surplus-value, of which they represent proportional parts cast in different moulds, but are merely referred to one another. Because one portion converts itself into interest, the other portion appears as profit of enterprise.

By profit we always mean average profit here, since the variations of individual profit and of profit in different spheres, due to the fluctuations of the competitive struggle and other circumstances affecting the distribution of the average profit, or surplus-value, do not concern us in this analysis. This applies quite generally to the foregoing inquiry.

Interest is then net profit, as Ramsay calls it, which capital as such yields, either for the mere lender remaining outside of the process of reproduction, or for the owner employing his capital productively. For this latter capitalist also, capital yields this net profit, not in his capacity as a productive capitalist, but of money-capitalist and lender of his own capital as an interest-bearing one to himself as an investing capitalist. Just as the conversion of money, and of value in general, into capital is the constant result of capitalist production, so its existence in the form of capital is its constant prerequisite. By its ability to transform itself into means of production, it commands continually unpaid labor and thereby transforms the process of production and circulation of commodities into a production of surplus-value for its owner. Interest is, therefore, merely the expression of the fact, that value in general, in other words, value representing materialised labor in its general social form, or value assuming the form of means of production in the actual process of production, faces living labor-power as an independent power, and is a means of appropriating unpaid labor; and that it is such a power, because it represents the property of another in opposition to the laborer. But on the other hand, this opposition to wage-labor is obliterated in the form of interest; for interest-bearing capital as such has not wage-labor, but productive capital for its object. The lending capitalist faces as such the capitalist performing his actual function in the process of reproduction, not the wage-worker, who is expropriated from the means of production under capitalist production. Interest-bearing capital represents capital as ownership compared to capital as a function. But to the extent that capital does not perform its function, it does not exploit the laborers and does not come into opposition to labor.

On the other hand, profit of enterprise is not in opposition to wage-labor, but only to interest.

Assuming the average profit to be given, the rate of profit on enterprise is not determined by wages, but by the rate of interest. It is high or low inversely as the rate of interest is.⁷³

The investing capitalist derives his claim to profits of enterprise, and consequently the profit of enterprise itself, not from his ownership of capital, but from its production function as distinguished from the form, in which it is only inert property. This appears as an obviously existing contrast, whenever he is working with a borrowed capital, so that interest and profits of enterprise each go to different persons. The profit of enterprise arises from the function of capital in the process of reproduction, it is a result of the operations by which the investing capitalist promotes this function of industrial and commercial capital. But to be a representative of invested capital is not a sinecure like the representation of interest-bearing capital. On the basis of capitalist production, the capitalist directs the processes of production and circulation. The exploitation of productive labor requires exertion, whether he performs it himself or has it performed by some one else in his name. In distinction from interest, his profit of enterprise appears to him as independent of the ownership of capital, it seems to be the result of his function as a non-proprietor — a laborer.

Under these circumstances his brain necessarily conceives the idea, that his profit of enterprise, far from being in opposition to wage-labor and representing only the unpaid labor of others, is rather itself wages of labor, wages of superintendence of labor. These wages are superior to those of the common laborer, 1) because they pay for more complicated labor, 2) because the capitalist pays them to himself. The fact that his function as a capitalist consists in creating surplus-value, which is unpaid labor, and to create it under the most economical conditions, is entirely forgotten over the contrast, that the interest falls to the share of the capitalist, even if he does not perform any capitalist function and is merely the owner of capital; and that, on the other hand, the profit of enterprise falls to the share of the investing capitalist, even if he is not the owner of the capital, which he employs. The antagonistic form of the two parts, into which profit, or surplus-value is divided, leads him to forget, that both parts are surplus-value, and that this division does not alter the nature, origin, and living conditions of surplus-value.

In the process of reproduction, the investing capitalist represents capital as the property of another in opposition to the wage-laborers, and the money-capitalist, represented by the investing capitalist, shares in the exploitation of labor. The fact, that the investing capitalist can perform his function or employ means of production as capital only as the personification of the means of production in opposition to the laborers, is forgotten over the antagonism between the function of capital in the process of reproduction and the mere ownership of capital outside of the process of reproduction.

In fact, the forms assumed by the two parts of profit, of surplus-value, when divided into interest and profit of enterprise, do not express their relation to labor, because their relation refers only to themselves and to the profit, or rather to the surplus-value as a whole compared to them as parts of this unit. The proportion in which the profit is divided, and the different legal titles, by which this division is sanctioned, are based on the assumption that profit is already in existence. If, therefore, the capitalist is the owner of the capital, which he employs, he pockets the whole profit, or surplus-value. It is immaterial to the laborer, whether the capitalist pockets the whole profit, or whether he has to pay over a part of it to some other person, who has a legal claim to it. The reasons for dividing the profit among two kinds of capitalists thus turn surreptitiously into reasons for the existence of the surplus-value to be divided, which the capital as such draws out of the process of reproduction quite apart from any subsequent division. Seeing that the interest is opposed to the profit of enterprise, and the profit of enterprise to the interest, that they are both opposed to one another, but not to labor, it follows that both profit of enterprise plus interest, in other words, the total profit, and further the surplus-value, are derived — from what? From the antagonistic form of its two parts! But the profit is produced, before this division takes place, and before there can be any mention of it.

Interest-bearing capital stands the test of such only to the extent that borrowed money is actually converted into capital, and that a surplus is produced with it, of which the interest is a part. But this does not militate against the fact, that the faculty of drawing interest is innate in it outside of the process of production. So does labor-power evince its faculty of producing value only so long as it is employed and materialised in the labor-process; yet this does not argue against the fact, that labor-power is

potentially a faculty of creating values, which does not arise out of the mere process of production, but is rather antecedent to it. As a faculty creating value, it is bought. One might also buy it without setting it to work productively. It may be used for purely personal ends, for instance, for personal service, etc. So it is with capital. It is the borrower's affair, whether he employs it as capital, actually setting in motion its inherent faculty of producing surplus-value. What he pays, is in either case the surplus-value inherently latent in the commodity capital.

Let us now consider profit of enterprise more in detail.

Since the specific social faculty of capital under capitalist production, that of being property in the hands of one and yet commanding the labor-power of another, becomes fixed, so that interest appears as a part of the surplus-value produced by capital in this interrelation, the other part of the surplus-value, the profit of enterprise, must necessarily appear as derived, not from capital as such, but from the process of production, separated from its social faculty, which is already expressed as a distinct mode of existence by the term interest in capital. Now, separated from capital, the process of production is simply a labor-process. Hence the industrial capitalist as differentiated from the owner of capital does not appear, in this case, as a functionary of capital, but as a functionary separated from capital, as a simple agent of the labor-process, as a laborer, and specifically as a wage-laborer.

Interest itself expresses precisely the existence of the conditions of labor in the form of capital, in their social antagonism to labor, and in their transformation into personal powers in opposition to labor and dominating it. Interest represents the mere ownership of capital as a means of appropriating the products of the labor of others. But it represents this character of capital as something, which belongs to it outside of the process of production, and which is not by any means a result of the specifically capitalist nature of this process of production itself. Interest places this process in such a light, that it does not seem opposed to labor, but rather without any relation to labor and simply the relation of one capitalist toward another. It thus assumes a form which places it outside of the relation of capital toward labor, and renders it indifferent toward this relation. In interest, then, which is that specific form of profit, in which the antagonistic character of capital assumes an independent form, this is done in such a way, that the antagonism here appears completely obliterated and left out

of consideration. Interest is a relation between two capitalists, not between a capitalist and a laborer.

On the other hand, this form of interest bestows upon the other portion of profit the qualitative form of profit of enterprise, and, further on, of wages of superintendence. The specific functions, which the capitalist as such has to perform, and which precisely differentiate him from the laborer and bring him into opposition to the laborer, are presented as mere functions of labor. He creates surplus-value, not because he performs the work of a capitalist, but because he also works aside from his capacity as a capitalist. This portion of surplus-value is thus no longer surplus-value, but its opposite, an equivalent for labor performed. Owing to the fact that the estranged character of capital, its antagonism to labor, has been relegated to a place outside of the actual process of exploitation, namely to the interest-bearing capital, this process of exploitation itself appears as a simple labor process, in which the exploiting capitalist performs merely a different kind of labor than the laborer. In this way the labor of exploitation and the exploited labor both appear as labor, as identical. The labor of exploitation is labor just as well as the labor which is exploited. It is the interest which represents the social form of capital, but it does so in a neutral and indifferent way. It is the profit of enterprise which represents the economic function of capital, but it does so in a way, which takes no cognizance of the definite capitalist character of this function.

In the present case, what passes in the consciousness of the capitalist is quite similar to what passes in the case of the fluctuations for which the capitalist makes allowance in the equalisation of the average profits, as indicated in part II of this volume. These compensating causes, which exert a determining influence on the distribution of the surplus-value, are distorted by the capitalist conception into originating causes and subjective justifications of profit itself.

The conception of profit of enterprise in the shape of wages of superintendence of labor, arising from the antagonism of profit of enterprise to interest, is further strengthened by the fact, that a portion of the profit may indeed be separated, and is separated in reality, as wages, or rather the reverse, that a portion of the wages appear under capitalist production as a separate portion of the profit. Already Adam Smith indicated, that this portion assumes its pure form, independently of profit and wholly separated from it (as the sum of interest and profit of

enterprise), and likewise separated from that portion of the profit, which remains in the shape of profit of enterprise after the deduction of the interest, in the salary of the superintendent in those lines of business, whose size, etc., permits a sufficient division of labor to justify a special salary for the labor of a superintendent.

The labor of superintendence and management will naturally be required whenever the direct process of production assumes the form of a combined social process, and does not rest on the isolated labor of independent producers.⁷⁴ It has, however, a double nature.

On one side, all labors, in which many individuals cooperate, necessarily require for the connection and unity of the process one commanding will, and this performs a function, which does not refer to fragmentary operations, but to the combined labor of the workshop, in the same way as does that of a director of an orchestra. This is a kind of productive labor, which must be performed in every mode of production requiring a combination of labors.

On the other side, quite apart from any commercial department, this labor of superintendence necessarily arises in all modes of production, which are based on the antagonism between the laborer as a direct producer and the owner of the means of production. To the extent that this antagonism becomes pronounced, the role played by superintendence increases in importance. Hence it reaches its maximum in the slave system.⁷⁵ But it is indispensable also under the capitalist mode of production since then the process of production is at the same time the process by which the capitalist consumes the labor-power of the laborer. In like manner, the labor of superintendence and universal interference by the government in despotic states comprises both the performance of the common operations arising from the nature of all communities and the specific functions arising from the antagonism between the government and the mass of the people.

In the works of ancient writers, who have the slave system under their eyes, both sides of the labor of superintendence are as inseparably combined in theory as they were in practice. So it is also in the works of the modern economists, who regard the capitalist mode of production as the absolute mode of production. On the other hand, as I shall show immediately by an example, the apologists of the modern slave system

utilise the labor of superintendence quite as much to justify slavery, as the other economists do to justify the wage system.

The villicus in Cato's time: "At the head of the rural slave community (*familia rustica*) stood the manager (*villicus*, derived from *villa*), who took receipts and made expenditures, bought and sold, received instructions from the master, gave orders and meted out punishment in his absence....The manager occupied naturally a freer position than the other slaves; the Magonian books advise to permit him to marry, raise children, and have his own funds, and Cato recommends that he be married with the female manager; he alone probably had any prospects of being liberated by the master for good behavior. For the rest, all of them formed one common economy....Every slave, including the manager himself, was supplied with his necessities at the expense of his master, in definite periods according to fixed rates, and he had to get along on that. The quantity varied according to labor, and for this reason the manager, whose work was lighter than that of the other slaves, received a smaller ration than the others." (Mommsen, *Römische Geschichte*, second edition, 1856, I, -810.)

Aristotle: "For the master proves himself such not in the buying, but in the employing of slaves." (The capitalist proves himself such, not by the ownership of capital, which gives him the power to buy labor-power, but in the employment of laborers, nowadays of wage laborers in the process of production.) "But there is nothing great about this knowledge. For whatever the slave must be able to perform, the master must be able to order. Whenever the masters are not compelled to drudge at superintendence, the manager assumes this honor, while the masters attend to affairs of state or study philosophy." (Aristotle, *Republic*, Bekker edition, Book I, 7.)

Aristotle says in plain words, that rulership on the political and economic field imposes upon the powers that be the functions of government, and that they must understand the art of consuming labor-power. And he adds, that this labor of superintendence is not a matter of great moment, and that for this reason the master, who is wealthy enough, leaves the "honor" of this drudgery to an overseer.

The labor of management and superintendence arising out of the servitude of the direct producers has often been quoted in justification of this relation, not because it is a function due to the nature of all combined social labor, but because it is due to the antagonism between the owner of

means of production and the owner of mere labor-power, regardless of whether this labor-power is bought by buying the laborer himself, as it is under the slave system, or whether the laborer himself sells his labor-power, so that the process of production is the process by which capital consumes his labor-power. And exploitation, the appropriation of the unpaid labor of others, has quite as often been represented as the reward justly due to the owner of capital for his labor. But it was never better defended than it was by a champion of slavery in the United States, a certain lawyer O'Connor, at a meeting held in New York, on December 19th, 1859, under the slogan of "Justice for the South." "Now, Gentlemen," he said amid great applause, "nature itself has assigned this condition of servitude to the negro. He has the strength and is fit to work; but nature, which gave him this strength, denied him both the intelligence to rule and the will to work. (Applause.) Both are denied to him! And the same nature, which denied him the will to work, gave him a master, who should enforce this will, and make a useful servant of him in a climate, to which he is well adapted, for his own benefit and that of the master who rules him. I assert that it is no injustice to leave the negro in the position, into which nature placed him; to put a master over him; and he is not robbed of any right, if he is compelled to labor in return for this, and to supply a just compensation for his master in return for the labor and the talents devoted to ruling him and to making him useful to himself and to society."

Now, the wage-laborer, like the slave, must have a master, who shall put him to work and rule him. And assuming this relation of master and servant to exist, it is quite proper to compel the wage-laborer to produce his own wages and also the wages of superintendence, a compensation for the labor of ruling and superintending him, "a just compensation for his master in return for the labor and talents devoted to ruling him and to making him useful to himself and to society."

The labor of superintendence and management arising out of the antagonistic character and rule of capital over labor, which all modes of production based on class antagonisms have in common with the capitalist mode, is directly and inseparably connected, also under the capitalist system, with those productive functions, which all combined social labor assigns to individuals as their special tasks. The wages of an epitropos, or régisseur, as he used to be called in feudal France, are entirely differentiated from the profit and assumes the form of wages for skilled labor, whenever

the business is operated on a sufficiently large scale to warrant paying such a manager, although our industrial capitalists do not “attend to affairs of state or study philosophy” for all that.

That not the industrial capitalists, but the industrial managers are “the soul of our industrial system,” has already been remarked by Mr. Ure.⁷⁶ So far as the commercial part of the business is concerned, we have said as much as was necessary in the preceding part of this volume.

The capitalist mode of production itself has brought matters to such a point, that the labor of superintendence, entirely separated from the ownership of capital, walks the streets. It is, therefore, no longer necessary for the capitalist performs the labor of superintendence himself. A director of an orchestra need not be the owner of the instruments of its members, nor is it a part of his function as a director, that he should have anything to do with the wages of the other musicians. The co-operative factories furnish the proof, that the capitalist has become just as superfluous as a functionary in production as he himself, in his highest developed form, finds the great real estate owner superfluous. To the extent that the labor of the capitalist is not the purely capitalistic one arising from the process of production and ceasing with capital itself, to the extent that it is not limited to the function of exploiting the labor of others, to the extent that it rather arises from the social form of the labor-process as a combination and co-operation of many for the purpose of bringing about a common result, to that extent it is just as independent of capital as that form itself, as soon as it has burst its capitalistic shell. To say that this labor as a capitalistic one, as a function of the capitalist is necessary, amounts merely to saying that the vulgar economist cannot conceive of the forms developed in the womb of capitalist production separated and freed from their antagonistic capitalist character. Compared to the money-capitalist the industrial capitalist is a laborer, but a laboring capitalist, an exploiter of the labor of others. The wages which he claims and pockets for this labor amount exactly to the appropriated quantity of another’s labor and depend directly upon the rate of exploitation of this labor, so far as he takes the trouble to assume the necessary burdens of exploitation. They do not depend upon the degree of his exertions in carrying on this exploitation. He can easily shift this burden to the shoulders of a superintendent for moderate pay. After every crisis one may see plenty of ex-manufacturers in the English factory districts, who for low wages

superintend their own former factories as managers of the new owners, who are frequently their creditors.⁷⁷

The wages of superintendence, both for the commercial and the industrial manager, appear completely separated from the profits of enterprise in the co-operative factories of the laborers as well as in capitalistic stock companies. The separation of the wages of superintendence from the profits of enterprise, which is at other times accidental, is here constant. In the co-operative factory the antagonistic character of the labor of superintendence disappears, since the manager is paid by the laborers instead of representing capital against them. Stock companies in general, developed with the credit system, have a tendency to separate this labor of management as a function more and more from the ownership of capital, whether it be self-owned or borrowed. In the same way the development of bourgeois society separates the functions of judges and administrators from feudal property, whose prerogatives they were in feudal times. Since the mere owner of capital, the money-capitalist, has to face the investing capitalist, while money-capital itself assumes a social character with the advance of credit, being concentrated in banks and loaned by them instead of by its original owners, and since, on the other hand, the mere manager, who has no title whatever to the capital, whether by borrowing or otherwise, performs all real functions pertaining to the investing capitalist as such, only the functionary remains and the capitalist disappears from the process of production as a superfluous person.

From the public accounts of the co-operative factories in England⁷⁸ it is manifest, that the profit, after the deduction of the wages of the superintendent, which form a part of the invested capital the same as the wages of the other laborers, was higher than the average profit, although they paid occasionally a much higher interest than the private factories. The cause of the greater profit was in all these cases a greater economy in the use of constant capital. What interests us particularly here is the fact that here the average profit (= interest + profit of enterprise) presents itself actually and palpably as a magnitude, which is wholly separated from the wages of superintendence. Since the profit was here higher than the average profit, the profit of enterprise was also higher than the current one.

The same fact is revealed by some capitalist stock companies, such as joint stock banks. The London and Westminster Bank paid in 1863 annual dividends of 30%, the Union Bank of London and others 15%. Aside from

the salary of the director, the interest paid for deposits is here deducted from the gross profit. The high profit is explained in this case by the small proportion of the paid-up capital to the deposits. For instance, in the case of the London and Westminster Bank, it was in 1863: Paid-up Capital 1,000,000 pounds sterling; deposits 14,540,275 pounds sterling. In that of the Union Bank of London, 1863: Paid-up capital 600,000 pounds sterling; deposits 12,384,173 pounds sterling.

The confounding of the profit of enterprise with the wages of superintendence or management was due originally to the antagonistic form assumed toward interest by the surplus over the interest. It was further promoted by the apologetic intention to represent profit, not as a surplus-value derived from unpaid labor, but as wages of the capitalist himself for labor performed by him. This was met on the part of the socialists by the demand, that profit should actually be reduced to what it pretended to be theoretically, namely mere wages of superintendence. And this demand was all the more disagreeable to the apologists of the capitalists, as these wages of superintendence, like all other wages, found on one hand their level and fixed market-price to the extent that a numerous class of industrial and commercial superintendents was formed,⁷⁹ while on the other hand these wages fell, like all wages for skilled labor, with the general development, which reduces the cost of production of specifically trained labor-power.⁸⁰ With the development of co-operation on the part of the laborers, of stock enterprises on the part of the bourgeoisie, even the last pretext for the confusion in matters of profit of enterprise and wages of management was removed, and profit appeared also in practice what it was undeniably in theory, mere surplus-value, a value for which no equivalent was paid, realised unpaid labor. It was then seen that the investing capitalist really exploits labor, and that the fruit of his exploitation, when he worked with a borrowed capital, was divided into interest and profit of enterprise, a surplus of profit over interest.

On the basis of capitalist production, a new swindle develops in stock enterprises with the wages of management. It consists in placing above the actual director a board of managers or directors, for whom superintendence and management serve in reality only as a pretext for plundering stockholders and amassing wealth. Very interesting details concerning this are found in "The City or the Physiology of London Business; with Sketches on 'Change, and the Coffee Houses, London. 1845." Here is a

sample: “What bankers and merchants gain by being on the boards of eight or nine different companies, may be seen from the following illustration: The private account of Mr. Timothy Abraham Curtis, handed in by the court of bankruptcy on his failure, showed an income of 8,900 pounds sterling per year under the head of directorships. Since Mr. Curtis had been a director of the Bank of England and of the East Indian Company, every stock company was happy to secure him as a director.” (P. 82.) — The remuneration of the directors of such companies for each weekly meeting is at least one guinea. The proceedings of the court of bankruptcy show, that these wages of superintendence are as a rule inversely proportioned to the actual superintendence performed by these nominal directors.

CHAPTER XXIV. EXTERNALISATION OF THE RELATIONS OF CAPITAL IN THE FORM OF INTEREST-BEARING CAPITAL.

IN the interest-bearing capital, the relations of capital assume their most externalised and most fetish-like form. We have here $M — M'$ money creating more money, self-expanding value, without the process intermediate between these two extremes. In the merchants' capital, $M — C — M'$, there is at least the general form of the capitalistic process, although it clings to the sphere of circulation, so that profit appears merely as profit from selling; but it is at least seen to be the product of a social relation, not the product of a mere thing. The form of merchants' capital presents at least the aspect of a process, of a unity of antagonistic phases, of a movement divided into two transactions, namely into the purchase and sale of commodities. This is obliterated in $M — M'$, the form of interest-bearing capital. For instance, if 1,000 pounds sterling are loaned by some capitalist, when the rate of interest is 5%, then the value of 1,000 pounds sterling as a capital for one year is $C + Ci'$, C standing for the capital and i' for the rate of interest. In the present case this would mean 5%, or $5/100$ or $1/20$, and $1,000 + 1,000 \text{ times } 1/20 = 1,050$ pounds sterling. The value of 1,000 pounds sterling as capital is 1,050 pounds sterling, that is, capital is not a simple magnitude. It is a relation of magnitudes, a relation of principal sum, as a given value, to itself as a self-expanding value, as a principal sum having produced a surplus-value. And we have seen that capital assumes this form of a directly self-expanding value for all investing capitalists, whether they work with their own or with a borrowed capital.

$M — M'$. We have here the original starting point of capital, we have money in the formula $M — C — M'$ reduced to its two extremes $M — M'$, in which M' stands for $M + \text{increment of } M$, money creating more money. It is the primal and general formula of capital concentrated into a meaningless summary. It is capital perfected, a unity of the process of production and process of circulation, yielding a certain surplus-value in a certain period of time. In the form of interest-bearing capital this appears spontaneously without any intervention of the processes of production and circulation. Capital appears as a mysterious and self-creating source of interest, a thing

increasing itself. The Thing (money, commodity, value) is now capital even as a mere thing, and capital appears as a mere thing. The result of the entire process of reproduction appears as a faculty inherent in the thing itself. It depends on the owner of the money, which represents the universal exchange-form of commodities, whether he wants to spend it as money or loan it as capital. In the interest-bearing capital, therefore, this automatic fetish is elaborated in its pure state, it is self-expanding value, money generating money, and in this form it does not carry any more scars of its origin. The social relation is perfected into the relation of a thing, of money, to itself. Instead of the actual transformation of money into capital, only an empty form meets us here. As in the case of labor-power, so here in the case of interest-bearing capital the use-value of money becomes that of creating value, and at that a greater value than it contains itself. Money as such is potentially self-expanding value and is loaned as such, and loaning is the form of sale for this peculiar commodity. It becomes a faculty of money to generate value and yield interest, just as it is a faculty of a pear tree to bear pears. And the money lender sells his money as such an interest-bearing thing. But that is not all. The actually invested capital, as we have seen, presents itself in such a light, that it seems to yield the interest, not as a capital performing its function, but as a capital in itself, as money-capital.

And still something else becomes perverted. While interest is only a portion of the profit, that is, of surplus-value, which the investing capitalist squeezes out of the laborer, it looks now on the contrary as though the interest were the typical fruit of capital, the primal thing, and profit, in the shape of profit of enterprise, a mere accessory and by-product of the process of reproduction. Thus the fetish form of capital and the conception of a fetish capital are perfect. In $M - M'$ we have the void form of capital, the perversion and individualisation of the relations of production in their highest degree. The interest-bearing form is the simple form of capital, in which it is assumed to be antecedent to its own process of reproduction. It is the faculty of money, or of a commodity, to expand its own value independently of reproduction, a mystification of capital in its most flagrant form.

For vulgar political economy, which desires to represent capital as a spontaneous source of value and its creation, this mystic form is, of course, a great boon. It is a form, in which the source of profit is no longer

discernible, and in which the result of the capitalist process of production receives an independent existence apart from this process.

It is not until capital becomes money-capital, that it can assume the form of a commodity, whose self-expanding faculty has a definite price, which is quoted in the current rate of interest.

As an interest-bearing capital, in its direct form of interest-bearing money-capital (the other forms of interest-bearing capital, which do not concern us here, are derived from this one and require its existence), capital assumes its pure fetish form, $M - M'$ as a subject and a saleable thing. In the first place, its continual existence as money gives to it a form, in which all its functions are obliterated and its real elements invisible. For money is precisely that form, in which the distinctions of commodities as use-values are concealed, and with them the distinctions of the industrial capital consisting of these commodities and their conditions of production. It is that form, in which value, in the present case capital, exists as an independent exchange-value. In the process of reproduction of capital, the money-form is but a transient one, a mere passing link. But on the money-market, capital always exists in this form. In the second place, the surplus-value produced by it, which has here again the form of money, appears as inherent in it. Like the growing of trees, so the breeding of money appears as an innate quality of capital in the form of money-capital.

In the interest-bearing capital, the movement of capital is contracted. The intervening process is omitted. In this way a capital of 1,000 appears with the fixed faculty of being of itself 1,100 and converting itself after a certain period into 1,100, just as wine in a cellar improves its use-value after a certain period. Capital is then a thing, which is of itself capital. The money is then pregnant. As soon as it has been loaned, or invested in the process of reproduction (when it yields interest to its owner separate from profit of enterprise for his function as investing capitalist), the interest accumulates, whether it be awake or asleep, at home or abroad, day or night. In the interest-bearing money capital, then, the fervent wish of the hoarding miser is fulfilled (and all capital is money-capital, so far as the expression of its value is concerned, or is considered as the expression of money-capital).

It is this inherent dwelling of interest in money-capital as a thing (and this is the aspect here assumed by the production of surplus-value by capital), which engages Luther's attention so much in his naive thundering against usury. After demonstrating, that interest may be demanded, when

failure to pay back a loan to a lender, who has to meet a certain payment himself, caused a loss to him, or when he might have made a profit on a bargain, for instance in buying a garden, but lost it for the reason that the borrower failed to return the loan on time, Luther continues: “Now that I have loaned you 100 guilders, you make good my double loss due to the fact that I could not pay on one side and not buy on the other, so that I had to lose on both sides, and this is called double interest, for loss sustained and gain stopped....Having heard that John lost on his loan of 100 guilders and demands just damages, they rush in and charge double interest on every 100 guilders, which interest was only charged for the loss due to nonpayment and to inability to make a profit on a bargain, just as though every 100 guilders could naturally grow double interest, so that whenever they have 100 guilders, they loan them out and charge for two losses, which they have not at all sustained....Therefore you are a usurer, who takes damages out of his neighbor’s money for an imaginary loss that you did not sustain at all, and which you can neither prove nor calculate. This sort of loss is called by the jurists not true, but fantastical interest. It is a loss of which each dreams for himself....It will not do to say that you might incur a loss, because I might not have been able to pay or buy. That would be making something out of a thing that is not so, a thing that is uncertain into a thing that is absolutely sure. Such usury would eat up the world in a few years....If the lender accidentally incurs a loss, without his fault, he may demand damages for it, but it is different in trade and just the reverse. There they scheme to profit at the expense of their needy neighbors, how to amass wealth and get rich, to be lazy and idle and live in luxury on the labor of others, without any care, danger and loss. To sit behind the stove and let my 100 guilders gather wealth for me in the country and yet keep them in my pocket, because they are only loaned, without any danger or risk, my friend, who would not like to do that!” (Martin Luther, *An die Pfarherrn wider den Wucher zu predigen*, etc., Wittenberg, 1540.)

The idea of capital as a self-reproducing and thereby self-expanding value, lasting and growing eternally by virtue of its inherent power — by virtue of the hidden faculties of the scholastics — has led to the fabulous fancies of Dr. Price, which far outdo the fantasies of the alchemists; fancies, in which Pitt seriously believed and which he used as pillars of his financial administration in his laws concerning the sinking fund.

“Money bearing compound interest grows at first slowly; but since the rate of increase is constantly accelerated, it becomes so fast after a while as to defy all imagination. A penny, loaned at the birth of our Savior at compound interest at 5%, would already have grown into a larger amount than would be contained in 150 million globes, all of solid gold. But loaned at simple interest, it would have grown only to 7 sh. 4½ d. in the same time. Hitherto our government has preferred to improve its finances in the latter instead of in the former way.”⁸¹

He flies still higher in his “Observations on Reversionary Payments, etc., London, 1782.” There we read: “1 sh. invested at the birth of our Savior” (presumably in the Temple of Jerusalem) “at 6% compound interest would have grown to a larger amount than the entire solar system could contain, if it were transformed into a globe of the diameter of the orbit of Saturn.” “A state need never to be in difficulties on this account; for with the smallest savings it can pay the largest debt in as short a time as its interests may demand.” (P. 136.) What a pretty theoretical introduction to the national debt of England!

Price was simply dazzled by the enormousness of the figures arising from geometrical progression. Since he regarded capital, without taking note of the conditions of reproduction and labor, as a self-regulating automaton, as a mere number increasing itself (just as Malthus did with men in their geometrical progression), he could imagine that he had found the law of its growth in the formula $s = c(1 + i)^n$, in which s stands for the sum of capital plus compound interest, c for the advanced capital, i for the rate of interest expressed in aliquot parts of 100, and n for the number of years in which this process takes place.

Pitt takes this mystification of Price quite seriously. In 1788 the House of Commons had resolved to raise one million pounds sterling for the public benefit. According to Price, in whom Pitt believed, there was, of course, nothing better than to tax the people, in order to “accumulate” this sum after raising it, and thus to spirit the national debt away by the mystery of compound interest. “The above resolution of the House of Commons was soon followed up by Pitt with a law, which ordered the accumulation of 250,000 pounds sterling, until, with the expired annuities, the fund should have grown to 4,000,000 pounds sterling annually.” (Act 26, George III, cha.) In his speech of 1792, in which Pitt proposed that the amount devoted to the sinking fund be increased, he mentioned among the causes of the

commercial supremacy of England machines, credit, etc., as “the most wide-spread and enduring cause of accumulation.” This principle, he said, was completely developed in the work of Smith, that genius, etc....And this accumulation, he continued, was accomplished by laying aside at least a portion of the annual profit for the purpose of increasing the principal, which was to be employed in the same manner next year, and which thus yielded a continual profit. By the help of Dr. Price, Pitt thus converted Smith’s theory of accumulation in an increase of popular wealth by means of the accumulation of debts, and in this way he gets into the pleasant progress of infinite loans, made for the purpose of paying loans.

Already Josiah Child, the father of modern banking, tells us that 100 pounds sterling at 10% will produce in 70 years by compound interest 102,400 pounds sterling. *Traité sur le commerce*, etc., par J. Child, traduit, etc., Amsterdam et Berlin, 1754, . Written in 1669.)

How thoughtlessly the conception of Dr. Price is applied by modern economists, is shown by the following passage of the “Economist”: “Capital, with compound interest on every portion of capital saved, is so all-engrossing that all the wealth in the world from which income is derived, has long ago become interest of capital....all rent is now the payment of interest on capital previously invested in the land.” (Economist, July 19th, 1859.) In its capacity of interest-bearing capital capital claims the ownership of all wealth which can ever be produced, and everything it has received so far is but an instalment for its all-engrossing appetite. By its innate laws, all surplus-labor belongs to it, which the human race can ever perform. Moloch.

In conclusion we present the following hodge-podge of the romantic Müller: “Dr. Price’s immense increase of compound interest, or of the self-accelerating forces of man, presuppose an undivided or unbroken order for several centuries, if they are to produce such enormous effects. As soon as capital is divided, cut up into several independently growing slips, the total process of accumulating forces begins anew. Nature has distributed the progression of power over a course of about 20 to 25 years, which fall on an average to the share of every laborer (!). After the lapse of this time the laborer leaves his track and must transfer the capital accumulated by the compound interest of labor to a new laborer, having to distribute it as a rule among several laborers or children. These must first learn to vitalise and employ their share of capital, before they can draw any actual compound

interest out of it. Furthermore, an enormous quantity of capital gained by bourgeois society is accumulated for many years, even in the most restless communities, and is not employed for any immediate expansion of labor, but rather entrusted to another individual, a laborer, a bank, a state, under the term of a loan, whenever a considerable amount has been gathered together. And in that case the one who receives it sets the capital into actual motion and draws compound interest out of it, so that he can easily agree to pay simple interest to the lender. Finally the laws of consumption, greed, waste, oppose those immense progressions, in which the forces of man and their products might increase, if the law of production or thrift were alone effective.” (A Müller, 1. c., II, -149.)

It is impossible to concoct a more hair-raising nonsense in a few lines. Leaving aside the droll confusion of laborer and capitalist, of value of labor-power and interest of capital, etc., the decrease of compound interest is supposed to be explained by lending capital at compound interest. This procedure of our Müller is characteristic of romanticism in all fields. It is made up of current prejudices, skimmed from the most superficial semblance of things. This false and trivial substance is then supposed to be “uplifted” and rendered poetical by a mystifying mode of expression.

The process of accumulation of capital may be conceived as an accumulation of compound interest in the sense that that portion of the profit (surplus-value), which is reconverted into capital, and serves to absorb more surplus-value, may be called interest. But

Aside from all accidental irregularities, a large part of the available capital is continually depreciated in the course of the process of reproduction, because the value of the commodities is not determined by the labor-time originally spent in their production, but by the labor-time spent in their reproduction, and this decreases continually in consequence of the development of the productivity of social labor. On a higher stage of development of the social productivity all available capital appears therefore as the result of a relatively short time of reproduction, instead of as the result of a long process of saving capital.⁸²

As we have proven in Part III of this volume, the rate of profit decreases in proportion as the accumulation of capital and the productivity of social labor corresponding to it increase, since these two express themselves precisely in a relative and progressive decrease of the variable portion of

capital as compared to the constant. In order to produce the same rate of profit, when the constant capital set in motion by one laborer increases tenfold, the surplus labor time would have to increase tenfold, and soon the total labor time, and finally the full 24 hours of a day, would not suffice, even if wholly appropriated by capital. The idea that the rate of profit does not decrease is, on the other hand, the basis of the progression of Price, as it is in general the basis of “all-engrossing capital with compound interest.”⁸³

By the identity of surplus-value with surplus-labor a qualitative limit is imposed upon the accumulation of capital. This is formed by the total working day, the prevailing development of the productive forces and of the population, which limit the number of the simultaneously exploitable working days. But if surplus value is conceived of in the meaningless form of interest, then the limit is merely quantitative and defies all fantasy.

Now, in the interest-bearing capital the idea of a capitalist fetish is perfected, the idea, which attributes to the accumulated product of labor, and at that in the fixed form of money, the power of creating surplus-value by its inherent secret qualities, in a purely automatic manner, and in geometrical progression, so that the accumulated product of labor, as the “Economist” thinks, has long discounted all the wealth of the world for all times as belonging to it and coming to it by right. The product of past labor, the past labor itself, is here pregnant in itself with a portion of present or future living surplus-labor. We know, on the contrary, that as a matter of fact the preservation, and to that extent the reproduction, of the value of the products of past labor is only the result of their contact with living labor; and secondly, that the control exerted by the products of past labor over living surplus-labor lasts only as long as the relations of capital, which rest on the definite social relation, in which past labor dominates independently over living labor.

CHAPTER XXV. CREDIT AND FICTITIOUS CAPITAL.

AN exhaustive analysis of the credit system and of the instruments created by it for its own use (credit money, etc.) is beyond the scope of our plan. We merely wish to dwell here upon a few particular points, which are necessary for a characterisation of the capitalist mode of production in general. To this end we shall deal only with commercial and bank credit. The connection between the development of this form of credit and that of public credit is not considered here.

I have shown previously (in volume I, chapter III, 3 b.), in what manner the function of money as a medium of payment, and consequently a relation of creditors and debtors, is formed among the producers of commodities and the traders, as the outcome of the simple circulation of commodities. With the development of commerce and of the capitalist mode of production, which has an eye only to the circulation, this natural basis of the credit system is extended, generalised, elaborated. Money serves here on the whole merely as a means of payment, that is to say, commodities are not sold for money, but for a written promise to pay for them at a certain date. We may comprise all these promises to pay for brevity's sake under the general category of bills of exchange. Such bills of exchange in their turn circulate as means of payment until the day on which they fall due; and they form commercial money in the strict meaning of the term. To the extent that they ultimately balance one another by the compensation of credits and debts, they serve absolutely as money, since no transformation into actual money takes place. Just as these mutual advances of the producers and merchants to one another form the real foundation of credit, so their instrument of circulation, the bill of exchange, forms the basis of credit money proper, of bank notes, etc. These do not rest upon the circulation of money, whether it be metallic money or government paper money, but upon the circulation of bills of exchange.

W. Leatham, a banker of Yorkshire, writes in his "Letters on the Currency," 2nd edition, London, 1840: "I find, that the total amount in bills of exchange for the entire year 1839 was 528,493,842 pounds sterling" (he assumed that the foreign bills of exchange composed about one-fifth of the

whole) “and the amount of bills of exchange simultaneously current in the same year to 132,123,460 pounds sterling” . “The bills of exchange make up a greater part of the amount in circulation than all the rest together” . “This enormous superstructure of bills of exchange rests (!) upon a basis formed by the amount of bank notes and gold; and if in the course of events this basis is too much contracted, its solidity, and even its existence, become endangered” . “Estimating the entire circulation” (he means of the bank notes) “and the amount of the obligations of all banks for which immediate payment may be demanded, I find a sum of 153 millions, whose conversion into gold might be demanded according to law, and to offset it only 14 millions in gold to satisfy this demand” . The bills of exchange cannot be placed under control, unless the superfluity of money and the low rate of interest, or discount, can be prevented, which create a part of them and encourage this dangerous expansion. It is impossible to decide, how much of them is due to actual business, for instance, to real purchases and sales, and what part of them is fictitious and consists only of prolonged bills, that is, when a bill of exchange is drawn for the purpose of taking up a current one before it becomes due, and thus of creating fictitious capital by the manufacture of mere means of circulation. In times of superfluous and cheap money I know this is done to an enormous degree” (, 44). J. W. Bosanquet, *Metallic, Paper, and Credit Currency*, London, 1842: The average amount of the payments settled on every business day in the Clearing House (where the London bankers mutually exchange the due bills and filed checks) exceeds 3 millions of pounds sterling, and the daily supply of money required for this purpose is little more than 200,000 pounds sterling . [In the year 1889, the total turn-over of the Clearing House amounted to 7,618 and $\frac{3}{4}$ millions of pounds sterling, which, in 300 business days, averages 25 and $\frac{1}{2}$ millions of pounds sterling daily. — F. E.] “Bills of exchange are undoubtedly currency, independent of money, inasmuch as they transfer property from hand to hand by endorsement” . “On an average it may be assumed that every circulating bill of exchange bears two endorsements, and that on an average every bill thus performs two payments, before it becomes due. Accordingly it seems that alone by endorsement the bills of exchange promoted a transfer of property to the amount of twice 528 millions, or 1,056 millions of pounds sterling, more than 3 millions daily, in the course of the year 1839. It is, therefore, certain the bills of exchange and deposits together, by transferring property from

hand to hand and without the assistance of money, perform the functions of money to a daily amount of at least 18 millions of pounds sterling” .

Tooke says the following about credit in general: “Credit, in its simplest expression, is the well or ill-founded confidence, which induces one man to entrust to another a certain amount of capital, in money or in commodities estimated at a certain value, which amount is always payable after the lapse of a definite time. Where the capital is loaned in money, that is, in bank notes, or in a cash credit, or in a check upon some correspondent, an addition of so and so many per cent. upon the returnable amount is made for the use of the capital. With commodities, whose money value has been agreed upon by the parties concerned, and whose transfer constitutes a sale, the stipulated sum, which is to be paid, includes a compensation for the use of the capital and for the risk assumed until the time of payment. Written agreements to pay on definite days are generally given for such credits. And these transferable obligations, or promises, form the means by which the lenders, when they find an opportunity to use their capital, either in the shape of money or commodities, are generally enabled to borrow or buy more cheaply, their own credit being strengthened by that of the second name upon the bill of exchange.” Inquiry into the Currency Principle, (.)

Ch. Coquelin, *Du Crédit et des Banques dans l' Industrie*. *Revue des deux Mondes*, 1842, tome 31: “In every country the majority of the credit transactions takes place in the circle of the industrial relations themselves...the producer of the raw material advances it to the capitalist, who works it up, and receives from him a promise to pay on a certain day. The manufacturer, having completed his share of the work, in his turn advances his product on similar conditions to another manufacturer, who has to manipulate it farther, and in this way credit extends more and more, from one to the other, down to the consumer. The wholesale dealer gives to the retail dealer commodities on credit, while he receives himself credit from a manufacturer or commission agent. All borrow with one hand and lend with the other, sometimes money, but more frequently products. In this manner an incessant exchange of credits, combining and crossing in all directions, takes place in the industrial relations. The development of credit consists precisely in the multiplication and growth of these mutual credits, and here is the real seat of its power.”

The other side of the credit system is connected with the development of the money trade, which, of course, keeps step under capitalist production

with the development of the trade in commodities. We have seen in the preceding part (chapter XIX), how the care of reserve funds of business men, the technical operations of receiving and issuing money, of international payments, and thus of the bullion trade, are concentrated in the hands of the money traders. Borrowing and lending money becomes their particular business. They step as middlemen between the actual lender and the borrower of capital. Generally speaking, the banking business on this side consists of concentrating the loanable money-capital in the banker's hands in large masses, so that in place of the individual money lender the bankers face the industrial capitalists and commercial capitalists in the capacity of representatives of all money lenders. They become the general managers of the money-capital. On the other hand, they concentrate the borrowers against all lenders, and borrow for the entire world of commerce. A bank represents on one hand the centralisation of money-capital, of the lenders, and on the other the centralisation of the borrowers. Its profit is generally made by borrowing at a lower rate of interest than it loans.

The loanable capital, of which the banks dispose, flows to them in various ways. In the first place, since they are the cashiers of the industrial capitalists, there is concentrated into their hands the money-capital, which every producer and merchant must have as a reserve fund, or which he receives in payment. These funds are thus converted into loanable capital. In this way the reserve fund of the commercial world, being concentrated into a common treasury, is reduced to its necessary minimum, and a portion of the money-capital, which would otherwise slumber as a reserve fund, is loaned and serves as interest-bearing capital. In the second place, the loanable capital of the banks is formed by the deposits of the money-capitalists, who entrust them with the business of loaning it. Furthermore, with the development of the bank system, and particularly as soon as they pay interest on deposits, the money savings and the temporarily unemployed money of all classes are deposited with them. Small amounts, each by itself incapable of acting in the capacity of money-capital, are combined into large masses and thus form a money power. This aggregation of small amounts must be distinguished as a specific effect of the bank system from its intermediate position between the money-capitalists proper and the borrowers. Finally, the revenues, which are but gradually consumed, are also deposited with the banks.

The loan is made (we refer here only to the commercial credit in the strict meaning of the term) by discounting bills of exchange, that is, by converting them into money before they come due, and by advances in various forms: direct advances on personal credit, Lombard loans on interest-bearing papers, government papers, stocks of all kinds, furthermore advances on bills of lading, dock warrants, and other certified titles of ownership in commodities, and by overdrawing on their deposits, etc.

The credit given by a banker may assume various forms, for instance, that of exchanges on other banks, checks on them, opening of credit in the same way, finally, in the case of banks entitled to issue notes, the bank notes of the bank itself. A bank note is nothing but a draft upon the banker, payable at any time to the bearer, and substituted by the banker for private drafts. This last form of credit appears particularly important and striking to the layman, first, because this form of credit money steps from the mere commercial circulation into the general circulation and serves as money there, and in the second place, because in most countries the principal banks issuing notes represent a queer mixture of national and private banks and thus have actually the national credit to back them up and give to their notes the character of a more or less legal tender, for in this case it is apparent, that the thing which the banker handles is credit itself, since a bank note stands only for a circulating token of credit. But the banker also deals in all other forms of credit, even when he advances cash money deposited with him. In fact, a bank note simply represents the coin of wholesale trade, and it is always the deposit, which carries the most weight with banks. The best proof of this is furnished by the Scotch banks.

The special credit institutions, and the particular forms of banks, do not require any further consideration for our purposes.

The banks have a twofold business.... 1) To collect capital from those, who have no immediate use for it, and to distribute it and transfer it to others, who can use it. 2) To receive deposits from the incomes of their customers and to pay them whatever amount they may require of this deposit for the expenses of consumption. The former is circulation of capital, the latter circulation of currency. — The one is a concentration of capital on one side, and its distribution on the other; the other is a management of the circulation for the local needs of the vicinity. — Tooke, *Inquiry into the Currency Principle*, , 37. — We shall revert to this passage later, in chapter XXVIII.

Reports of Committees. Vol. VIII., Commercial Distress. Vol. II., Part I., 1847-48, Minutes of Evidence. (Subsequently quoted as Commercial Distress, 1847-48.) In the forties, when discounting bills of exchange in London, bills of exchange of one bank were often drawn on another instead of bank notes. (Testimony of J. Pease, provincial banker, No. 4636 and 4656.) According to the same report, the bankers were in the habit of giving such bills of exchange in payment to their customers, as soon as money grew tight. If the party receiving them demanded bank notes, he had to discount this bill of exchange once more. This amounted to a privilege of making money for the banks. Messieurs Jones, Lloyd and Co., made payments in this way “since time immemorial,” as soon as money was scarce and the rate of interest above 5%. The customer was glad to get such banker’s bills, because bills of Jones, Lloyd and Co. could be easier discounted than his own; these bills often passed through twenty to thirty hands. (Ibidem, No. 901 to 904, 905.)

All these forms serve to make a claim to payments transferable. — There is scarcely one form, which credit may assume, in which it has not at times performed the functions of money; whether this form is that of a bank note, or of a bill, or of a check, the process is essentially the same and the result is essentially the same. Fullarton, On the Regulation of Currencies, 2d edition, London, 1845, . — Bank notes are the small currency of credit. . —

The following is from J. W. Gilbart The History and Principles of Banking, London, 1834: The capital of a bank consists of two parts, the invested capital and the banking capital, which is borrowed (et seq.). The banking capital, or borrowed capital, is maintained in three ways: 1) through the acceptance of deposits; 2) through the issuing of the bank’s own notes; 3) through the drawing of bills. If some one is willing to loan me 100 p.st. for nothing, and I loan these 100 p.st. to some one else at 4%, I shall make 4 p.st. by this transaction in the course of one year. Likewise if some one is willing to accept my promise to pay and to return it to me at the end of the year and to pay me 4% for it, just as though I had given him 100 p.st. by this transaction, I make 4 p.st. by it; and again, if a man in a country town brings me 100 p.st. on the condition that I shall pay this amount to some third person in London after the lapse of 21 days, all the interest I may draw in the meantime on this money will be my profit. This is an objective summary of the operations of a bank and of the way in which a banking capital is created by deposits, bank notes and bills of exchange . The profits

of a banker are generally proportionate to the amount of his borrowed or banking capital. In order to determine the actual profit of a bank, the interest on the first investment of capital must be deducted from the gross profits. The remainder is the banking profit . The advances of a banker to his customers are made with the money of other people . Precisely those bankers, who do not issue any bank notes, create a banking capital by discounting bills of exchange. They increase their deposits by their discounting operations. The London banks discount only for those firms, that keep a deposit in account with them . A firm discounting bills of exchange in its bank and having paid interest upon the whole amount of these bills must leave at least a portion of this amount in the hands of the bank without receiving any interest on it. In this way the banker receives a higher rate of interest than the current one on the advanced money and creates for himself a banking capital by means of the surplus remaining in his hands. (.) — Economising of reserve funds, deposits, checks: The deposit banks economise by a transfer of credit accounts the use of the circulating medium and transact business of a large volume with a small amount of actual money. The money thus released is employed by the banker in making advances to his customers by means of discounts, etc. Hence the transfer of credit enhances the effectiveness of the deposit system . It is immaterial, whether the two customers, that deal with one another, keep their accounts with the same or with different bankers. For the bankers exchange their checks among themselves in the Clearing House. By means of transfers the deposit system might be extended to such a degree that it would do away entirely with the use of metal money. If every one were to keep a deposit account in the bank and to make payments by means of checks then such checks would be the only circulating medium. In this case the assumption would have to be that the bankers hold the money in their hands, otherwise the checks would have no value . The centralisation of the local transactions in the hands of the banks is promoted, 1) by branch banks. The provincial banks have branch establishments in the smaller towns of their district the London banks in the different quarters of the city. 2) By agencies. Every provincial bank has its agent in London, in order to pay its notes or bills there and to receive money, which is paid down by inhabitants of London for the account of people living in the provinces. (.) Every banker gathers in the notes of the others and holds them. In every large city they meet once or twice a week and exchange their notes. The

balance is paid by a check on London. (.) The purpose of banks is to facilitate business. Whatever facilitates business, facilitates also speculation. Business and speculation are so closely linked in some cases, that it is difficult to tell where business stops and speculation begins. Wherever there are banks, capital can be obtained more easily and cheaply. The cheapness of capital promotes speculation, just as the cheapness of beer and meat promotes gluttony and drunkenness (, 138). Since the banks issuing their own notes always pay in these notes, it may seem as though their discount business were transacted exclusively with the capital made in this way, but this is not so. A banker may very well pay all the bills discounted by him with his own notes, and yet nine-tenths of the bills in his possession may represent actual capital. For while he may have given only his own paper money for these bills, it need not stay in the circulation until these bills become due. The bills may be running for three months, while the notes may return in three days. (.) The overdrawing of accounts by customers is a regular business practice. This is indeed the purpose, for which cash credit is granted. Cash credits are not granted on personal security, but on deposit of collateral papers (, 175). A capital advanced on bonded wares has the same effect as though it had been advanced in discounting bills. If a man borrows 100 p.st on his goods as a security, it is the same as though he had sold them for a bill of exchange of 100 p.st. and discounted this bill with his banker. But this advance enables him to hold his goods over for a better condition of the market and to avoid sacrifices, which he would have had to make, in order to obtain money for urgent purposes (, 181).

The Currency Question Reviewed, etc., , 63: It is here indisputably true that the 1,000 p.st. which I deposit to-day with A are issued to-morrow and deposited with B. The day after to-morrow it may be issued once more by B and form a deposit with C, and so forth infinitely. The same 1,000 p.st. of money may, therefore, multiply themselves into an absolutely indeterminable sum of deposits by a series of transfers. Hence it is possible that nine-tenths of all deposits in England may have no other existence but that in the entries of the banker's books, of whom every one stands good for his part of them. In Scotland, for instance, the money in circulation (and mostly paper money at that) never exceeds 3 million p.st., while the deposits amount to 27 millions. So long as no general and sudden demand is made for the return of the deposits (a run on the bank), the same 1,000 p.st.,

traveling backward, may balance an equally indeterminable sum with the same facility. Since the same 1,000 p.st., with which I balance to-day my debt with some business man, may balance to-morrow his debt with some other business man, and the day after to-morrow balance this man's account, and so forth infinitely, it follows that the same 1,000 p.st. may pass from hand to hand and from bank to bank and balance any imaginable sum of deposits.

[We have seen, that Gilbart knew even in 1834 that "whatever facilitates business facilitates speculation, both being so intimately linked in many cases, that it is difficult to tell, where business stops and speculation begins." If the securing of advances on unsold commodities is facilitated more and more, then more and more of such advances are taken, and in the same proportion increases the temptation to manufacture commodities, or throw already manufactured ones upon distant markets, for no other immediate purpose than that of obtaining advances of money on them. To what extent the entire business world of a country may be seized by such a swindle, and what it finally comes to, may be studied in the history of English business during the years 1845 to 1847, which furnishes a flagrant example. There we can see what credit can accomplish. Before we mention some of the most conspicuous cases, we must make a few preliminary remarks.

About the close of 1842 the pressure, which had crushed English industry almost without interruption since 1837, began to weaken. During the following two years the demand of the foreign countries for products of English industry increased still more. The year 1845 to 1846 marked the period of greatest prosperity. In 1843 the opium war had opened the doors of China to English commerce. The new market offered a convenient excuse for the further expansion of already extended industries, particularly of the cotton industry. "How can we ever produce too much? We have to clothe 300 millions of people." Thus spoke a Manchester manufacturer to the writer in those days. But all the newly erected factory buildings, steam engines, spinning and weaving machines did not suffice to absorb the surplus-value, which poured into them from Lancashire. With the same passion, which was exhibited in the expansion of production, the building of railroads was undertaken. Here the longing of manufacturers and merchants for speculation found its first satisfaction, as early as the summer of 1844. Stock was underwritten to the full extent possible, that is, so far as

the money went to cover the first payments. The idea was that a way would be found in due time to get the missing amount. But when further payments were due (Question 1059, C. D. 1848-57, indicates that the capital invested in railroads in 1846-47 amounted to 75 million p.st.), it was necessary to resort to credit, and as a rule the actual business of the firm itself had to add its drop of blood.

In most cases the actual business was already overburdened. The enticing and high prices had misled people into far greater operations than the available cash justified. It was so easy, and cheap besides, to get credit. The bank discount was low. In 1844 it was $1\frac{3}{4}$ to $2\frac{3}{4}\%$, in 1845 until October it was less than 3%, then it rose for a little while to 5% (until February 1846), then it fell once more to $3\frac{1}{4}\%$ in December 1846. The bank had in its cellars a supply of gold of unusual dimensions. All inland quotations stood higher than ever before. Why should a man let this fine opportunity pass by? Why shouldn't he go in for all he was worth? Why not send to the foreign markets, that longed for English goods, all the commodities that could be manufactured? And why should not the manufacturer himself pocket the double gain arising from the sale of yarn and fabrics to the Far East, and from the sale, in England, of the back freight received in their stead?

Thus arose the system of mass consignments, by virtue of advances, to India and China, and this soon developed into a system of consignments purely for the sake of getting advances, as described more at length in the following notes. This had to lead inevitably to an overcrowding of the markets and to a crash.

This crash came as the aftermath of a crop failure in 1846. England, and still more, Ireland, required enormous imports of means of subsistence, particularly of corn and potatoes. But the countries that supplied these things could be paid only to a very small degree in products of English industry. They had to be paid in precious metals. This took at least nine millions of gold to foreign countries. Of this amount of gold fully seven and a half millions came out of the cash treasury of the Bank of England, whose freedom of action on the money market was seriously impaired thereby. The other banks, whose reserves are deposited with the Bank of England, which reserves are practically identical with those of the Bank of England, were thus compelled to cut down their own money accommodations. The rapidly and easily flowing stream of payments became clogged, first here and there,

then universally. The banking discount, which had still been 3 to 3½% in January of 1847, rose to 7% in April, when the first panic broke out. Then a temporary lull came in summer, lowering this discount to 6½ and 6 %. But when the new crop failed likewise, the panic broke out afresh and more violently. The official minimum discount of the Bank rose in October to 7%, in November to 10%, in other words, the overwhelming mass of checks could be discounted only at outrageous rates of interest, or not at all. The general stopping of payments brought about the bankruptcy of several of the first firms and of very many medium-sized and small firms. The Bank itself was in danger of ruin from the shrewd Bank Acts imposing the limitations of 1844. In this emergency the government yielded to the universal demand and suspended these Bank Acts on October 25, thereby taking off the absurd legal fetters thrown around the Bank. Now the Bank was enabled to throw its supply of bank notes into circulation without any interference. The credit of these bank notes being practically guaranteed by the credit of the nation, and thus unimpaired, the shortness of money was immediately relieved in the most effective manner. Of course, quite a number of hopelessly caught large and small firms failed nevertheless even then, but the climax of the crisis had passed, the banking discount fell once more to 5% in September, and in the course of 1848 that renewed business activity was resumed, which took the edge off the revolutionary movements on the continent in 1849, and which inaugurated in the fifties a formerly unknown industrial prosperity and ended — in the crash of 1857. — F. E.]

A document issued by the House of Lords in 1848 gives information concerning the depreciation of government papers and bonds during the crisis of 1847. According to it the depreciation of October 23, 1847, compared to the stand of values in February of the same year, amounted to 93,824,217 pounds sterling in English government bonds, 1,358,288 pounds sterling in dock and canal stock, and to 19,579,820 pounds sterling in railroad stocks, a total of 114,762,325 pounds sterling.

With reference to the swindle in East Indian business, in which it was no longer a question of making drafts, because commodities had been bought, but rather of buying commodities in order to be able to make out discountable drafts which should be convertible into money, the “Manchester Guardian” of November 24, 1848, remarks that Mr. A in London instructs a Mr. B to buy from the manufacturer C in Manchester commodities for shipment to a Mr. D. in East India. B pays C in six-

months-drafts to be made by C on B. B secures himself by six-months-drafts on A. As soon as the goods are shipped, and the bill of lading mailed, A makes out six-months-drafts on D. The buyer and shipper thus get possession of funds many months before the goods are actually paid for. And it was a common custom to renew the drafts when due under the pretense of allowing time for turn-over in such a protracted business. Unfortunately the losses in this business did not lead to its restriction, but to its extension. In proportion as the interested parties grew poor their need of making purchases increased, in order to find in new advances a compensation for capital lost in previous speculations. Purchases were then no longer regulated by supply and demand, but became the most important feature in the financial operations of a shaky firm. But this is only one side of the picture. What happened in the export of manufacturing goods here, occurred in the purchase and shipment of goods on the other side. Firms in India, which had credit enough to get their checks discounted, bought sugar, indigo, silk or cotton, not because the purchase prices as compared with the latest London quotations promised a profit, but because previous drafts on a London firm would soon be due and would have to be covered. What was simpler than to buy a cargo of sugar, to pay for it in ten-months-drafts on the London firm, and to send the bills of lading by overland mail to London? Less than two months later the bills of lading of these barely shipped goods, and thus the goods themselves, were pawned in Lombard Street, and the London house came into the possession of money eight months before the bills of exchange made out for these goods were due. And all this passed off smoothly, without interruption or difficulties, so long as the discounting firms found enough money to advance on bills of lading and dock warrants, and to discount the drafts of Indian firms on select firms of Mincing Lane to unlimited amounts.

[This fraudulent procedure remained in vogue so long as the goods from and to India had to sail around the Cape. But since they pass through the Suez Canal this method of creating fictitious capital has lost its foundation, thanks to steam navigation and the shortening of the trip. And when the telegraph reported the stand of the Indian market to the English and that of the English market to the Indian business man on the same day, this method was completely killed. F. E.]

The following is from the previously quoted report on Commercial Distress, 1847-48: In the last week of April, 1847, the Bank of England informed the Royal Bank of Liverpool, that it would henceforth reduce its discount business with the latter bank by one-half. This communication had a very disastrous effect, because the payments in Liverpool had lately been made far more in bills of exchange than in cash, and because the merchants, who ordinarily carried much cash money to the bank for the purpose of squaring their notes, had been able to bring only checks of late, which they had received themselves for their cotton and other products. This had assumed large proportions and caused the business difficulty. The endorsed checks, which the bank had to turn into cash for the merchants, had mostly been made out by outsiders, and had so far been balanced generally by the payments received for the products. The checks which the merchants now brought in place of the former cash were bills of exchange for different lengths of time and of different kinds, a considerable number being bank checks for three months from date, the majority being checks for cotton. These bills of exchange, when bank checks, had been endorsed by London bankers, the others were endorsed by merchants in Brazilian, American, Canadian, West Indian, etc., business... The merchants did not draw on one another, but the customers in the home country, who had bought products in Liverpool, covered them by drafts on London banks, or drafts on other firms in London, or on drafts of some one else. The communication of the Bank of England caused a shortening of the running time of checks drawn against sales of foreign products, which used to run frequently longer than three months. (, 27.)

The period of prosperity in England, from 1844 to 1847 was, as described above, connected with the first great railroad swindle. The above-named report makes the following statements concerning the influence of this swindle on business in general: In April, 1847, nearly all commercial firms had begun to starve their business more or less, by investing a part of their commercial capital in railroads (.) — Loans were also made by private parties, bankers and insurance companies at a high rate of interest, for instance, at 8% . These large advances of these business firms to railroads caused them to take up in their turn too much capital from banks on discount checks, by which to carry on their own business (. — (Question): Would you say that the payments on railroad stocks contributed much to the pressure which burdened the money market in April and

October 1847? (Answer): I believe that they hardly contributed anything to the pressure in April. In my opinion they had rather strengthened than weakened the bankers going on into April, and perhaps even into the summer. For the actual employment of the money followed by no means as rapidly as the deposits; as a result most of the banks had a rather large amount of railroad stocks in their hands in the beginning of the year. [This is corroborated by numerous statements of bankers in C. D. 1848-57.] This gradually melted away in summer and was considerably smaller on December 31. One cause of the pressure in October was the gradual decrease of the railroad funds in the hands of bankers; between April 22, and December 31, the balances of railroads in our hands were reduced by one-third. This effect was produced by railroad deposits in all of Great Britain; they have gradually stripped the banks of deposits (, 44). — Samuel Gurney (Chief of the ill-famed firm of Overend Gurney & Co.) says likewise: In 1846 there was a much greater demand for capital for railways, but it did not raise the rate of interest. There was a condensation of small sums into larger masses, and these larger masses were consumed in our market; so that on the whole the effect was to throw more money on the money market of the city, not so much to take it out.

Hodgson, Director of the Liverpool Joint Stock Bank, shows to what extent bills of exchange may form a reserve for bankers: It was our custom to hold at least nine-tenths of all our deposits, and all money received from our customers, in our bill books in the shape of bills of exchange, which fell due from day to day...so much so, that the amount of bills due daily during the time of the crisis almost equaled the amount of demands for payment made on us every day .

Speculative Bills. — No. 5092. “By whom were the bills of exchange (against sold cotton) mainly endorsed?” — (R. Gardner, the cotton manufacturer mentioned several times in this work): “By produce jobbers; one trader buys cotton, transfers it to some jobber, draws checks on this jobber, and gets these bills discounted.” — No. 5094. “And these bills of exchange go to the Liverpool banks and are discounted by them?” — “Yes, and also by others....Had not this accommodation existed, which was mainly allowed by the Liverpool banks, cotton would have been, in my opinion, from 1½ d to 2 d per pound cheaper last year.” — No. 600. “You said that an enormous number of bills of exchange was in circulation, drawn by speculators upon cotton jobbers in Liverpool; does the same apply

to your advances on bills of exchange for other colonial products than cotton?” — (A. Hodgson, banker in Liverpool): “It refers to all kinds of colonial products, but most particularly to cotton.” — No. 601. “Do you, as a banker, try to keep away from bills of exchange of this sort?” — “Not at all; we regard them as legitimate bills when kept within moderate bounds....This sort of bills is often prolonged.”

Swindle in the East Indian and Chinese Market, 1847. — Charles Turner (Chief of one of the first East Indian firms in Liverpool): “We all know the occurrences, which have taken place in the matter of business to Mauritius and similar businesses. The jobbers were accustomed to make advances on goods, not only after their arrival, for the covering of the bills of exchange drawn for these goods, which is quite in order, and advances on bills of lading...they have also made advances on the product before it had been shipped, and in some cases before it had been manufactured. For instance, I had, in one case in Calcutta, bought bills of exchange amounting to 6-7,000 pounds sterling; the proceeds of these goods went to Mauritius in order to assist in planting sugar there; the bills came to England, and more than half of them were protested; then, when the shipments of sugar finally arrived, by which these bills were to have been paid, it was found that this sugar had already been pawned to third parties, before it had been shipped, or even before it had been boiled. Now the goods for the East Indian market must be paid to the manufacturer in cash; but this does not mean much, for if the buyer has some credit in London, he draws on London and discounts the drafts in London, where the discount is now low; he pays the manufacturer with the money so obtained...it takes at least twelve months before a shipper of goods to India receives his return shipment...a man with ten or fifteen thousand pounds sterling going into Indian business would secure credit from some London house to a considerable amount; he would give to this house 1% and draw on it with the understanding, that the proceeds of the goods sent to India are to be sent to this London house; but the tacit understanding on both sides is that the London house shall not have to make any advances of cash; in other words, the drafts are prolonged until the return shipments arrive. The bills of exchange are discounted in Liverpool, Manchester, London, some of them are held by Scotch banks” . — No. 730. “There is a firm, which recently failed in London; the examination of its books revealed the following condition of affairs: Here is one firm in Manchester, and another in Calcutta; they opened a credit with

the London firm for 200,000 pounds sterling; that is, the business friends of this Manchester firm, who sent consignments of goods from Glasgow and Manchester to the firm in Calcutta, drew on the London house up to the sum of 200,000 pounds sterling; at the same time the understanding was, that the Calcutta firm would also draw on the London firm up to the sum of 200,000 pounds sterling; these bills of exchange were sold in Calcutta, other bills of exchange were bought with the proceeds, and these were sent to London in order to enable the firm there to pay the first drafts made by the Glasgow or Manchester firm. In this way this firm sent bills of exchange amounting to 600,000 pounds sterling into the world.” — No. 971. “At present, when a firm in Calcutta buys a ship’s cargo (for England) and pays for it with its own drafts on its London correspondent, and when the bills of lading are sent here, these bills of lading are used immediately for the purpose of securing advances in Lombard Street; hence they have eight months time in which to make use of the money before their correspondents have to pay the drafts.” —

In the year 1848 a secret committee of the Upper House was in session on an investigation of the causes of the crisis of 1847. The testimony of the witnesses before this committee was not published, however, until 1857 (Minutes of Evidence, taken before the Secret Committee of the H. of L. appointed to inquire into the Causes of Distress, etc., 1857; quoted as C. D. 1848-57). Here Mr. Lister, the Director of the Union Bank of Liverpool, testified among other things to the following: 2444. “There was, in the spring of 1847, an unwarranted extension of credit...because business men transferred their capital from their business to railroads and nevertheless wanted to continue their business on the old scale. Every one thought probably at first that he could sell the railroad stocks at a profit and thus replace the money in the business. He found, perhaps, that this was impossible, and then secured credit in his business where he paid cash formerly. This gave rise to an extension of credit.”

2500. “These bills of exchange, on which the banks that had accepted them incurred losses, were they bills mainly for corn or for cotton?...They were bills for products of all kinds, corn, cotton and sugar, and products of all sorts. There was at that time nothing, with the exception of oil, perhaps, that did not fall in price.” — 2506. “A jobber, who accepts a bill of exchange, does not do so without being sufficiently secured, also against a fall in the price of the commodity which serves as a security.”

2512. “Two kinds of bills of exchange are drawn for products. To the first kind belongs the original draft, which is made out on the other side on the importer....The drafts which are made out in this way for products are frequently due before the goods arrive. For this reason the merchant who has not enough money when the products arrive, must pawn them to some broker until he can sell them. Then a draft of the other kind is immediately drawn on the broker by the Liverpool merchant, on the strength of those products...it then becomes the business of the banker to ascertain, whether he has those goods and to what extent he has made advances on them. He must convince himself, that the broker has security, in order to make good eventual losses.”

2516. “We receive also bills of exchange from foreign countries....Some one buys on the other side a bill of exchange on England, and sends it to some firm in England; we cannot tell by looking at this bill, whether it has been drawn reasonably or unreasonably, whether it represents products or wind.”

2533. “You said that foreign products of nearly all kinds are sold at a heavy loss. Do you believe, that this was due to unwarranted speculations in these products?” — “It arose from a very large import, while no adequate consumption existed to take care of it. From all indications the consumption fell off considerably.” — 2537. “In October...products were almost unsaleable.”

How it is that a general scramble for safety is made at the critical stage of a crisis is explained in the same report by an expert of the first order, the worthy and crafty Quaker, Samuel Gurney of Overend Gurney & Co.: 1262. “When a panic reigns, a business man does not ask himself, how profitably he can invest his bank notes, or whether he will lose 1 or 2% in the sale of his treasury notes or 3% bonds. Once that he is under the suggestions of fright, he cares nothing about gain or loss; he gets himself into a safe place, the rest of the world may do what it pleases.”

Concerning the mutual unmasking of two markets Mr. Alexander, a merchant in the East Indian trade, testifies before the Committee of the Lower House on the Bank Acts of 1857 (quoted as B. C. 1857): 4330. “At present, if I invest 6 shillings in Manchester, I get 5 shillings back in India; if I invest 6 shillings in India, I get 5 shillings back in London.” In this way the Indian market is exposed by England, and the English by India. And this

took place in the summer of 1857, barely ten years after the bitter experience of 1847!

CHAPTER XXVI. ACCUMULATION OF MONEY-CAPITAL. ITS INFLUENCE ON THE RATE OF INTEREST.

“IN England, a steady accumulation of additional wealth takes place, which has a tendency to assume ultimately the form of money. But next to the desire to acquire money, the most insistent desire is that of disposing of it by some kind of investment bringing interest or profit; for money as money does not bring wealth. Unless, therefore, a gradual and adequate extension of the field of investment takes place simultaneously with this steady accession of additional capital, we must be exposed to periodical accumulations of money seeking investment, which will be of greater or smaller importance according to circumstances. For a long series of years the national debt was the great means of absorbing the superfluous wealth of England. Since it reached its maximum in 1816 and no longer acts as an absorbent, every year a sum of at least 27 millions has been seeking other fields of investment. Moreover, various return payments of capital were made....Enterprises which require a large capital for their execution and make an opening from time to time for the excess of unemployed capital...are absolutely necessary, at least in our country, in order to take care of the periodical accumulations of the superfluous wealth of society, which cannot find room in the ordinary fields of investment.” (The Currency Question Reviewed, London, 1845, .) Of the year 1845 the same work says: “Within a very short period the prices have leaped upward from the lowest point of depression....The 3% national debt stands almost at par....The gold in the vaults of the Bank of England exceeds all former amounts stored away there. Stocks of all kinds are quoted at prices, which are unheard of in almost every case, and the rate of interest has fallen so much, that it is nearly nominal....All these are proofs that another heavy accumulation of unemployed wealth exists in England, that another period of speculative overheating is imminent.” (Ibidem, p 35.)

“Although the import of gold is not a reliable indication of profit in foreign commerce, nevertheless a part of this import of gold, in the absence of any other explanation, represents on its face such a profit.” (J. G. Hubbard, The Currency and the Country, London, 1843, .) Take it that in a

period of good steady business, profitable prices, and well supplied circulation of money, a crop failure gives rise to an export of 5 millions of gold and to an import of corn to the same amount. The circulation” (meaning, as we shall see immediately, the unemployed money-capital, not the medium of circulation. F. E.) “is reduced by the same amount. The private individuals may still possess means of circulation to the same amount, but the deposits of the merchants in the banks, the outstanding balances of the banks with their money brokers, and the reserves in their treasuries will all be reduced, and the immediate result of this reduction to the amount of the unemployed capital will be a rise in the rate of interest, say from 4% to 5%. Since business is sound, confidence is not shaken, but credit will be valued more highly.” (Ibidem, .) “If the prices of commodities fall universally, the superfluous money flows back to the banks in the form of increased deposits, the plethora of unemployed capital reduces the rate of interest to a minimum, and this condition of affairs lasts until either higher prices or a brisker business call the slumbering money into service, or until it has been absorbed by investment in foreign securities or foreign commodities.” (P. 68.)

The following extracts are once more taken from the parliamentary report on Commercial Distress, 1847-57. — In consequence of the crop failure and famine of 1846-47 a heavy import of means of subsistence was necessary. “Hence a great excess of imports over exports....Hence a considerable drain of money from banks, and an increased demand upon the discount brokers from people who had bills of exchange to discount; the brokers began to inspect the bills of exchange more closely. The accommodation hitherto granted was seriously restricted, and weak houses failed. Those who relied wholly upon credit went to the wall. This increased the already marked unrest; bankers and others found, that they could not be as certain as formerly of transforming their bills of exchange and other securities into bank notes, in order to fulfill their obligations; they restricted the accommodation still more and frequently refused it altogether; they locked their bank notes up in many instances, in order to meet their own future obligations; they preferred not to let go of them at all. The unrest and confusion increased daily, and without the letter of Lord John Russel the general bankruptcy was imminent.” (P. 74-75.) The letter of Russel suspended the Bank Acts. — The previously mentioned Charles Turner testifies: “Some firms had large means, but they were not available. Their

entire capital was tied up in real estate in Mauritius, or in indigo or sugar factories. Once that they had contracted obligations for 5 or 600,000 pounds sterling, they had no means free for the payment of bills of exchange, and finally it was seen, that they could pay their bills of exchange only by means of credit, and so far as that went.” (P. 81.) — The aforesaid S. Gurney said: “At present (1848) there prevails a contraction of business and a great plethora of money. — No. 1763. I do not believe that it was a lack of capital, which drove the rate of interest so high; it was the alarm, the difficulty of obtaining bank notes.”

In 1847 England paid at least nine million pounds sterling in gold to foreign countries for imported means of subsistence. Of this amount seven and a half millions came from the bank of England and one and a half million from other sources. (P. 245.) — Morris, the Governor of the Bank of England: “On October 23, 1847, the public funds and the canal and railroad stocks were already depreciated by 114,752,225 million pounds sterling.” (P. 312.) The same Morris, when questioned by Lord G. Bentinck: “Is it not known to you that all capital invested in papers and products of all kinds was depreciated in the same way, that raw materials, cotton, silk, wool were sent to the continent at the same cut prices, and that sugar, coffee and tea were auctioned off in forced sales?”— “It was inevitable that the nation should make considerable sacrifices, in order to counteract the drain of gold caused by the enormous imports of means of subsistence.”— “Don’t you believe that it would have been better to touch the eight million pounds sterling stored in the vaults of the bank, instead of trying to recover the gold with such sacrifices?”— “I do not believe that.” — Now to the commentaries on this heroism. Disraeli questions Mr. W. Cotton, the Director and former Governor of the Bank of England. “What was the dividend received by the stockholders of the bank in 1844?”— “It was 7% for that year.”— “And the dividend for 1847?”— “Nine per cent.”— “Does the bank pay the income tax for its stockholders in the current year?”— “Yes, Sir.”— “Did it do so in 1844?”— “No, Sir.”⁸⁴— “Then this Bank Act (of 1844) worked very much to the advantage of the stockholders....The result is, then, that since the introduction of the new Act the dividend of the stockholders has risen from 7% to 9%, and that the income tax is now also paid by the bank, while formerly it had to be paid by the stockholders?”— “That is quite right.” — (No. 4356-4361.)

Concerning the formation of hoards in banks during the crisis of 1847, Mr. Pease, a provincial banker, has the following to say: 4605. “As the bank was compelled to raise its rate of interest more and more, the apprehension grew universally; the rural banks increased the quantities of money in their possession and likewise the amounts of their notes; and many of us, who would ordinarily carry only a few hundred pounds in gold or bank notes, stored up at once thousands in cash boxes and desks, since there was great uncertainty concerning the discount and the possibility of circulating bills of exchange on the market; and consequently a universal accumulation of hoards ensued.” — A member of the Committee remarks: 4691. “Accordingly, whatever may have been the cause during the last 12 years, the result was certainly more in favor of the Jew and the money broker than in favor of the productive class in general.”

To what extent a money broker exploits times of crisis, is revealed by Tooke: “In the metal ware business of Warwickshire and Staffordshire very many orders were rejected in 1847, because the rate of interest, which the manufacturer had to pay for discounting his bills of exchange, would have more than swallowed his entire profit.” (No. 5451.)

Let us now take another report of Parliament, the Report of the Select Committee on Bank Acts, communicated from the Commons to the Lords, 1857 (quoted further along as B. C. 1857). In it Mr. Norman, Director of the Bank of England and a leading light among the champions of the Currency Principle, is questioned as follows:

3635. “You said you were of the opinion, that the rate of interest depends, not on the mass of bank notes, but on the demand and supply of capital. Would you state, what you comprise under the head of capital, outside of bank notes and hard cash?” — “I believe the general definition of capital is: Commodities or services used in production. — 3636. “Do you include all commodities in the term capital, when you speak of the rate of interest?” — “All commodities used in production.” — 3637. “You include all that in the term capital, when you speak of the rate of interest?” — “Yes, Sir. Let us assume that a cotton manufacturer needs cotton for his factory, then he will probably secure it by obtaining an advance from his banker, and with the money so obtained he will go to Liverpool and buy. What he really needs is cotton; he does not need the bank notes or the money except as means of getting the cotton. Or he may need the means to pay his laborers; then he again borrows notes and pays the wages of his laborers

with them; and the laborers on their part need food and shelter, and the money is a means of paying for them.” — 3638. “But interest is paid for this money?”— “Yes, Sir, in the first instance; but take another case. Take it that he buys the cotton on credit, without getting any advance from the bank; then the difference between the price for cash payment and the price on credit at the time when payment is due is the measure of the interest. There would be interest even if no money existed.”

This self-complacent rubbish is quite worthy of this pillar of the Currency Principle. First the brilliant discovery, that bank notes or gold are means of buying something, and that they are not borrowed for their own sake. And this is supposed to explain, that the rate of interest is regulated, by what? By the demand and supply of commodities, that were so far known to regulate only the market prices of commodities. But very different rates of interest are compatible with the same market prices of commodities. — But now take another look at this slyness. He hears the correct remark: “But interest is paid for this money?” and this, of course, implies the question: “What has the interest, which the banker receives, who does not deal in commodities at all, to do with these commodities? And do not manufacturers receive money at the same rate of interest, although they invest it in widely different markets, that is, in markets, in which widely different conditions of demand and supply prevail, so far as the commodities used in production are concerned?” And all that this solemn genius has to say in reply to these questions, is that the manufacturer, who buys cotton on credit, pays interest, the measure of which is “The difference between the price for cash payment and the price on credit at the time when payment is due.” Vice versa. The prevailing rate of interest, whose regulation the genius Norman is asked to explain, is the measure of the difference between the cash price and the credit price to the time of due payment. First the cotton is to be sold to its cash price, and this is determined by the market price, which is itself regulated by the condition of supply and demand. Say that the price is 1,000 pounds sterling. This concludes the transaction between the manufacturer and the cotton broker, so far as buying and selling is concerned. Now a second transaction is added. This takes place between the lender and the borrower. The value of 1,000 pounds sterling is advanced to the manufacturer in the shape of cotton, and he has to repay it in money, say, in three months. And the interest for 1,000 pounds sterling, determined by the market rate of interest,

forms the addition over and above the cash price. The price of cotton is determined by supply and demand. But the price of the advance of the value of cotton, of 1,000 pounds sterling for three months, is determined by the rate of interest. And this fact, that the cotton itself is thus transformed into money-capital, proves to Mr. Norman that interest would exist, even if no money existed. If there were no money at all, there would certainly be no general rate of interest.

There is, in the first place, the vulgar conception of capital as “commodities used in production.” So far as these commodities serve as capital, their value as capital compared to their value as commodities is expressed in the profit, which is made out of their productive or mercantile employment. And the rate of profit has under all circumstances something to do with the market price of the bought commodities and their supply and demand, although it is determined besides by circumstances of quite a different kind. And there is no doubt that the rate of interest is generally limited by the rate of profit. But Mr. Norman is precisely asked to tell us how this limit is determined. It is determined by the supply and demand of money-capital as distinguished from the other forms of capital. Now one might ask furthermore: How are the demand and supply of money-capital determined? It is doubtless true, that a tacit connection exists between the supply of commodity-capital and the supply of money-capital, and also that the demand of the industrial capitalist for money-capital is determined by the actual conditions of real production. Instead of giving us information on this point, Norman offers us the sage opinion, that the demand for money-capital is not identical with the demand for money as such, and this wisdom is advanced for no other reason than that behind him. Above Overstone and other Currency prophets always stands the bad conscience, which makes them aware that they are trying to make capital of the mere medium of circulation by the artificial method of legislative interference and to raise the rate of interest.

Now to Lord Overstone, alias Samuel Jones Loyd, who is asked to explain, why he takes 10% for his “money,” because the “capital” in the country is so scarce.

3653. “The fluctuations in the rate of interest arise from one of two causes: From a change in the value of capital” [excellent! Value of capital, generally speaking, signifies precisely the rate of interest! A change in the rate of interest is thus made to arise from a change in the rate of interest.

The phrase ‘value of capital’ never signifies anything else theoretically, as we have shown in another place. Or, if Lord Overstone means the rate of profit by the phrase ‘value of capital,’ then this deep thinker comes back to the position that the rate of interest is regulated by the rate of profit!]” or from a change in the sum of money available in the country. All great fluctuations of the rate of interest, great either in duration or in the extent of the fluctuations, may be clearly traced to changes in the value of capital. There can be no more striking illustration of this fact than the rise of the rate of interest in 1847 and again in the two last years (1855-56); the lesser fluctuations of the rate of interest, which arise from a change in the quantity of the available money, are small in duration and extension. They are frequent, and the more frequent they are, the more effectively they accomplish their purpose.” This purpose is no other than that of making bankers like Overstone rich. Friend Samuel Gurney expresses himself very naively on this point before the Committee of Lords, C. D. 1848. “Are you of the opinion, that the great fluctuations of the rate of interest, which took place last year, were advantageous to the bankers and money brokers, or not?”— “I believe they were advantageous to the money brokers. All fluctuations of business are advantageous to the knowing men.” — 1325. “Should not the banker ultimately lose through the high rate of interest owing to the pauperisation of his best customers?”— “No, Sir, I do not think that this result prevails to any appreciable degree.” — There you can see what talk will do.

We shall recur to the question of the influence of the quantity of available money on the rate of interest later on. But we must note right here that Overstone once again takes one thing for another in this case. The demand for money-capital in 1847 (there was no worry on account of scarcity of money, or the “quantity of available money,” as he called it, before October) increased for various reasons, such as the dearness of corn, rising cotton prices, unsaleable sugars through overproduction, railroad speculation and slumps, overcrowding of foreign markets with cotton goods, the above described forced export to and import from India for the purpose of mere swindling with bills of exchange. All these things, the over-production in industries as well as the underproduction in agriculture, in other words, widely different causes, led to an increased demand for money-capital in the shape of credit and money. The increased demand for money-capital had its causes in the course of the productive process itself.

But whatever may have been the causes, it was the demand for money-capital which brought about the rise in the rate of interest, in the value of money-capital. If Overstone means to say that the value of money-capital rose because it rose, he is simply repeating himself. But if he means by “value of capital” a rise in the rate of profit which caused a rise in the rate of interest, we shall see immediately that this was not the case here. The demand for money-capital, and consequently the “value of capital,” may rise even though the profit may decrease; as soon as the relative supply of money-capital decreases, its “value” increases. Overstone wants to establish the fact that the crisis of 1847, and the high rate of interest going with it, had nothing to do with the “quantity of available money,” that is, with the regulations of the Bank Acts of 1844 which he had inspired; but as a matter of fact this crisis had something to do with these things, so far as the fear of exhausting the bank reserve — a creation of Overstone — added a money panic to the crisis of 1847-48, But this is not the main point here. There was a dearth of money-capital, caused by the excessive volume of operations compared to the available means and brought to an eruption by disturbances in the process of production due to a crop failure, overcapitalisation of railroads, over-production, particularly of cotton goods, swindling practices in the Indian and Chinese business, speculation, superfluous imports of sugar, etc. What the people, who had bought corn at 120 shillings per quarter, lacked when it fell to 60 shillings, were the 60 shillings which they had paid too much and the corresponding credit for that amount in the Lombard advance on corn. It was by no means the lack of bank notes that prevented them from transforming their corn into money at its old price of 120 shillings. The same things applied to those who had bought sugar to such an excess that it became almost unsaleable. It applies likewise to the gentlemen who had tied up their floating capital in railroads and relied on credit to make up for it in their “legitimate” business. To Overstone all this is expressed in “a moral sense of the enhanced value of his money.” But this enhanced value of money-capital had its direct counterpart on the other side in the shape of the depreciated money-value of the real capital (commodity-capital and productive capital). The value of capital in one form rose, because the value of capital in the other forms fell. Overstone, however, seeks to identify these two kinds of value of different sorts of capital in one sole value of capital in general, and he does it by opposing both of them to a scarcity of the medium of circulation, of available money. But the same

amount of money-capital may be loaned with very different quantities of medium of circulation.

Take, for instance, his example of the year 1847. The official bank rate of interest stood at 3 to 3½% in January; 4 to 4½% in February. In March it was generally 4%. April (panic) 4 to 7½%. May 5 to 5½%. June on the whole 5%. July 5%. August 5 to 5½%. September 5% with trifling variations of 5¼, 5½, 6%. October 5, 5½, 7%. November 7 to 10%. December 7 to 5%. — In this case the interest rose, because the profits decreased and the money-values of commodities fell enormously. If Overstone says here that the rate of interest rose in 1847, because the value of capital rose, he cannot mean anything else by “value of capital” but the value of money-capital, and this is precisely the rate of interest and nothing else. But later the cloven hoof appears and the value of capital is identified with the rate of profit.

As for the high rate of interest in 1856, Overstone was indeed ignorant of the fact that this was partially a symptom of the supremacy of credit jobbers, who paid interest, not from their profit, but with the capital of others; he maintained even a few months before the crisis of 1857 that “business is quite sound.”

He testifies furthermore: 3722. “The conception that the business profit is destroyed by raising the rate of interest is highly erroneous. In the first place, a rise in the rate of interest is rarely of long duration; in the second place, if it is of long duration and considerable, it is in the nature of things a rise in the value of capital, and why does the value of capital rise? Because the rate of profit has risen.” — Here, then, we learn at last, what the meaning of “value of capital” is. We remark, by the way, that the rate of profit may hold itself at a high level for a long time, and yet the industrial capitalist’s profit may fall and the rate of interest rise to a point where it swallows the greater portion of the profit.

3724. “The raise of the rate of interest was a result of the enormous expansion of business in our country, and of the great rise in the rate of profit; and if complaint is made, that the raised rate of interest destroys these two things, which were its own cause, it is a logical absurdity, which one does not know how to characterise.” — This is just as logical as though he had said: The increased rate of profit was the result of the raise of prices by speculation, and if complaint is made, that the raise of prices destroys its own cause, namely speculation, it is a logical absurdity, etc. That anything

can ultimately destroy its own cause, is a logical absurdity only for the usurer, who is in love with the high rate of interest. The greatness of the Romans was the cause of their conquests, and their conquests destroyed their greatness. Wealth is the cause of luxury, and luxury has a destructive influence upon wealth. The wiseacre! The idiocy of the present bourgeois world cannot be characterised more markedly than by the respect, which the “logic” of the millionaire, of this dunghill aristocrat, commanded in all England. By the way, even if high profits and an expansion of business may be the cause of a high rate of interest, a high rate of interest is for that reason by no means a cause of high profit. The question is precisely, whether such a high rate of interest (as was seen actually during the crisis) did not continue, or even reach its climax, after the high rate of profit had long gone the way of the flesh.

3718. “As for a great increase of the rate of discount, it is a circumstance, which arises entirely from the increased value of capital, and the cause of this increased value of capital, I believe, may be discovered by every one with perfect clearness. I have already mentioned the fact, that during the 13 years, which this Bank Act was in force, the commerce of England grew from 45 to 120 million pounds. Consider all the events implied by this brief statement in figures, consider the enormous demand for capital, which such a gigantic increase of commerce carries with it, and consider at the same time, the natural source of this great demand, namely the annual savings of the country, have been consumed during the last three or four years by unprofitable expenditures for purposes of war. I confess, I am surprised, that the rate of interest is not much higher; or in other words, I am surprised, that the shortage of capital in consequence of these gigantic operations is not much more stringent, than you have found it to be.”

What a wonderful mixture of words on the part of our logician of usury! Here he is again with his increased value of capital! He seems to imagine, that on one side this enormous expansion of the process of reproduction took place, an accumulation of real capital, and that on the other side a “capital” existed, for which an “enormous demand” arose, in order to accomplish this gigantic increase of commerce! Was not this enormous increase of production itself this increase of capital, and if it created a demand, did it not also create the supply, including an increased supply of money-capital? If the rate of interest rose so high, it did so merely because the demand for money-capital increased still more rapidly than its supply,

which means, in other words, that the expansion of industrial production carried with it a greater volume of its transactions on a credit basis. That is to say, the actual industrial expansion caused an increased demand for “accommodation,” and this last demand is evidently what our banker means by the “enormous demand for capital.” It was surely not the expansion of this mere demand for capital, which raised the export business from 45 to 120 million pounds sterling. And again, what does Overstone mean when he says, that the annual savings of the country swallowed by the Crimean War form the natural source of the supply for this great demand? In the first place, how did England get its accumulations from 1792 to 1815, which was a far greater war than the little Crimean War? In the second place, if the natural source dries up, from what source did capital flow then? It is well known that England did not ask for any loans from foreign countries. But if there is an artificial source aside from the natural one, it would be a very peculiar method for a nation to utilise the natural source in war and the artificial one in business. But if only the old money-capital was available, could it double its effectiveness through a high rate of interest? Mr. Overstone thinks evidently that the annual savings of the country (which were supposed to have been consumed in this case) are converted only into money-capital. But if no real accumulation, that is, no real expansion of production and augmentation of the means of production, took place, what good would the accumulation of debtor’s claims in money on this production do?

The increase in the “value of capital,” which follows from a high rate of profit, is mistaken by Overstone for an increase, which follows from a greater demand for money-capital. This demand may increase for reasons, which are quite independent of the rate of profit. He quotes himself some examples, which show that it rose in 1847 as a result of the depreciation of real capital. He means by the value of capital now real capital now money-capital, just as it may suit his purpose.

The dishonesty of our banking lord, and his narrow minded banker’s point of view, which he aggravates by posing as a schoolmaster, are further revealed by the following: 3728. “You said, that in your opinion the rate of discount is of no particular significance for the merchant; will you kindly state what you regard as an ordinary rate of profit?” — Mr. Overstone declares that it is “impossible” to answer this question. — 3729. “Suppose the average rate of profit to be from 7 to 10%; in that case, a change in the

rate of discount from 2% to 7 or 8% must appreciably affect the rate of profit, must it not?" [This question confounds the rate of industrial profit with the average rate of profit and overlooks the fact, that this last rate of profit is the common source of interest and industrial profit. The rate of interest may leave the average rate of profit untouched, but not the industrial profit.] Overstone replied: "In the first place, business men will not pay a rate of discount, which takes away most of their profits beforehand; they will rather close up their business." [Yes, if they can do so without ruining themselves. So long as their profit is large, they pay the discount, because they are willing, and when profit is low, they pay the discount because they must.] "What does discount mean? Why does a man discount a bill of exchange?...Because he desires to obtain a larger capital." [Hold on! Because he desires to anticipate the return of his tied-up capital in the form of money and to avoid the stopping of business; because he must meet due payments. He demands additional capital only when business is good, or when he speculates on another man's capital, though business may be bad. The discount is by no means a mere device to expand business.] "And why does he wish to obtain command of a greater capital? Because he wants to invest this capital; and why does he want to invest this capital? Because it is profitable; but it would not be profitable for him, if the discount were to swallow his profit."

This self-complacent logician assumes that bills of exchange are discounted only for the purpose of expanding business, and that business is expanded, because it is profitable. The first assumption is wrong. The ordinary business man discounts, in order to anticipate the money-form of his capital and thereby to keep his process of reproduction in flow; not in order to expand his business or secure additional capital, but in order to balance the credit which he gives by the credit which he takes. And if he wants to expand his business on credit, the discounting of bills will do him little good, because it is merely the transformation of capital, which he has already in his hands, from one form into another; he will rather take up a direct loan for a long time. Only the credit swindler will get his fraudulent bills of exchange discounted for the purpose of expanding his business, in order to cover one rotten business by another; not for the purpose of making profits, but of getting possession of the capital of another man.

After Mr. Overstone has thus identified discount with the borrowing of additional capital [instead of identifying it with the transformation of bills

of exchange representing capital into money], he beats at once a retreat, when the thumbscrews are applied to him. — 3730. “Must not merchants, once that they are engaged in business, continue their operations for a certain period of time in spite of a temporary increase in the rate of interest?” — Overstone: “There is no doubt, that in any single transaction, if a man can get hold of capital at a low rate of interest instead of a high rate of interest, taking the matter from this narrow point of view, that it is pleasant for him.” — But it is a very wide point of view, which enables Mr. Overstone now to understand by “capital” all of a sudden only his banker’s capital, and to assume that the man, who discounts a bill of exchange with him, is a man without capital, just because his capital exists in the form of commodities, or because the money-form of his capital is a bill of exchange, which Mr. Overstone converts into another money-form.

3732. “With reference to the Bank Act of 1844, can you state what was the approximate relation of the rate of interest to the gold reserve of the bank; is it true, that, if the gold in the bank amounted to 9 or 10 millions, the rate of interest was 6 or 7%, and when it amounted to 16 millions, the rate of interest was about 3 or 4%?” [The cross-examiner wants to compel him to explain the rate of interest, so far as it is influenced by the amount of gold in the bank, by the rate of interest, so far as it is influenced by the value of capital.]— “I do not say, that this is the case...but if it is, then we should in my opinion resort to still more stringent measures than those of 1844; for if it should be true, that the greater the quantity of gold the lower the rate of interest, then we should go to work, according to this view of the matter, and increase the gold reserve to an unlimited amount, and then we should reduce the rate of interest to zero.” — The cross-examiner Cayley, unmoved by this poor joke, continues: 3733. “If this were so, assuming that 5 millions in gold were returned to the bank, then in the course of the next six months the gold reserve would amount to 16 millions, and assuming that the rate of interest should fall thus to 3 or 4%, how could one maintain, that the fall in the rate of profit was due to a great slump in business?” — “I said the recent great increase in the rate of interest, not the fall in the rate of interest, is intimately connected with the great expansion of business.” — But what Cayley says is this: If a rise of the rate of interest together with a contraction of the gold reserve, is an indication of an expansion of business, then a fall of the rate of interest together with an expansion of the gold

reserve, must be an indication of a contraction of business. Overstone has no answer to this. — 3736. Question: “I note that Your Lordship said that money is an instrument for securing capital.” [This is precisely a mistake, this conception of money as an instrument; it is a form of capital.] “During a decrease of the gold reserve (of the Bank of England) does not the difficulty consist rather in the fact that capitalists cannot get any money?” — Overstone: “No, it is not the capitalists, it is the non-capitalists, who seek to obtain money, in order to carry on the business of people, who are not capitalists.” — Here he declares point blank, that manufacturers and merchants are not capitalists, and that the capital of the capitalist is only money-capital. — 3737. “Are the people who draw bills of exchange no capitalists?” — “The people who draw bills of exchange are probable capitalists and probably not.” — Here he is stuck.

He is then asked, whether the bills of exchange of merchants do not represent the commodities, which they have sold or shipped. He denies, that these bills represent the value of the commodities just exactly as a bank note represents gold. (3740 and 41.) This is a little insolent.

3742. “Is not the purpose of the merchant that of obtaining money?” — “No; to obtain money is not the purpose of drawing a bill of exchange; to obtain money is the purpose of discounting the bill.” — The drawing of bills of exchange is a conversion of commodities into a form of credit-money, just as the discounting of bills of exchange is the conversion of credit-money into other money, namely bank notes. At any rate Mr. Overstone admits here, that the purpose of discounting is to obtain money. A while ago he said that discounting was a means, not of transforming capital from one form into another, but of obtaining additional capital.

3742. “What is the great desire of the business world under the pressure of a panic, such as occurred according to your testimony in 1825, 1837 and 1839; do they want to secure possession of capital or of legal tender money?” — “They want to obtain command of capital, in order to continue their business.” — Their purpose is to obtain means of payment for due bills of exchange on themselves, on account of the prevailing lack of credit, so that they may not have to get rid of their commodities below price. If they have no capital at all themselves, then they receive with the means of payment at the same time capital, because they receive value without giving an equivalent. The desire to obtain money as such consists always in the wish to transform value from the form of commodities or creditor’s claims

into money. Hence also, aside from crisis, the great difference between the borrowing of capital and discount, the last being a mere transformation of money claims from one shape into another, or into real money.

[I take the liberty, in my capacity of editor, to interpolate a few remarks here.]

With Norman as well as Loyd-Overstone the banker always figures as a man, who advances “capital” to others, and his customers appear as people, who demand “capital” from him. Thus Overstone says, that people have bills of exchange discounted through him, “because they wish to obtain capital” , and that it is pleasant for such people to “obtain command of capital” at a “low rate of interest” . “Money is an instrument for obtaining capital” , and during a panic the great desire of the business world is to “obtain command of capital” . All the confusion of Loyd and Overstone notwithstanding they reveal at least the fact that they call the thing, which the banker gives to his customer, capital, and that this is a thing formerly not in the possession of the customer, but advanced to him in addition to the one already in his hands.

The banker has become so well accustomed to figure as the distributor [through loans] of the social capital available in the form of money, that he considers every function, by which he hands out money, as loaning. All the money which he pays out appears to him as a loan. If the money is directly loaned, it is literally true. If it is invested in the discounting of bills, then it is in fact advanced by himself until the bill becomes due. In this way the conception grows upon him that he cannot make any payments without loaning money to somebody. And these are loans, not merely in the sense that every investment of money, which has for its object the taking of interest or profit, is economically considered an advance of money, which the owner of money in his capacity as a private individual makes to himself in his capacity as an entrepreneur. They are loans in the definite sense that the banker loans to his customer a sum of money, which constitutes an addition to the capital already held by him.

It is this conception, which, transferred from the banker’s office to political economy, has created the confusing controversy, whether the thing, which the banker loans to his customer in the shape of cash money, is capital or mere money, medium of circulation or currency. In order to decide this fundamentally simple controversy, we must place ourselves in

the position of a customer of a bank. It depends what this customer wants and receives.

If the bank allows to its customer a loan on his own private credit, without any security on his part, then the matter is clear. He certainly receives in that case an advance of a definite amount in addition to the capital so far invested by him. He receives this advance in the form of money; it is not merely money, but money-capital.

If on the other hand, he receives an advance on depositing securities, etc., then this is money paid to him on condition that he pay it back, but it is not capital. For the securities also represent capital, and at that of a larger amount than the money advance upon them. The recipient of the advance receives less capital-value than he deposits as a security; hence the advance is not additional capital for him. He does not agree to this transaction, because he needs capital — for he has this in his securities — but because he needs money. Therefore we have in this case an advance of money, not of capital.

If the loan is granted by discounting bills, then even the form of an advance disappears. The transaction is then purely one of buying and selling. The bill passes by endorsement into the possession of the bank, while the money passes into the possession of the customer. There is no question of any return payment on either side. If a customer buys with a bill of exchange or some similar instrument of credit cash money, it is no more an advance than it is if he buys cash money with other commodities, such as cotton, iron, corn. Still less can this be called an advance of capital. Every purchase and sale between merchant and merchant transfers capital. But an advance of capital takes place only then, when a bill is a fraudulent one, which does not represent any commodities at all, and no banker will take such a bill, if he is aware of its nature. In the regular discounting business the customer of the bank does not, therefore, receive any advance, either of capital or of money, but he receives money for sold commodities.

The cases, in which the customer demands capital from a bank and receives it are thus very plainly distinguished from those, in which he merely receives an advance of money or buys it from the bank. And since particularly Mr. Loyd Overstone very rarely advanced any funds without collateral [he was the banker of my firm in Manchester] it is very evident that his beautiful descriptions of the great quantities of capital loaned by the

generous bankers to the manufacturers in need of capital are gross inventions.

In chapter XXXII Marx says practically the same thing: “The demand for means of payment is a mere demand for convertibility into money, so far as merchants and producers have good securities to offer; it is a demand for money-capital whenever there is no collateral, so that an advance of means of payment gives to them not only the form of money, but also the equivalent, whatever be its form, with which to make payment.” — And again in chapter XXXIII: “Under a developed system of credit, when the money is concentrated in the hands of the bankers, it is they, at least nominally, who make advances of money. This advance does not refer to the money already in circulation. It is an advance made to circulation, not an advance of capital circulated by it.” — Likewise Mr. Chapman, who ought to know, corroborates this conception of the discounting business: B. C. 1857: “The banker has the bill, the banker has bought the bill.” Evid. Question 5139.

We shall return to this subject in chapter XXVIII. — F. E.] 3744. “Will you kindly describe, what you really mean by the term capital?” — Overstone: “Capital consists of various commodities, by means of which trade is carried on; there is a fixed capital and there is a circulating capital. Your ships, your docks, your wharves are fixed capital, your means of subsistence, your clothes, etc. are circulating capital.”

3745. “Has the drain of gold to foreign countries injurious consequences of England?” — “Not so long as one combines this term with a rational meaning.” [Then follows the old Ricardian theory of money]... “in the natural condition of things the money of the world distributes itself among the various countries of the world in certain proportions; these proportions are such, that with such a distribution [of money] the commerce between any one country on one side and all other countries on the other side is one of mere exchanges; but there are disturbing influences, which affect this distribution from time to time, and when these influences arise, a portion of the money of a given country flows off to other countries.” 3746. “You are now using the term ‘money’. If I understood you correctly on former occasions, you called this a loss of capital.” — “What was it that I called a loss of capital?” — 3747. “The export of gold.” — “No, I did not say that. If you treat gold as capital, then it is doubtless a loss of capital; it is a giving

away of a certain portion of precious metal, of which the world money consists.” — 3748. “Did you not say before that a change in the rate of discount is a mere indication of a change in the value of capital?”— “Yes.” — 3749. “And that the rate of discount in general changes with the gold reserve in the Bank of England?”— “Yes, but I have already stated that the fluctuations of the rate of interest, which arise from a change in the quantity of money” [so this is what he calls the quantity of gold actually existing] “are very significant....”

3750. “Then do you mean to say that a decrease of capital has taken place, when a longer, but still temporary, raise of the discount above the ordinary quotation has taken place?”— “A decrease in a certain sense of the word. The relation between capital and the demand for it has changed; but it may be only through an increased demand, not through a decrease in the quantity of capital.” —

[But capital was for him precisely money or gold, and a little before that he had explained the rise of the rate of interest by a rise of the rate of profit, which was due to an expansion, not to a contraction of business or capital.]

3751. “What kind of capital is it that you have particularly in mind here?”— “That depends entirely on what sort of a capital that every one needs. It is the capital which a nation has at its disposal in order to carry on its business, and if this business is doubled, a great increase must occur in the demand for that capital with which it is to be carried on.” [This shrewd banker doubles first the business and then the demand for capital with which it is to be doubled. He never sees anything else but his customer, who asks Mr. Loyd for more capital by which to double the volume of his business.]— “Capital is like any other commodity;” [but according to Mr. Lloyd capital is nothing else but the totality of commodities] “it changes its price” [that is, the commodities change their price twice, one as commodities and the second time as capital] “according to supply and demand.”

3752. “The fluctuations in the rate of discount are in a general way connected with the fluctuations of the gold reserve in the vaults of the bank. Is this the capital to which you refer?”— “No.” — 3753. “Can you give an example, showing when a great supply of capital was accumulated in the Bank of England and at the same time the rate of discount stood high?”— “In the Bank of England it is not capital that is accumulated, but money.” — 3754. “You testified that the rate of interest depends on the quantity of

capital; will you kindly state, what kind of capital you mean, and whether you can quote an example, where a great supply of gold was held in the bank and at the same time the rate of interest was high?”— “It is very probable” [aha!] “that the accumulation of gold in a bank may coincide with a low rate of interest, because a period of low demand for capital” [namely money-capital; the time to which reference is made here, 1844 and 1845, was a period of prosperity] “is a period, in which naturally the means or instrument, by which capital is commanded, can accumulate.” — 3755. “You think, then, that no connection exists between the rate of discount and the quantity of gold in the bank vaults?”— “A connection may exist, but it is not a connection on principle;” [but his Bank Act of 1844 made it precisely a principle of the Bank of England to regulate the rate of interest by the quantity of gold in its possession] “there may be a coincidence of time,” — 3758. “Do you intend to say that the difficulty of the merchants in this country, during times of scarcity of money due to a high rate of interest consists of obtaining capital, and not in obtaining money?”— “You are throwing together two things, which I do not bring together in this form; the difficulty consists in getting capital, and it also consists in getting money....The difficulty of obtaining money, and the difficulty of obtaining capital, is the same difficulty considered at two different stages of its development.” — Here the fish is caught once more. The first difficulty is to discount a bill of exchange, or to obtain a loan on security of commodities. It is the difficulty of converting capital, or a commercial equivalent for capital, into money. And this difficulty expresses itself, among other things, in a high rate of interest. But after the money has been obtained, in what does the second difficulty consist if it is merely a question of paying, has any one any difficulty in getting rid of his money? And if it is a question of buying, where has any one ever had any difficulty in times of crisis in buying anything? Supposing, for the sake of argument, that this should refer to the specific case of a dearth in corn, cotton, etc., this difficulty should become apparent only in the price of these commodities, not in that of money-capital, that is, not in the rate of interest; but the difficulty, so far as it refers to the price of commodities, is overcome by the fact that our man now has the money to buy them.

3760. “But a higher rate of discount is an increased difficulty of obtaining money, is it not?”— “It is an increased difficulty of obtaining money, but it is not the money, the possession of which is essential; it is

only the form” [and this form brings profits into the pockets of the banker] “in which the increased difficulty of obtaining capital presents itself under the complicated relations of a civilised condition.”

3763. Overstone’s reply: “The banker is the middle man, who receives on one side deposits, and on the other side uses these deposits by entrusting them, in the form of capital, to the hand of persons, who etc.”

Here we have at last what he calls capital. He converts money into capital by “entrusting” it, or, less euphemistically, by loaning it out at interest.

After Mr. Overstone has stated, that a change in the rate of discount is not essentially connected with a change in the quantity of gold reserve in the bank, or in the quantity of available money, but that there is at best only a coincidence in time, he repeats:

3804. “If the money in the country is reduced by export, its value rises, and the Bank of England must adapt itself to this change in the value of money;” [that is, the value of money as capital, in other words, the rate of interest, for the value of money as money, compared with commodities, remains the same] “this is technically expressed by the words, that it raises the rate of interest.”

3819. “I never throw the two together.” Meaning money and capital, for the simple reason, that he never distinguishes them.

3834. “The very large sum, which had to be paid out for the necessary subsistence of the country [for corn in 1847] and which was, indeed, capital.”

3841. “The fluctuations in the rate of discount have doubtless a very close connection to the condition of the gold reserve [of the Bank of England], for the condition of the gold reserve is the indicator of the increase or decrease of the quantity of money existing in a country; and in proportion as the money in a country increases or decreases, the value of money falls or rises, and the bank rate of discount will adapt itself to that.”

— Here, then, he admits what he denied once for all in No. 3755-3842. “There is a close connection between the two.” Meaning between the quantity of gold in the issue department and the reserve of notes in the banking department. Here he explains the change in the rate of interest by the change in the quantity of money. But what he says is wrong. The reserve may decrease, because the circulating money in the country may increase. This is the case, when the public takes more notes and the metal reserve

does not decrease. But in that case the rate of interest rises, because then the banking capital of the Bank of England is limited by the Acts of 1844. But he dare not mention this, since this law provides, that these two departments shall not have anything in common.

3859. “A high rate of profit will always create a great demand for capital; a great demand for capital will raise its value.” — Here, we have at last the connection between a high rate of profit and a demand for capital, as Overstone conceives it. Now, a high rate of profit prevailed in 1844-45, for instance, in the cotton industry, because raw cotton was and remained cheap while the demand for cotton goods was strong. The value of capital [and according to a previous statement Overstone calls capital that which every one needs in his business], in the present case the value of raw cotton, was not increased for the manufacturer. Now the high rate of profit may have induced some cotton manufacturer to take up money for the expansion of his business. Thereby the demand for money-capital rose, and nothing else.

3889. “Gold may be money or not, just as paper may be a bank note or not.”

3896. “Do I understand you correctly, then, that you abandon the statement, which you applied in 1840, to the effect that fluctuations in the circulating notes of the Bank of England should be governed by the fluctuations in the quantity of the gold reserve?” — “I abandon it in so far...that according to the present condition of our knowledge we must add to the circulating notes those other notes, which are deposited in the bank reserve of the Bank of England.” — This is superlative. The arbitrary provision, that the bank may make out as many paper notes as it has gold in the treasury and 14 millions more, implies, of course, that its issue of notes fluctuates with the fluctuations of the gold reserve. But since “the present condition of our knowledge” shows clearly, that the mass of notes, which the bank can manufacture according to this (and which the issue department transfers to the banking department), and which circulating between the two departments of the Bank of England and fluctuate with the fluctuations of its gold reserve, does not determine the circulation of bank notes outside of the walls of the Bank of England, and this last circulation becomes a matter of indifference for the administration of the bank, and the circulation between the two departments of the bank, which shows its difference from the real circulation in the reserve, becomes alone essential. For the outside

world this internal circulation is significant only, because the reserve indicates, how close the bank is getting to the legal maximum of its issue of notes, and how much the customers of the bank can still receive from the banking department.

The following is a brilliant example of Overstone's bad faith:

4243. "Does the quantity of capital fluctuate, in your own opinion, to such an extent from one month to another, that its value is changed thereby in the way that we have observed during the last years in the fluctuations of the rate of discount?"— "The proportion between demand and supply of capital may undoubtedly fluctuate even in short intervals....If France announces to-morrow, that it will take up a very large loan, it will undoubtedly cause at once a great change in the value of money, that is, the value of capital, in England."

4245. "If France announces, that it will suddenly need 30 millions worth of commodities for some purpose or other, a great demand will arise for capital, to use the more scientific and simpler expression,"

4246. "The capital, which France might want to buy with its loan, is one thing; the money, with which France buys this, is another thing; is it the money, which changes its value, or not?"— "We are coming back to the old question, and that, I believe, is better suited for the study room of a scientist than for this committee room." — And with this he retires, but not into the study room.⁸⁵

CHAPTER XXVII. THE ROLE OF CREDIT IN CAPITALIST PRODUCTION.

The general remarks, which the credit system so far elicited from us, were the following:

Its necessary development, for the purpose of procuring the compensation of the rate of profit, or the movements of this compensation, upon which the entire capitalist production rests.

Reduction of the cost of circulation.

One of the principal expenses of the circulation is money itself, so far as it represents value itself. It is economized by credit in three ways.

It is entirely eliminated in a large portion of the transactions.

B. The circulation of the circulating medium is accelerated.⁸⁶ This coincides partly with the statement to be made under 2). On one hand, the acceleration is technical; that is, with the same number and quantity of actual transfers of commodities for consumption, a smaller quantity of money or tokens of money performs the same service. This is connected with the technique of the banking business. On the other hand, credit accelerates the velocity of the circulation of money.

C. Replacement of gold money by paper.

Acceleration, by credit, of the individual phases of circulation or of the metamorphoses of commodities, and with it an acceleration of the process of reproduction in general. (On the other hand credit permits keeping the acts of buying and selling farther apart and thus serves as a basis for speculation.) Contraction of the reserve funds, which may be studied from two sides; on one side as a reduction of the circulating medium, on the other as a reduction of that part of capital, which must always exist in the form of money.⁸⁷

Formation of stock companies. By means of these:

An enormous expansion of the scale of production and enterprises, which were impossible for individual capitals. At the same time such enterprises

as were formerly carried on by governments are socialised.

2) Capital, which rests on a socialised mode of production and presupposes a social concentration of means of production and labor-powers, is here directly endowed with the form of social capital (a capital directly associated individuals) as distinguished from private capital, and its enterprises assume the form of social enterprises as distinguished from individual enterprises. It is the abolition of capital as private property within the boundaries of capitalist production itself.

3) Transformation of the actually functioning capitalist into a mere manager, an administrator of other people's capital, and of the owners of capital into mere owners, mere money-capitalists. Even if the dividends, which they receive, include the interest and profits of enterprise, that is, the total profit (for the salary of the manager is, or is supposed to be, a mere wage of a certain kind of skilled labor, the price of which is regulated in the labor market, like that of any other labor), this total profit is henceforth received only in the form of interest, that is, in the form of a mere compensation of the ownership of capital, which is now separated from its function in the actual process of reproduction in the same way, in which this function, in the person of the manager, is separated from the ownership of capital. The profit now presents itself (and not merely that portion of it, which derives its justification as interest from the profit of the borrower) as a mere appropriation of the surplus-labor of others, arising from the transformation of means of production into capital, that is, from its alienation from its actual producer, from its antagonism as another's property opposed to the individuals actually at work in production, from the manager down to the last day laborer.

In the stock companies the function is separated from the ownership of capital, and labor, of course, is entirely separated from the ownership of means of production and of surplus-labor. This result of the highest development of capitalist production is a necessary transition to the reconversion of capital into the property of the producers, no longer as the private property of individual producers, but as the common property of associates, as social property outright. On the other hand it is a transition to the conversion of all functions in the process of reproduction, which still remain connected with capitalist private property, into mere functions of the associated producers, into social functions.

Before we proceed any further, we call attention to the following fact, which is economically important: Since profit here assumes purely the form of interest, enterprises of this sort may still be successful, if they yield only interest, and this is one of the causes, which stem the fall of the rate of profit, since these enterprises, in which the constant capital is so enormous compared to the variable, do not necessarily come under the regulation of the average rate of profit.

[Since Marx wrote the above, new forms of industrial enterprises have developed, which represent the second and third degree of stock companies. The daily increasing speed, with which production may to-day be intensified on all fields of great industry, is offset on the other hand by the ever increasing slowness, with which the markets for these increased products expand. What the great industries turn out in a few months, can scarcely be absorbed by the markets in years. Add to this the system of protective tariffs, by which every industrial country shuts itself off from all others, particularly from England, and which increases home production still more by artificial means. The results are a chronic overproduction, depressed prices, falling or disappearing profits; in short, the long cherished freedom of competition has reached the end of its tether and is compelled to announce its own palpable bankruptcy. This is shown by the fact, that the great captains of industry of a certain line meet for the joint regulation of production by means of a kartel. A committee determines the quantity to be produced by each establishment and distributes ultimately the incoming orders. In some cases even international kartels were formed temporarily, for instance, one uniting the English and German iron producers. But even this form of socialisation did not suffice. The antagonism of interests between the individual firms broke through the agreement quite frequently and restored competition. This led in some lines, where the scale of production permitted it, to the concentration of the entire production of this line in one great stock company under one joint management. In America this has been accomplished several times; in Europe the greatest illustration is so far the United Alkali Trust, which has brought the entire Alkali production of the British into the hands of one single business firm. The former owners of the individual works, more than thirty, have received the tax value of their entire establishment in shares of stock, totalling about 5 million pounds sterling, which represent the fixed capital of the trust. The technical management remains in the same hands, but the business

management is centralised in the hands of the general management. The floating capital, amounting to about one million pounds, was offered to the public for subscription. The total capital is, therefore, 6 million pounds sterling. In this way competition in this line, which forms the basis of the entire chemical industry, has been replaced in England by monopoly, and the future expropriation of this line by the whole of society, the nation, has been well prepared. — F. E.]

This is the abolition of the capitalist mode of production within capitalist production itself, a self-destructive contradiction, which represents on its face a mere phase of transition to a new form of production. It manifests its contradictory nature by its effects. It establishes a monopoly in certain spheres and thereby challenges the interference of the state. It reproduces a new aristocracy of finance, a new sort of parasites in the shape of promoters, speculators and merely nominal directors; a whole system of swindling and cheating by means of corporation juggling, stock jobbing, and stock speculation. It is private production without the control of private property.

Aside from the stock company business, which represents an abolition of capitalist private industry on the basis of the capitalist system itself and destroys private industry in proportion as it expands and seizes new spheres of production, credit offers to the individual capitalist, or to him who is regarded as a capitalist, absolute command of the capital of others and the property of others, within certain limits, and thereby of the labor of others.⁸⁸ A command of social capital, not individual capital of his own gives him command of social labor. The capital itself, which a man really owns, or is supposed to own by public opinion, becomes purely a basis for the superstructure of credit. This is true particularly of wholesale commerce, through whose hands the greatest portion of the social product passes. All standards of measurement, all excuses which are more or less justified under capitalist production, disappear here. What the speculating wholesale merchant risks is social property, not his own. Equally stale becomes the phrase concerning the origin of capital from saving, for what he demands is precisely that others shall save for him. [In this way all France saved recently one and a half billion francs for the Panama Canal swindlers. In fact the entire Panama swindle is here correctly described, fully twenty years before it happened. — F. E.] The other phrase of the abstention is slapped in the face by his luxury, which now becomes a means

of credit by itself. Conceptions, which still have some meaning on a less developed stage of capitalist production, become quite meaningless here. Both success and failure lead now simultaneously to a centralisation of capital, and thus to an expropriation on the most enormous scale. This expropriation extends here from the direct producers to the smaller and smallest capitalists themselves. It is first the point of departure of the capitalist mode of production; its complete accomplishment is the aim of this production. In the last instance it aims at the expropriation of all individuals from the means of production, which cease with the development of social production to be means of private production and products of private production, and which can henceforth be only means of production in the hands of associated producers, their social property, just as they are social products. However, this expropriation appears under the capitalist system in a contradictory form, as an appropriation of social property by a few; and credit gives to these few more and more the character of pure adventurers. Since property here exists in the form of shares of stock, its movements and transfer become purely a result of gambling at the stock exchange, where the little fish are swallowed by the sharks and the lambs by the wolves. In the stock companies the antagonism against the old form becomes apparent, in which social means of production are private property; but the conversion to the form of shares of stock still remains ensnared in the boundaries of capitalism; hence, instead of overcoming the antagonism between the character of wealth as a social one and as private wealth, the stock companies merely develop it in a new form.

The co-operative factories of the laborers themselves represent within the old form the first beginnings of the new, although they naturally reproduce, and must reproduce, everywhere in their actual organisation all the shortcomings of the prevailing system. But the antagonism between capital and labor is overcome within them, although only in the form of making the associated laborers their own capitalists, that is, enabling them to use the means of production for the employment of their own labor. They show the way, in which a new mode of production may naturally grow out of an old one, when the development of the material forces of production and of the corresponding forms of social production has reached a certain stage. Without the factory system arising out of the capitalist mode of production the co-operative factory could not develop, nor without the credit system arising out of the same mode of production. The credit system

is not only the principal basis for the gradual transformation of capitalist private enterprises into capitalist stock companies, but also a means for the gradual extension of co-operative enterprises on a more or less natural scale. The capitalist stock companies as well as the co-operative factories may be considered as forms of transition from the capitalist mode of production to the associated one, with this distinction, that the antagonism is met negatively in the one, positively in the other.

So far we have considered the development of the credit system, and the latent abolition of capitalist property implied by it, mainly with reference to industrial capital. In the following chapters we shall consider credit with reference to interest-bearing capital as such, both the effect of interest on this capital and the form which it assumes thereby; and on this point we shall have to make a few more specific remarks of economic significance.

For the present we have this to say:

The credit system appears as the main lever of overproduction and overspeculation in commerce solely because the process of reproduction, which is elastic in its nature, is here forced to its extreme limits, and is so forced for the reason that a large part of the social capital is employed by people who do not own it and who push things with far less caution than the owner, who carefully weighs the possibilities of his private capital, which he handles himself. This simply demonstrates the fact, that the production of values by capital based on the antagonistic nature of the capitalist system permits an actual, free, development only up to a certain point, so that it constitutes an immanent fetter and barrier of production, which are continually overstepped by the credit system.⁸⁹ Hence the credit system accelerates the material development of the forces of production and the establishment of the world market. To bring these material foundations of the new mode of production to a certain degree of perfection, is the historical mission of the capitalist system of production. At the same time credit accelerates the violent eruptions of this antagonism, the crises, and thereby the development of the elements of disintegration of the old mode of production.

Two natures, then, are immanent in the credit system. On one side, it develops the incentive of capitalist production, the accumulation of wealth by the appropriation and exploitation of the labor of others, to the purest and most colossal form of gambling and swindling, and reduces more and more the number of those, who exploit the social wealth. On the other side,

it constitutes a transition to a new mode of production . It is this ambiguous nature, which endows the principal spokesmen of credit from Law to Isaac Pereire with the pleasant character of swindlers and prophets.

CHAPTER XXVIII. THE MEDIUM OF CIRCULATION (CURRENCY) AND CAPITAL. TOOKE'S AND FULLARTON'S CONCEPTION.

THE distinction between currency and capital, drawn by Tooke,⁹⁰ Wilson, and others, which indiscriminately confounds the differences between the medium of circulation as money, as money-capital, and as interest-bearing capital (moneyed capital in English parlance), refers to two things.

The currency circulates on the one hand as coin (money), so far as it promotes the expenditure of revenue, in the transactions between the individual consumers and the retail merchants. In this category belong all merchants, who sell to the consumers, that is, the individual consumers as distinguished from the productive consumers or producers. Here money circulates in the function of coin, although it continually replaces capital. A certain portion of the money in a certain country is continually devoted to this function, although this portion consists of perpetually varying pieces of individual coin. On the other hand, so far as money promotes the transfer of capital, either as a means of purchase (means of circulation), or as a means of payment, it is capital. It is, therefore, neither its function as a means of purchase, nor that as a means of payment, which distinguishes it from coin, for it may act as a means of purchase also between dealer and dealer, so far as they buy on cash terms one another, and it may serve as a means of payment also between dealer and consumer, so far as credit is given and the revenue consumed before it is paid. The difference, then, is in fact that between the money-form of revenue and the money-form of capital, but not that between currency and capital, for a certain quantity of money circulates in the transactions between dealers as well as those between consumers and dealers. It is, therefore, equally a currency (circulation) in both functions. In Tooke's conception, confusion is introduced into this question in various ways.

By confounding the definite distinctions of the two functions;

2) By intermingling with it the question of the quantity of money circulating together in both functions;

3) By intermingling with it the question of the relative proportions of the

quantities of currency circulating in the two functions, and thus in the two spheres of the process of reproduction.

Confounding the Definite Distinctions.

Money is said to be currency in the one form, and capital in the other. To the extent that money serves in the one or the other function, be it for the realisation of revenue or the transfer of capital, it performs its duty in buying and selling or in paying, as a means of purchase or payment, and in the wider meaning of the word as currency. The further purposes, to which it is devoted in the accounts of its spender or recipient, who may use it as capital or revenue, do not alter anything in this matter, and this is demonstrated by two facts. Although the kinds of money circulating in the two spheres are different, yet the same price of money, for instance a five pound note, passes from one sphere to the other and performs alternately both functions; this is inevitable for the simple reason, that the retail merchant can give to his capital the form of money which he receives from customers. It may be assumed, that the small change has its center of gravitation in the domain of retail trade; the retail dealer needs it continually to give change and receives it back continually in the payments of his customers. But he also receives money, that is, coin in that metal, which serves as a standard of value, for instance, in England one pound coins, or even bank notes, particularly notes of small denominations, such as five and ten pound notes. These gold coins and notes, with whatever small change he has to spare, are deposited by the retail dealer every day, or every week, in his bank, and he pays for his purchases by drawing checks on his deposits. But the same gold coins and bank notes are continually withdrawn from the bank, indirectly or directly (for instance, small change by manufacturers for the payment of wages), by the entire public in its capacity as consumer, and flow continually back to the retail dealers, for whom they realise in this way a portion of their capital, and at the same time their revenue, again and again. This last circumstance is important, and it is wholly overlooked by Tooke. Only where money is expended as money-capital, in the beginning of the process of reproduction (Book II, Part I), does capital-value exist purely as such. For in the produced commodities there is contained not merely capital, but also surplus-value; they are not capital alone, but also newly produced capital, capital pregnant with the source of revenue. What

the retail dealer gives away for the money returning to him, his commodities, constitutes for him capital plus profit, capital plus revenue.

Furthermore, the circulating small change, when returning to the retail dealer, rehabilitates for him the money-form of his capital.

The difference between circulation as a circulation of revenue and a circulation of capital cannot, therefore, be presented as a difference between currency and capital without creating confusion. This mode of expression is due in the case of Tooke to the fact, that he simply places himself in the position of a banker issuing his own bank notes. The amount of his notes, which is continually in the hands of the public and serves as currency (even if consisting of ever different notes) costs him nothing but paper and printing. They are circulating certificates of indebtedness made out in his own name (bills of exchange), but they bring him money and thus serve as a means of expanding his capital. But they differ from his capital, whether this be his own or borrowed capital. This implies for him a specific distinction between currency and capital, which, however, has nothing to do with the definite definition of terms as such, least of all with those made by Tooke in this case.

The different terms denoting specific functions — whether it be the money form of revenue or of capital — do not change anything in the primal character of money as a medium of circulation; it retains this character, no matter whether it performs the one function or the other. It is true, that money serves more as a medium of circulation in the strict meaning of the term (coin, means of purchase) in its character as the money-form of revenue, on account of the incoherency of the purchases and sales, and because the majority of the spenders of revenue, the laborers, can buy relatively little on credit, while in the transactions of the business world, where the medium of circulation constitutes the money-form of capital, money serves mainly as a means of payment, partly on account of the concentration, partly on account of the prevailing credit system. But the distinction between money as a means of payment and a means of purchase (currency) refers to money itself; it is not a distinction between money and capital. The distinction is not one between currency and capital, merely because more copper and silver circulates in the retail business, and more gold in wholesale business, so that there is a difference between copper and silver on one side, and gold on the other.

Introducing the Question of the Quantity of Money Circulating Together in Both Functions.

To the extent that money circulates, either as a means of purchase or as a means of payment, no matter in which one of the two spheres and independently of its function of realising revenue or capital, the quantity of its circulating mass is regulated by the laws developed previously in the discussion of the simple circulation of commodities, Book I, Chapter III, 2 b. The degree of the velocity of circulation, in other words, the number of repetitions of the same function as means of purchase and payment by the same pieces of money in a given period of time, the mass of simultaneous purchases and sales, or payments, the sum of the prices of the circulating commodities, finally the balances of payments to be spared in the same period, determine in either case the mass of the circulating money, of currency. Whether the money so serving represents capital or revenue for the paying or receiving party, is immaterial, and does not alter the matter in any way. Its mass is simply determined by its function as a medium of purchase and payment.

Introduction of the Question of the Relative Proportions of the Quantities of Currency Circulating in Both Functions and Thus in Both Spheres of the Process of Reproduction.

Both spheres of circulation are connected internally, for on the one hand the mass of the revenues to be spent expresses the volume of consumption, and on the other hand the magnitude of the masses of capital circulating in production and commerce express the volume and velocity of the process of reproduction. Nevertheless the same circumstances have a different effect, working even in opposite directions, upon the quantities of the money circulating in both spheres or functions, or on the quantities of currency, as the English express it in banking parlance. And this gives a new justification for the absurd distinction of Tooke between capital and currency. The fact, that the gentlemen of the Currency Theory confound two different things, is by no means a good reason for making two different conceptions out of this confusion.

In times of prosperity, great expansion, acceleration and intensity of the process of reproduction, the laborers are fully employed. Generally there is also a rise of wages which makes in a slight measure for their fall below the average level in the other periods of the commercial cycle. At the same time the revenue of the capitalists grow considerably. Consumption increases

universally. The prices of commodities also rise regularly, at least in various essential lines of business. Consequently the quantity of the circulating money grows at least within certain limits, since the increasing velocity draws certain barriers around the quantity of the currency. Since that portion of the social revenue, which consists of wages, is originally advanced by the industrial capitalist in the form of variable capital, and always in the form of money, he requires more money in times of prosperity for his circulation. But we must not take this into account twice. We must not count it first as money required for the circulation of the variable capital, and a second time as money required for the circulation of the revenue of the laborers. The money paid to the laborers as wages is spent in retail trade and returns about once a week as a deposit of the retail dealers to the banks, after it has negotiated various intermediary deals in smaller cycles. In times of prosperity the reflux of money proceeds smoothly for the industrial capitalists, and thus the need of money facilities does not increase for the reason that they have to pay more wages, but rather require more money for the circulation of their variable capital.

The final result is, that the mass of currency required for the expenditure of revenue increases decidedly in periods of prosperity.

As for the currency, which is necessary for the transfer of capital for the exclusive use of the capitalists, a period of brisk business is at the same time a period of most elastic and easy credit. The velocity of currency between capitalist and capitalist is regulated directly by credit, and the mass of the currency required for the making of payments and even for cash purchases decreases proportionately. It may increase absolutely, but it decreases under these circumstances relatively, compared to the expansion of the process of reproduction. On the one hand greater amounts of payments are handled without the intervention of any money at all; on the other hand, owing to the great vivacity of the process, the same quantities of money have a greater velocity, both as means of purchase and payment. The same quantity of money promotes the reflux of a greater number of individual capitals.

On the whole, the currency of money in such periods appears full, although its second portion (the transfer of capital) is at least relatively contracted, while its first portion (the expenditure of revenue) is absolutely expanded.

The refluxes express the reconversion of commodity-capital into money, $M - C - M'$, as we have seen in the discussion of the process of reproduction in Volume II, Part I. Credit renders the reflux in the form of money independent of the time of actual reflux, both for the industrial capitalist and the merchant. Both of them sell on credit; their commodities are gotten rid of, before they resume for them the form of money by returning them really in this form. On the other hand they buy on credit, and in this way the value of their commodities is reconverted either into productive capital or commodity-capital even before this value has been transformed into real money, before the price of commodities is due and paid for. In such periods of prosperity the reflux passes off smoothly and easily. The retail dealer pays the wholesale dealer in collateral, the wholesaler pays the manufacturer in the same way, the manufacturer in like manner the importer of the raw material, and so forth. The appearance of rapid and more secure turn-overs maintains itself always for a certain period after they are past in reality, since the turn-overs of credit take the place of the real ones as soon as credit is well under way. The banks begin to scent danger, as soon as their customers deposit more bills of exchange than money. See the above testimony of the Liverpool bank director.

On a previous occasion I have remarked: "In periods of prevailing credit, the rapidity of circulation of money grows faster than the prices of commodities, while in times of declining credit the prices of commodities fall slower than the rapidity of circulation." (Critique of Political Economy, 1859, -136.)

In a period of crisis the condition is reversed. Circulation No. I contracts, prices fall, likewise wages of labor; the number of employed laborers is reduced, the mass of transactions decreases. On the other hand, the need of accommodation in the matter of money increases in circulation No. II in proportion as credit decreases. We shall return to this point immediately.

There is no doubt that, with the decrease of credit which goes with the clogging of the process of reproduction, the mass of circulation No. I required for the expenditure of revenue is contracted, while that of No. II required for the transfer of capital is expanded. But it remains to be analysed, to what extent this statement coincides with the following maintained by Fullarton and others: "A demand for capital on loan and a demand for additional circulation are quite distinct things, and not often found associated." (Fullarton, l. c. , title of chapter 5.)⁹¹

In the first place it is evident, that in the first of the two cases mentioned above, during times of prosperity, when the mass of the circulating medium increases, the demand for it must also increase. But it is likewise evident, that a manufacturer, who draws more or less of his deposit out of a bank in gold or banknotes, because he has more capital to expand in the form of money, does not increase his demand for capital, but merely his demand for this particular form, in which his capital is expended. The demand refers only to the technical form, in which his capital is thrown into circulation. It is well known that a different development of the credit system implies for the same variable capital, or the same quantity of wages, a greater mass of means of circulation (currency) in one country than in another, for instance, more in England than in Scotland, more in Germany than in England. In like manner the same capital invested in agriculture, in the process of reproduction, requires different quantities of money in different seasons for the performance of its function.

But the contrast drawn by Fullarton is not correct. It is by no means the strong demand for loans, as he says, which distinguishes the period of depression from that of prosperity, but the ease with which this demand is satisfied in periods of prosperity, and the difficulties which it meets after a depression has become a fact. It is precisely the enormous development of the credit system during a period of prosperity, hence also the enormous development of the demand for loan capital and the readiness with which the supply meets it in such periods, which brings about a shortage of credit during the period of depression. It is not, therefore, the difference in the size of the demand for loans which characterises both periods.

As we have remarked previously, both periods are primarily distinguished by the fact that in periods of prosperity the demand for currency between consumers and dealers pre-dominates, and in periods of depression that for currency between capitalists. In a period of depression the former decreases, the latter increases.

What appears as the essential mark to Fullarton and others is the phenomenon, that in such periods, in which the securities in the hand of the Bank of England are on the increase, its circulation of notes is decreasing, and vice versa. Now the level of the securities expresses the volume of the pecuniary accommodation, the volume of the discounted bills of exchange and of the advances on marketable collateral. Thus Fullarton says in the

above passage (footnote 91) that the securities in the hands of the Bank of England vary generally in the opposite direction from its circulation of banknotes, and this corroborates the doctrine long held by private banks to the effect that no bank can increase its issue of banknotes beyond a certain point determined by the needs of the public; but if a bank wants to make advances beyond this limit, it must take them out of its capital, that is, it must either realise on securities or utilise deposits which it would otherwise have invested in securities.

This reveals at the same time what Fullarton means by capital. What does capital signify here? It means that the bank can no longer make advances with its own banknotes, promissory notes that cost it nothing, of course. But what does it make payments with in that case? With the sums realised by the sale of securities in reserve, that is, government bonds, stocks, and other interest-bearing papers. And what is this money that it gets in return for the sale of such papers? Gold or banknotes, so far as the last named are legal tender, such as those of the Bank of England. What the bank advances, is under all circumstances money. This money now constitutes a part of its capital. This is evident in the case that it advances gold. If it advances notes, then these notes represent capital, because it has given up some actual value, interest-bearing papers, for them. In the case of private banks the notes secured by them through the sale of securities cannot be anything else, in the main, but notes of the Bank of England or their own notes, since others would hardly be taken in payment for securities. If it is the Bank of England itself, its own notes, which it receives in return, cost it capital, that is, interest-bearing papers. By this means it withdraws its own notes from the circulation. If it reissues these notes, or issues new ones in their stead to the same amount, they represent capital. And they do so equally well, when such notes are used for advances to capitalists, or when they are used later on for investment in securities, as soon as the demand for such pecuniary accommodation decreases. In all these cases the term capital is employed only from the banker's point of view, and it means that the banker is compelled to loan more than his mere credit.

It is well known that the Bank of England makes all its advances in its own notes. Now, if the bank note circulation of this Bank decreases nevertheless in proportion as the discounted bills of exchange and collateral

in its hands, and thus its advances, increase — what becomes of the notes thrown into circulation by it, how do they return to the Bank?

If the demand for money accommodation arises from an unfavorable national balance of trade and implies an export of gold, the matter is very clear. The bills of exchange are discounted in banknotes. The banknotes are exchanged by the bank itself, in its issue department, which issues gold for them, and this gold is exported. It is as though it were to pay out gold directly, without the intervention of notes, on discounting the bills. Such an increased demand, which may amount to from seven to ten million pounds sterling, naturally does not add a single five-pound note to the inland circulation of the country. Now, if it is said, that the Bank of England advances capital in this case, but not currency, it may mean two things. In the first place it may mean, that the bank does not advance credit, but actual values, a part of its own capital, or of capital deposited with it. In the second place it may mean that it does not advance money for inland, but for international circulation. It advances world money, and money for this purpose must always assume the form of a hoard in its metallic body. In this shape money does not merely represent the form of value, but value itself, whose money-form it is. Although this gold represents capital, both for the bank and the exporting money dealer, both financial and commercial capital, yet the demand for it does not come as a demand for capital, but as a demand for the absolute form of money-capital. This demand arises precisely at the moment, when the foreign markets are overcrowded with unsalable English commodity-capital. What is wanted, then, is capital, but not in its capital as capital. What is wanted is capital in the shape of money, in the shape in which money serves as international world money; and this is its original form of precious metal. The exports of gold are not, as Fullarton, Tooke, etc., claim, a mere question of capital. They are a question of money, even if this be money in one specific function. This fact that it is not a question of inland currency, as the advocates of the Currency Theory maintain, does not prove, as Fullarton and others think, that it is a question of mere capital. It is a question of money in the form in which money is an international means of payment. “Whether that capital” (that is, the purchase price for the one million quarters of foreign wheat required after a crop failure in the home country) “is transmitted in merchandise or in specie, is a point which in no way affects the nature of the transaction,” (Fullarton, 1. c.,) but affects essentially the question, whether an export of

gold takes place or not. Capital is transferred in the form of precious metals, because it either cannot be transferred at all in the shape of commodities, or only at a great loss. The fear, which the modern banking system has of gold exports, exceeds anything ever dreamt by the monetary system, which considered precious metals as the only true wealth. Take, for instance, the following cross-examination of the Governor of the Bank of England, Morris, before the Parliamentary Committee on the crisis of 1847-48: Question 3846. “When I speak of the depreciation of stocks and fixed capital, is it not known to you that all capital invested in papers and products of all kinds was depreciated in the same way, that raw materials, cotton, silk, wool, were sent to the continent at the same cut prices, and that sugar, coffee and tea were auctioned off in forced sales.”— “It was inevitable that the nation should make considerable sacrifices, in order to counteract the drain of gold caused by the enormous imports of means of subsistence,” — 3848. “Don’t you believe that it would have been better to touch the eight million pounds sterling stored in the vaults of the bank, instead of trying to recover the gold with such sacrifices?”— “I do not believe that,” — It is gold which here stands for the only true wealth.

Fullarton quotes the discovery of Tooke, that “with only one or two exceptions, and those admitting of satisfactory explanation, every remarkable fall of the exchange, followed by a drain of gold, that has occurred during the last half century, has been coincident throughout with a comparatively low state of the circulating medium, and vice versa.” (Fullarton, p.121). This discovery proves that such drains of gold occur generally after a period of excitement and speculation, as “a signal of a collapse already commenced...an indication of overstocked markets, of a cessation of the foreign demand for our productions, of delayed returns, and, as the necessary sequel of all these, of commercial discredit, manufactories shut up, artisans starving, and a general stagnation of industry and enterprise.” (p.129.) This is at the same time the best rebuttal of the claim of the advocates of the Currency Theory, that a full circulation drives out bullion and a low circulation attracts it. On the other hand, while the Bank of England generally carries a strong gold reserve during a period of prosperity, this hoard is generally formed during the spiritless and stagnating period, which follows after a storm.

All this wisdom concerning the drains of gold, then, amounts to saying that the demand for international media of circulation and payment differs

from the demand for national media of circulation and payment (and this implies the self-evident fact that “the existence of a drain does not necessarily imply any diminution of the internal demand for circulation,” as Fullarton says on page 112 of his work); and that the sending abroad of precious metals and their throwing into international circulation is not identical with the throwing of notes or specie into the internal circulation. For the rest I have shown on a previous occasion, that the movements of a hoard in the shape of a reserve fund for international payments has nothing to do as such with the movements of money as a medium of circulation. It is true that the question is complicated by the fact that the different functions of a hoard, which I have developed from the nature of money, are here placed upon the shoulders of one sole reserve fund, that is, the function of money as a reserve fund for payments of due bills in the interior business; the function of a reserve fund of currency; finally, the function of a reserve fund of world money. It follows from this that under certain circumstances a drain of gold from the Bank to the internal market may be combined with a like drain to the international market. The question is further complicated by the fact that this reserve fund has been loaded with the additional function of serving as a fund for guaranteeing the convertibility of bank notes in countries, in which the credit system and credit money are developed. And on top of all this comes the concentration of the national reserve fund in one single central bank, and, secondly, its reduction to the smallest possible minimum. This explains Fullarton’s plaint (p.143): “One cannot contemplate the perfect silence and facility with which variations of the exchange usually pass off in continental countries, compared with the state of feverish disquiet and alarm always produced in England whenever the treasure in the bank seems to be at all approaching to exhaustion, without being struck with the great advantage in this respect which a metallic currency possesses.”

However, if we leave aside the question of the drain of gold, how can a bank issuing notes, like the Bank of England, increase the amount of the money accommodation granted by it without increasing its issue of bank notes?

So far as the bank itself is concerned, all the notes outside of its walls, whether they circulate or rest in private treasures, are in circulation, that is, not held in its own possession. Hence, if the bank extends its discounting and lombarding business, its advances on securities, all the bank notes

issued for that purpose must flow back to it, for otherwise they would increase the volume of circulation, a thing which is not supposed to happen. This return of notes may take place in two ways.

First: The bank pays to A notes for securities; A pays with these notes for bills of exchange due to B, and B deposits these notes once more in this bank. This closes the circulation of these notes, but the loan remains. (“The loan remains, and the currency, if not wanted, finds its way back to the issuer.” Fullarton, .) The notes, which the bank loaned to A, have now returned to it; but it still remains the creditor of A, or whoever may have been drawn upon by A in discounting his bills, and it remains the debtor of B for the amount of values expressed in these notes, and B thus has a claim upon a corresponding portion of the capital of the bank.

Secondly: A pays to B, and B himself, or C who receives them from B, pays with these notes bills due to the bank, directly or indirectly. In that case the bank is paid in its own notes. This concludes the transaction (excepting the return of this payment by A to the bank).

In what respect, now, shall the loan of the bank to A be regarded as a loan of capital, or as a loan of mere currency?⁹²

[This depends on the nature of the loan itself. Three cases must be distinguished.

First Case. — A receives from the bank the amounts loaned on his own personal credit, without giving any security for them. In this case he does not merely receive means of payment, but also without a doubt some new capital, which he may invest and employ as an additional capital in his business until the day of settlement.

Second Case. — A has given to the bank securities, national bonds, or stocks as collateral, and received for them, say, two-thirds of their value in the shape of a cash loan. In this case he has received means of payment needed by him, but no additional capital, for he entrusted to the bank a larger capital-value than he received from it. But this larger capital-value was, on the one hand, unavailable for the momentary needs of A, because it was invested as interest-bearing capital in a certain form and could not serve as means of payment; on the other hand, A had reasons of his own for not wanting to convert this capital-value directly into means of payment by selling it. His securities served, among other ends, as a reserve capital, and to that end he set them in motion. The transaction between A and the bank, therefore, consists in a mutual transfer of capital, but in such a way, that A

does not receive any additional capital (on the contrary, less capital!) although he receives means of payment which he needs. For the bank, on the other hand, this transaction constitutes a temporary fixation of money-capital in the form of a loan, a conversion of money-capital from one form into another, and this conversion is precisely the essential function of the banking business.

Third Case. — A has had a bill of exchange discounted by the bank, and received its value in cash after the deduction of the discount. In this case he has sold to the bank a money-capital which does not represent ready cash for the same amount in the shape of ready cash. He has sold his running bill for cash money. The bill is now the property of the bank. It does not alter the matter that the last endorser of the bill, A, is responsible to the bank for it in default of payment. He shares this responsibility with the other endorsers and with the first writer of the bill, all of whom are responsible to him. In this case, then, we have not any loan to deal with, but only an ordinary sale and purchase. For this reason A has not to make any return payments to the bank. It covers itself by cashing the bill when it becomes due. Here, also, a transfer of capital has taken place between A and the bank, in exactly the same way, which holds good in the sale and purchase of any other commodity, and for this very reason A did not receive any additional capital. What he needed and received were means of payment, and he received them by having the bank convert one form of his money-capital, his bill, into another, money.

It is only the first case, in which there can be any question of a real loan of capital; in the second and third cases the matter can be so regarded only in the sense that every investment of capital implies an advance of capital. In this sense the bank advances capital to A; but for A it is money-capital at best in the sense that it is a portion of his capital in general. And he does not want and use it as a capital specifically. It is specifically a means of payment for him. Otherwise every ordinary sale of commodities, by which means of payment are secured, might be considered as a loan received. — F. E.]

In the case of private banks issuing notes we have this difference: If its notes remain neither in the local circulation, nor return to it in the form of deposits, or in payment for due bills of exchange, then these notes fall into the hands of people, who compel the private bank to cash these notes in gold or in notes of the Bank of England. In that event its loan represents

indeed an advance of notes of the Bank of England, or, what amounts to the same thing for the private bank, of gold, in other words, of a portion of its banking capital. The same holds good in the case that the Bank of England itself, or some other bank, which has a fixed legal maximum for its issue of notes, must sell securities for the purpose of withdrawing its own notes from circulation and giving them out once more in the shape of loans; in that case the bank's own notes represent a portion of its mobilised banking capital.

Even if the circulation were purely metallic, it would be possible, first, that the drain of gold [Marx evidently refers here to a drain of gold that would, at least partially, go to foreign countries. — F.E.] might empty the treasury, while, secondly, its loans on securities might grow considerably, but flow back to it in the form of deposits, or of payments on due bills of exchange (since the gold is principally demanded from the bank for the payment of balances in the settlement of previous transactions); so that, on one side, the total treasure of the bank would be decreasing with an increase of securities in its hands, while it would be holding the same amount, which it possessed formerly as owner, in the capacity of debtor of its customers, who made deposits, and the total quantity of currency would be decreasing.

Our assumption so far has been, that the loans are made in notes, so that they carry with them a momentary, but immediately disappearing, increase of the issue of notes. But this is not necessary. Instead of paper note, the bank may open a credit account for A, in which case this A, a debtor of the bank, appears in the role of an imaginary depositor. He satisfies his creditors with checks on the bank, and the recipient of these checks passes them on to his own banker, who exchanges them for the checks running against him in the clearing house. In this case no intervention of notes takes place at all, and the entire transaction is confined to the fact that the bank collects its own debt in a check drawn on itself, since its actual recompense consists in its claim on A. In this case the bank has loaned to A a portion of its own banking capital, its own credit to him.

To the extent that this demand for pecuniary accommodation is a demand for capital, it is so only for money-capital. It is capital only from the point of view of the banker, namely gold (in the case of gold exports to foreign countries) or notes of the National Bank, which a private bank can obtain only by purchase against securities, and which, therefore, represent capital for it. Or, again, it is a case of interest-bearing papers, government bonds,

stocks, etc., which must be sold in order to obtain gold or banknotes. Such papers, however, if they are government bonds, are capital only for the buyer, for whom their purchase price represents a capital invested in them. By themselves they are not capital, but merely claims on loans. If they are mortgages, they are mere claims on future ground rent. And if they are shares of stocks, they are mere titles of ownership, which entitle the holder to a share in future surplus-values. All these things are no real capital, they form no constituent parts of capital, nor are they values in themselves. By similar transactions money belonging to the bank may be transformed into deposits, so that the bank, instead of being the owner of this money, owes it to some customer and holds it under a different title of ownership. While this is important as a phenomenon for the bank, yet it does not alter anything in the mass of capital existing in a certain country, or even of money-capital. Capital stands here only for money-capital, and if it is not available in the actual form of money, it stands for a mere title on capital. This is a very important fact, since a scarcity of, and urgent demand for, banking capital is confounded with a decrease of actual capital, which is in such cases rather abundant in the form of means of production and products and swamps the markets.

It is, therefore, easy to explain, how it is that the mass of securities received by a bank as collateral increases, so that the growing demand for pecuniary accommodation can be satisfied by the bank, while the total mass of currency remains the same or decreases. This total mass is held in check during such periods of money stringency in two ways: 1) By a drain of gold; 2) by a demand for money in its capacity of a mere means of payment, when the issued bank notes return immediately, or when the transactions pass off without the intervention of notes by means of book credit; the payments are thus made wholly by a transaction of credit, and the settlement of these payments was the only purpose of this transaction. It is a peculiarity of money, when it serves merely to square balances of payments (and in times of crises loans are taken up for the purpose of paying, not of buying; for the purpose of winding up previous transactions, not of beginning new ones), that its circulation is but small, even where balances are not squared by mere operations of credit, without any intervention of money, so that, when there is a heavy demand for pecuniary accommodation, an enormous quantity of such transactions can take place

without expanding the circulation. But the mere fact, that the circulation of the Bank of England remains stable or decreases simultaneously with a heavy satisfaction of money-accommodation on its part, does not prove without further ceremony, as Fullarton, Tooke and others assume (owing to their mistake to the effect that pecuniary accommodation is identical with taking up capital on loan as additional capital), that the circulation of money (of banknotes) in its function as a means of payment does not increase and extend. While the circulation of notes as means of purchase is decreasing in periods of business depression, when such a heavy accommodation is necessary, their circulation as means of payment may increase, and the aggregate amount of the circulation, the sum of the notes functioning as means of purchase and payment, may remain stable or may even decrease. The currency in its capacity as a means of payment, of banknotes immediately returning to the bank issuing them, is not a currency in the eyes of those economists.

If the circulation as a means of payment were to increase at a higher rate than it decreases as a means of purchase, the aggregate currency would increase, although the money serving in the capacity of a means of purchase would have decreased considerably in quantity. And this actually happens in periods of crisis, when credit collapses completely, so that commodities and securities are unsalable and bills of exchange cannot be discounted, and nothing goes any more but cash money. Since Fullarton and others do not understand, that the circulation of notes as means of payment is the characteristic mark of such periods of money stringency, they treat this phenomenon as accidental. “With respect again to those examples of eager competition for the possession of banknotes, which characterise seasons of panic and which may sometimes, as at the close of 1825, lead to a sudden, though only temporary, enlargement of the issues, even while the efflux of bullion is still going, these, I apprehend, are not to be regarded as among the natural or necessary concomitants of a low exchange; the demand in such cases is not for circulation” (he should say circulation as a means of purchase) “but for hoarding, a demand on the part of alarmed bankers and capitalists which arises generally in the last act of the crisis” (that is, for a reserve of means of payment) “after a long continuation of the drain, and is the precursor of its termination.” (Fullarton, .)

In the discussion of money as a means of payment (Volume I, chapter III, 3 b) we have already explained, in what manner, when the chain of

payments is suddenly interrupted, money turns from its ideal form into a material and at the same time absolute form of value as compared to the commodities. This was illustrated by some examples (footnotes on pages 156 and 157). This interruption itself is partly an effect, partly a cause of the insecurity of credit and of the circumstances accompanying it, such as overcrowding of markets, depreciation of commodities, interruption of production, etc.

But it is evident, that Fullarton transforms the difference between money as a means of purchase and money as a means of payment into the mistaken conception of a difference between currency and capital. This is due to the narrow minded banker's conception of circulation.

It might be asked, finally: What is it that is missing in such periods of stringency, capital or money in its function as a means of payment? And this is a well known controversy.

In the first place, so far as the stringency is marked by a drain of gold, it is evident that what is demanded is the international means of payment. But money in its character of international means of payment is gold in its metallic actuality, as a quantity of values in itself, as a mass of values. It is at the same time capital, capital not as commodity-capital, but as money-capital, capital not in the form of commodities but in the form of money (and at that of money in the eminent meaning of the term, in which it exists as a universal world market commodity). It is not a question of a contrast between a demand for money as a means of payment and a demand for capital. The contrast is rather between capital in its money-form and its commodity-form; and the form which is here demanded and which can alone perform any function here, is its money-form.

Aside from this demand for gold (or silver) it cannot be said that there is a dearth of capital in such periods of crisis. Under extraordinary circumstances, such as a corn famine or a cotton famine, etc., this may be the case; but these are not necessary or regular companions of such periods; and the existence of such a lack of capital cannot be assumed, without further ceremony, from the mere fact, that there is a heavy demand for pecuniary accommodation. On the contrary. The markets are overcrowded and swamped with commodities. Evidently it is not the lack of commodity-capital which causes the stringency. We shall return to this question later.

CHAPTER XXIX. THE COMPOSITION OF BANKING CAPITAL.

IT is now necessary to find out more accurately, what are the constituent elements of banking capital.

We have just seen, that Fullarton and others transform the distinction between money as a means of circulation and money as a means of payment (or eventually as world money, whenever it is a question of gold drains) into a distinction between currency and capital.

The peculiar role played by capital in this instance brought it about, that this banker's economics taught as insistently that money is indeed capital par excellence as the enlightened economics taught that money is not capital.

In subsequent analysis we shall demonstrate, that in such cases money-capital is confounded with moneyed capital in the sense of interest-bearing capital, while in the first named sense money-capital is but a transient form of capital as distinguished from the other forms of capital, commodity-capital and productive capital.

The banking capital consists 1) of cash money, gold or notes; 2) securities. These again may be divided into two parts: Commercial bills, bills of exchange, which run for some time, become due, and the cashing (discounting) of which is the essentially profitable business of the banker; and public securities, such as government bonds, treasury notes, stocks of all kinds, in brief, interest-bearing papers, which are essentially different from bills of exchange. Mortgages may also be classed with this part. The capital composed of these various constituents is again divided into the banker's business capital, and into the deposits, which form his banking capital, or borrowed capital. In the case of banks with an issue of notes these must be counted also. We leave the deposits and notes out of consideration for the present. It is evident, that nothing is altered in the actual constituents of banking capital (money, bills of exchange, deposits), whether these different elements represent the banker's own capital or deposits, the capital of other people. The same division would remain, whether he were to carry on his business with his own capital alone or with no other but deposited capital.

The form of the interest-bearing capital is responsible for the fact, that every determined and regular revenue of money appears as interest on some capital, whether it be due to some capital or not. The money revenue is first converted into interest, and with the interest comes also the capital, from which it is drawn. In like manner every sum of money appears as capital in connection with the interest-bearing capital, as long as it is not spent as revenue; that is, it appears as principal compared to the possible or actual interest which it may yield.

The matter is simple. Let the average rate of interest be 5% annually. A sum of 500 pounds sterling would then yield 25 pounds sterling, if converted into interest-bearing capital. Every fixed annual income of 25 pounds sterling may then be considered as interest on a capital of 500 pounds sterling. This, however, is and remains a purely illusory conception, except the case in which the source of the 25 pounds sterling, whether it be a mere title of ownership or claim of indebtedness, or an actual element of production, such as real estate, is directly transferable or assumes a form, in which it becomes transferable. Let us choose a government debt and wages for an illustration.

The state has to pay to his creditors annually a certain amount of interest for the money loaned from them. In this case the creditor cannot call on the state to give up the principal. He can merely sell his claim, his title of ownership. The capital itself has been consumed, spent by the state. It does not exist any longer. What the creditor of the state possesses is 1) a certificate of indebtedness from the state, amounting, say, to 100 pounds sterling; 2) this certificate gives to the creditor a claim upon the annual revenues of the state, that is, the annual tax revenue, to a certain amount, say, 5 pounds, or 5%; 3) the creditor may sell this certificate at his discretion to some other person. If the rate of interest is 5 %, and the security given by the state is good, the owner A of this certificate can sell it, as a rule, at its value of 100 pounds sterling to B; for it is the same to B, whether he loans 100 pounds sterling at 5 % annually, or whether he secures for himself by the payment of 100 pounds sterling an annual tribute from the state to the amount of 5 pounds sterling. But in all these cases the capital, the progeny of which (interest) is paid by the state, is illusory, fictitious capital. Not only does the amount loaned to the state exist no longer, but it was never intended at all to be invested as capital, and only by investment as capital could it have been transformed into a self-preserving

value. For the original creditor A, the share of interest from taxes falling to him annually represents so much interest on his capital, just as a certain share of the spendthrift's fortune does for the usurer, although in either case the loaned amount was not invested as capital. The possibility of selling his claim on the revenues of the state represents for A the possible return of his principal. As for B, his capital, from his own private point of view, is invested as interest-bearing capital. So far as the transaction is concerned, B has simply taken the place of A by buying the latter's claim on the state's revenue. This transaction may be multiplied ever so often, the capital of the state debt remains a purely fictitious one, and from the moment that the certificates would become unsalable, the fiction of this capital would disappear. Nevertheless this fictitious capital has its own movements, as we shall see presently.

The capital of the national debt appears as a minus, and interest-bearing capital generally is the mother of all crazy forms, so that, for instance, debts may appear in the eyes of the banker as commodities. Now let us look at wages. Wages are here conceived as interest, so that labor-power stands for capital, which yields this interest. For instance, if the wages for one year amount to 50 pounds sterling, and the rate of interest is 5%, the annual labor-power is equal to a capital of 1,000 pounds sterling. The insanity of the capitalist mode of conception reaches its climax here. For instead of explaining the self-expansion of capital out of the exploitation of labor-power, the matter is reversed and the productivity of labor-power itself is this mystic thing, interest-bearing capital. In the second half of the 17th century this used to be a favorite conception (for instance with Petty) but it is used even nowadays in good earnest by vulgar economists and more particularly by German statisticians.⁹³

Unfortunately two disagreeable facts mar this conception. In the first place, the laborer must work, in order to secure this interest. In the second place, he cannot transform the capital-value of his labor-power into cash by transferring it. On the contrary, the annual value of his labor-power is equal to his average annual wages, and his labor has to make good to the seller of his labor-power this same value plus a surplus-value, the increment added by his labor. Under a slave system the laborer has a capital-value, namely his purchase price. And when he is rented out, the renter has to pay, in the first place, the interest on this purchase price, and must furthermore make good the annual wear and tear of the capital.

The forming of a fictitious capital is called capitalising. Every periodically repeated income is capitalised by calculating it on the average rate of interest, as an income which would be realised by a capital at this rate of interest. For instance, if the annual income is 100 pounds sterling and the rate of interest 5%, then these 100 pounds sterling would represent the annual interest on 2,000 pounds sterling, and these 2,000 pounds sterling are regarded as the capital-value of the legal title of ownership upon these 100 pounds sterling annually. For him who buys this title of ownership these 100 pounds sterling of annual income represent indeed the interest on his capital at 5%. All connection with the actual process of self-expansion of capital is thus lost to the last vestige, and the conception of capital as something which expands itself automatically is thereby strengthened.

Even when the certificate of indebtedness — the security — does not represent a purely fictitious capital, as it does in the case of state debts, the capital-value of such papers is nevertheless wholly illusory. We have seen previously in what manner the credit system creates associated capital. The papers are considered as titles of ownership, which represent this capital. The stocks of railroads, mines, navigation companies, and the like, represent actual capital, namely the capital invested and used in such ventures, or the amount of money advanced by the stockholders for the purpose of being used as capital in such ventures. This does not exclude the possibility that they may become victims of swindle. But this capital does not exist twofold, it does not exist as the capital-value of titles of ownership on one side and as the actual capital invested, or to be invested, in those ventures on the other side. It exists only in this last form, and a share of stock is merely a title of ownership on a certain portion of the surplus-value to be realised by it. A may sell this title to B, and B may sell it to C. These transactions do not alter anything in the nature of the case. A or B then have their title in the shape of capital, but C has his capital merely in the shape of a title on the surplus-value to be realised by the stock capital.

The independent movement of the value of these titles of ownership, not only of government bonds but also of stocks, adds weight to the illusion that they constitute a real capital by the side of that capital, or that title, upon which they may have a claim. For they become commodities, whose price has its own peculiar movements and is fixed in its own way. Their market value is determined differently from their nominal value, without any

change in the value of the actual capital, which expands, of course. On the one hand their market value fluctuates with the amount and security of the yields, on which they have a claim. If the nominal value of a share of stock, that is, the invested sum originally represented by this share, is 100 pounds sterling, and the enterprise pays 10%, instead of 5%, then their market-value, other circumstances remaining the same, rises to 200 pounds sterling, so long as the rate of interest is 5%, for when capitalised at 5%, it now represents a fictitious capital of 200 pounds sterling. He who buys it for 200 pounds sterling receives a revenue of 5% on this investment of capital. If the success of the venture is such as to diminish the income from it, the reverse takes place. The market value of these papers is in part fictitious, as it is not determined merely by the actual income, but also by the expected income, which is calculated in advance. But assuming the self-expansion of the actual capital to proceed at a constant rate, or, where no capital exists, as in the case of state debts, the annual income to be fixed by law and otherwise sufficiently secured, the price of such securities rises and falls inversely as the rate of interest. If the rate of interest rises from 5% to 10%, then a security guaranteeing an income of 5 pounds sterling will represent only a capital of 50 pounds sterling. If the rate of interest falls from 5% to 2½%, then the same security will represent a capital of 200 pounds sterling. Its value is always but its capitalised income, that is, its income calculated on a fictitious capital of so many pounds sterling at the prevailing rate of interest. In times when there is a stringency of money on the market these securities will, therefore, fall in price for two reasons: First, because the rate of interest rises, and secondly, because they are thrown in large quantities upon the market for the purpose of getting ready cash. This drop in their price takes place independently of the fact, whether the income guaranteed to their owner by these papers is constant, as it is in the case of government bonds, or whether the self-expansion of the actual capital, which they represent, for instance in industrial enterprises, is subject to interruptions such as interfere with the process of reproduction. In this last eventuality the two causes of depreciation mentioned above are joined by a third one. As soon as the storm is over, the papers rise once more to their former level, unless they represent failures or swindles. Their depreciation in times of crisis serves as a potent means of centralising money.⁹⁴

To the extent that the depreciation or appreciation of such papers is independent of the movements of the value of actual capital represented by

them, the wealth of the nation is just as great before as after their depreciation. "On October 23, 1847, the public funds and the canal and railroad stocks were already depreciated by 114,752,225 pounds sterling." So said Morris, the Governor of the Bank of England, in his testimony before the Committee on Commercial Distress, 1847-48. Unless this depreciation implied an actual stopping of production and of traffic on canals and rails, or a suspension of pending enterprises in the beginning stages, or a throwing away of capital in positively worthless ventures, the nation did not grow poorer by one cent through the bursting of this bubble of fictitious capital.

In all countries of capitalist production, there exists an enormous quantity of so-called interest-bearing capital, or moneyed capital, in this form. And accumulation of money-capital signifies to a large extent nothing else but an accumulation of such claims on production, an accumulation of the market-price, the illusory capital-value, of these claims.

A part of the banking capital is invested in these so-called interest-bearing papers. This is itself a portion of the reserve capital, which does not perform any function in the actual business of banking. The greater portion of these papers consists of bills of exchange, that is, promises to pay made by industrial capitalists or merchants. For the money lender these papers are interest-bearing, in other words, when he buys them, he deducts interest for the time which they still have to run. This is called discounting. It depends on the prevailing rate of interest, how much of a deduction is made from the sum for which the bill calls.

The last part of the capital of a banker consists of his money reserve in gold and notes. The deposits, unless tied up by agreement for a certain time, are always at the disposal of the depositors. They are in a state of continual fluctuation. But while one depositor withdraws his, another brings his in, so that the general average amount of deposits fluctuates little during periods of normal business.

The reserve funds of the banks, in countries with capitalist production, always express on an average the magnitude of the money existing in the shape of a hoard, and a portion of this hoard in its turn consists of papers, mere drafts upon gold, which have no value in themselves. The greater portion of the banking capital is, therefore, purely fictitious and consists of certificates of indebtedness (bills of exchange), government securities (which represent spent capital), and stocks (claims on future yields of

production). And it should not be forgotten, that the money-value of capital represented by these papers in the strongboxes of the banker is itself fictitious, even of those which are checks for guaranteed incomes, such as public bonds, or titles on actual capital, like industrial stocks, and that this value is regulated differently than that of the actual capital, which they represent at least in part; or, when they stand for mere claims on the output of production, and not for capital, that the claim on the same amount is expressed in a continually changing fictitious money-capital. In addition to this it must be noted, that this fictitious capital represents largely, not his own capital, but that of the public, which makes deposits with him, either with or without interest.

Deposits are always made in money, in gold or notes, or in checks upon these. With the exception of the reserve fund, which is contracted or expanded in proportion to the requirements of actual circulation, these deposits are in fact always in the hands, on one side, of the industrial capitalists and merchants, whose bills of exchange are discounted with them, and who receive advances out of them; on the other side, they are in the hands of dealers in securities (exchange brokers), or in the hands of private parties, who have sold their securities, or in the hands of the government (in the case of treasury notes and new loans). The deposits themselves play a double role. On the one hand, as we have just mentioned, they are loaned out as interest-bearing capital and are not found in the cash boxes of the banks, but figure merely in their books as credits of the depositors. On the other hand they figure as such book entries to the extent that the mutual credits of the depositors in the shape of checks on their deposits are balanced against one another and so recorded. In this procedure it is immaterial, whether these deposits are entrusted to the same banker, who can thus balance the various credits against each other, or whether this is done in different banks, who mutually exchange checks and pay only the balances to one another.

With the development of the credit system and of interest-bearing capital all capital seems to double, or even treble, itself by the various modes, in which the same capital, or perhaps the same claim on a debt, appears in different forms in different hands.⁹⁵

The greater portion of this “money-capital” is purely fictitious. All the deposits, with the exception of the reserve fund, are merely credits placed with the banker, which however, never exist in deposit. To the extent that

they serve in the Giro business, they perform the function of capital for the bankers, after these have loaned them out. They pay to one another their mutual checks upon the nonexisting deposits by balancing their mutual accounts.

Adam Smith says justly with regard to the role played by capital in the loaning of money: "Even in the money business the money is merely a check transferring from one hand to another such capitals as are not used by the owners. These capitals may be almost to any amount larger than the amount of money, which serves as an instrument of their transfer. The same pieces of money serve successively in many different loans, likewise in many different purchases. For instance, A lends to W 1,000 pounds sterling, with which W immediately buys from B 1,000 pounds sterling worth of commodities. Since B himself has no immediate use for this money, he lends the identical pieces of money to X, who immediately buys from C commodities worth 1,000 pounds sterling. In the same way and for the same reason C lends this money to Y, who again buys with it commodities from D. In this way the same pieces of gold or paper may serve in the course of a few days in the promotion of three different loans and three different purchases, each one of which has a value equal to the full amount of these pieces. What the three moneyed men, A, B and C have transferred to the three borrowers, W, X and Y, is the power to make these purchases. In this power consists both the value and the usefulness of these loans. The capital loaned out by these three moneyed men is equal to the value of the commodities that can be bought with it, and it is three times greater than the value of the money with which these purchases are made. Nevertheless all these loans may be perfectly safe, since the commodities bought with them by the different debtors are employed in such a way, that they will in time bring an equal value in gold or paper money with a profit to boot. And just as the same pieces of money may serve in the promotion of different loans to an amount exceeding their own value three times, or even thirty times, just so may they serve successively as means of return payment." (Book II, chapter IV.)

Since the same piece of money may perform different purchases, according to the velocity of its circulation, it may just as well perform the service of different loans, for the purchases take it from one hand to another, and a loan is but a transfer from one hand to another without the intervention of a purchase. To every seller his money represents the

changed form of his commodities. Nowadays, when every value is expressed as the value of capital, it represents in the various loans different capitals, and this is but another way of saying that it can realise different commodity-values successively. At the same time it serves as a medium of circulation, in order to transfer the material capitals from hand to hand. In the transaction of loaning it does not pass from hand to hand as a medium of circulation. So long as it remains in the hands of the lender, it is in his hands not a medium of circulation, but the existing value of his capital. And in this form he transfers it when loaning it to another. If A had loaned the money to B, and B to C; without the intervention of purchases, then the same money would not represent three capitals, but only one, only one capital-value. How many capitals it actually represents depends on the number of times in which it performs the service of the embodied value of different commodity-capitals.

The same thing which Adam Smith says of loans in general applies also to deposits, since these are merely another name for loans, which the public gives to the bankers. The same pieces of money may serve as instruments for any number of deposits.

“It is undoubtedly true, that the 1,000 pounds sterling, which some one deposits today with A, are again issued tomorrow and become a deposit with B. The day after, paid away by B, they may form a deposit with C, and so forth infinitely. The same 1,000 pounds sterling may, therefore, by a number of transfers, multiply themselves into an absolutely indeterminable sum of deposits. It is, therefore, possible, that nine-tenths of all the deposits in the United Kingdom have no existence, save for the entries in the books of bankers registering them, who have to square accounts in due time....Such was the case in Scotland, where the currency of money never exceeded 3 million pounds sterling, while the deposits amounted to 27 millions. Unless a general run be made on the banks on account of these deposits, the same 1,000 pounds sterling, traveling backwards, might easily balance an equally indeterminable sum. Since the same 1,000 pounds sterling, with which some one pays today his debt to some dealer, may tomorrow settle this dealer's debt to some merchant, and next day the debt of the merchant to his bank, and so forth without end, the same 1,000 pounds sterling may also wander from hand to hand and from bank to bank, and balance any conceivable amount of deposits.” (The Currency Question Reviewed, p, 163.)

Just as everything is duplicated and triplicated in this credit system and commuted into a mere fiction, so the same applies to the “reserve fund,” where one would at last hope to grasp something solid.

Listen once more to Mr. Morris, the Governor of the Bank of England: “The reserves of the private banks are in the hands of the Bank of England in the form of deposits. The first effects of an export of gold seem to strike only the Bank of England; but it would just as well influence the reserves of the other banks, since it means an export of a part of the reserves, which they have deposited in our bank. In the same way it would influence the reserves of all provincial banks.” (Commercial Distress 1847-48.) Ultimately, then, the reserve funds actually dissolve themselves into the reserve fund of the Bank of England.⁹⁶

However, this reserve fund again has a double existence. The reserve fund of the banking department of the Bank of England is equal to the excess of the notes, which the Bank is authorised to issue, over the notes in circulation. The legal maximum of the note issue is 14 million pounds sterling (for which no metallic reserve is required; it is the approximate amount owed by the state to the Bank) plus the amount of the precious metals in the Bank. If the supply of precious metals in the Bank amounts to 14 million pounds sterling, the Bank can issue 28 millions in notes, and if 20 millions of these are in circulation, the reserve fund of the banking department is 8 million pounds sterling. These 8 million pounds sterling are, in that case, legally the banking capital at the disposal of the Bank, and at the same time the reserve fund for its deposits. If an exportation of gold takes place now, by which the supply of precious metals in the Bank is reduced by 6 millions — notes to this amount must be destroyed at the same time — then the reserve of the banking department would fall from 8 millions to 2 millions. On the one hand, the Bank would raise its rate of interest considerably; on the other hand, the banks having deposits with it, and the other depositors, would observe a large decrease of the reserve fund covering their own credits in the Bank. In 1857 four of the largest stock banks of London threatened to call in their deposits, and thereby bankrupt the banking department, unless the Bank of England would secure a “government script” suspending the Bank Acts of 1844.⁹⁷

In this way the banking department might fail, while a certain number of millions (for instance, 8 millions in 1847) are held in its issue department to

secure the convertibility of its circulating notes. But this security is once more illusory.

“The greater portion of the deposits, for which the bankers themselves have no immediate demand, passes into the hands of the bill brokers, who in return give to the banker security for his loan by means of commercial bills, which they have already discounted for people in London or in the provinces. The bill broker is responsible to the banker for the return payment of this money at call; and these transactions are of such an enormous volume, that Mr. Neave, the present Governor of the Bank of England, said in his testimony: We know that one broker had 5 millions, and we have reason to assume, that another had between 8 and 10 millions; another had 4, another 3½, a third more than 8. I speak of deposits with the brokers.” (Report of Committee on Bank Acts, 1857-58, , section 8.)

“The London bill brokers...carried on their enormous business without any reserve in cash; they relied upon the incomes from the successively due bills, or when it came to the worst, upon their power to secure from the Bank of England loans on depositing bills discounted by them.” — Two firms of bill brokers in London suspended payments in 1847; both resumed business later. In 1857 they suspended again. The liabilities of one of these firms amounted in 1847 in round figures to 2,683,000 pounds sterling with a capital of 180,000 pounds sterling; its liabilities in 1857 were 5,300,000 pounds sterling, while its capital apparently was not more than one-quarter of what it had been in 1847. The liabilities of the other firm were both times between 3 or 4 millions, while its capital amounted to no more than 45,000 pounds sterling. (Ibidem, p. XXI, section 52.)

CHAPTER XXX. MONEY-CAPITAL AND ACTUAL CAPITAL, I.

THE only difficult questions, which we are now approaching in the matter of the credit system, are the following:

First: The accumulation of the money-capital strictly so-called. To what extent is it, and is it not, an indication of an actual accumulation of capital, that is, of reproduction on an enlarged scale? The so-called plethora of capital, an expression used only with reference to the interest-bearing capital, is it only a peculiar way of expressing industrial overproduction, or does it constitute a separate phenomenon alongside of it? Does this plethora, or this excessive supply of money-capital, coincide with the existence of stagnating masses of money (bullion, gold coin and bank notes), so that this superfluity of actual money is an expression and phenomenon of that plethora of loan capital?

Secondly: To what extent does a stringency of money, that is, a scarcity of loan capital, express a real lack of actual capital (commodity-capital and productive capital)? To what extent does it coincide, on the other hand, with a lack of money as such, a lack of currency?

So far as we have hitherto considered the peculiar form of accumulation of money-capital and of money wealth in general, it resolved itself into an accumulation of claims of ownership upon labor. The accumulation of the capital of the national debt has been revealed to mean merely an increase of a class of state creditors, who have the privilege of a first claim upon the revenues.⁹⁸

In these facts, by which even an accumulation of debts may appear as an accumulation of capital, the perfection of the reversal accomplished by the credit system becomes apparent. These certificates of indebtedness, which are issued in place of the originally loaned and long spent capital, these paper duplicates of destroyed capital, serve for their owners as capital to the extent that they are salable commodities and may, therefore, be reconverted into capital.

The titles of ownership upon company business, railroads, mines, etc., are indeed, as we have seen, titles on actual capital. But they do not imply

any control of this capital. It cannot be called in. They merely convey legal titles to a portion of the surplus-value to be produced by it. But these titles become likewise paper duplicates of the actual capital, as though a bill of lading were to acquire a value separate from the cargo and simultaneously with it. They become nominal representatives of a capital that does not exist. For the actual capital exists simultaneously and does not change hands by the transfer of those duplicates. They assume the form of interest-bearing capital, because they not only safeguard a certain income, but also make it possible to secure possession of their capital-value in the shape of a return-payment when sold. To the extent that the accumulation of these papers expresses the accumulation of railroads, mines, steamships, etc., it indicates the expansion of the actual process of reproduction, just as the expansion, say, of a tax list indicates the expansion of the taxed objects, for instance, of movable property. But as duplicates serving themselves as commodities for sale and this circulating as capital-values they are illusory, and their value may fall or rise independently of the value of the actual capital, upon which they represent a claim. Their value, that is, their quotation at the Stock Exchange, necessarily has a tendency to rise with a fall in the rate of interest, so far as this fall, independently of the peculiar movements of money-capital, is due merely to the tendency of the rate of profit to fall; so that this imaginary wealth, which has originally a nominal value for each of its aliquot parts, expands for this reason alone in the course of capitalist production.⁹⁹

Gain and loss through fluctuations in the price of these titles of ownership, and their centralisation in the hands of railroad kings, etc., naturally becomes more and more a matter of gambling, which takes the place of labor as the original method of acquiring capital and also assumes the place of direct force. This sort of imaginary money wealth does not merely constitute a very considerable part of the money wealth of private people, but also of banking capital, as we have already indicated.

In order to settle this point without delay, we mention the idea, that one might also mean by the accumulation of money-capital the accumulation of wealth in the hands of bankers (money lenders by profession), acting as middle men between private money-capitalists on one side and the state, communities, and reproducing borrowers on the other. For the entire vast extension of the credit system, and of all credit in general, is exploited by them as though it were their private capital. These fellows possess capital

and incomes always in the form of money or of direct claims upon money. The accumulation of the wealth of this class may proceed in a direction very different from actual accumulation, but it proves at any rate, that this class pockets a good deal of the real accumulation.

Let us reduce the inquiry to narrower limits. Government bonds, like stocks and other securities of all kinds, are spheres of investment for loanable capital, for capital intended to bear interest. They are forms of loaning such capital. But they are not the loan capital itself, which is invested in them. On the other hand, so far as credit plays a direct role in the process of reproduction: what the industrial capitalist or the merchant need when wishing to have a bill discounted or a loan granted is neither stocks nor government bonds. What they need is money. They pawn or sell those securities, when they cannot secure money in any other way. It is the accumulation of this loan capital, with which we have to deal here, and more particularly of the loanable money-capital. We are not here concerned in the loans of houses, machines, or other fixed capital. Nor are we concerned in loans, which industrials and merchants make to one another in the shape of commodities and within the circle of the process of reproduction. We must, indeed, investigate this point still farther before we proceed. But we are concerned exclusively in loans of money, which are made by bankers, as middle men, to industrials and merchants.

Let us, then, analyse first the commercial credit, that is, the credit which the capitalists engaged in reproduction give to one another. It forms the basis of the credit system. Its representative is the bill of exchange, a certificate of indebtedness whose payment is due at a certain date, a document of deferred payment. Every one gives credit with one hand and takes it with the other. Let us leave aside, for the present, the banking credit, which constitutes another, quite different, element. To the extent that these bills in their turn circulate among the merchants as means of payment, by endorsement from one to another, without the intervention of discount, it is merely a transfer of a claim of indebtedness from A to B, and does not alter anything in the general connection. It merely places one man into the position of another. And even in this case the liquidation may take place without the intervention of money. The spinner A, for instance, has to pay a bill of exchange to the cotton broker B, and he has to pay a bill to the importer C. Now, if C also exports yarn, which happens often enough, he may buy yarn from A on a bill of exchange, and the spinner A may

guarantee the broker B with the broker's own bill paid by C to A, whereby at best a balance may have to be settled. The entire transaction then promotes merely the exchange of cotton and yarn. The exporter represents but the spinner, the cotton broker the cotton planter.

In the cycle of this commercial credit we must note two things:

First: The settlement of these mutual claims of indebtedness depends upon the reflux of capital, that is, of C — M, which is merely deferred. If the spinner has received a bill of exchange from a cotton goods manufacturer, then this manufacturer can pay, when he has sold the cotton goods, which he has on the market. If the corn speculator has made out a bill of exchange on his dealer, then the dealer can pay the money, if the corn has meanwhile been sold at the expected price. These payments, then, depend upon the smooth run of the reproduction, that is, the process of production and consumption. But since the credits are mutual, the solvency of one depends upon the solvency of another; for in making out his bill of exchange every one may have counted either on the reflux of the capital in his own business or on the reflux of the capital in another's business, who has to pay him for a bill of exchange drawn in the meantime. Aside from the prospect of returns, the payment is possible only by means of reserve capital, which the writer of the bill has at his command, in order to meet his obligations in case the returns should be delayed.

Secondly: This credit system does not do away with the necessity of cash payments. For a large portion of the expenses must always be paid in cash, such as wages, taxes etc. Furthermore, capitalist B, who has received from C a bill of exchange in place of cash payment, may have to pay his own due bill to D before the bill of C becomes due, and so he must have ready cash. A rotation of such completeness as that assumed above in the reproduction from cotton planter to cotton spinner and vice versa will be an exception; as a rule reproduction will be infringed at many points. We have seen in the discussion of the process of reproduction, volume II, Part III, that the producers of constant capital exchange partly constant capital among each other. In such a case the bills of exchange may be balanced against one another more or less. The same may be the case in the ascending line of production, where the cotton broker draws on the cotton spinner, the spinner on the manufacturer of cotton goods, the manufacturer on the exporter, the exporter on the importer (who may be an importer of cotton). But the cycle of these transactions is not completed simultaneously, and the series of

claims is not turned around backward in the same way. For instance, the claim of the spinner on the weaver is not settled by the claim of the coal dealer on the machine builder. The spinner never has any counterclaims in his business on the machine manufacturer, because his product, yarn, never enters as an element into the process of reproduction of the machine maker. Such claims must, therefore, be settled by money.

The limits of this commercial credit, considered by itself, are 1), the wealth of the industrials and merchants, that is, their command of reserve capital in case of delayed returns; 2) these returns themselves. These may be delayed in time or the prices of commodities may fall in the meantime or the commodities may become momentarily unsalable through a clogging of the markets. The longer the bill runs, the larger must be the reserve capital, and the greater is the possibility of an infringement or retardation of the returns through a fall of prices or an overstocking of markets. And, furthermore, the returns are so much less secure, the more the original transaction was conditioned upon speculation on the rise or fall of the prices of commodities. But it is evident, that with the development of the productive power of labor, and thus of production on a large scale, 1) the markets expand and move a greater distance from the place of production; 2) that credits must be prolonged in consequence; 3) that the speculative element must thus more and more dominate the transactions. Production on a large scale and for distant markets throws the total product into the hands of commerce; but it is impossible, that the capital of a nation should be doubled in such a way, that commerce by itself would be able to buy up the entire national product with its own capital and to sell it again. Credit is, therefore, indispensable here. Credit must grow in volume with the growing volume of value in production, and it must grow in the matter of time with the increasing distance of the markets. A mutual interaction takes place here. The development of the process of production extends the credit, and credit leads to an extension of industrial and commercial operations.

Looking upon this credit separate from banking credit, it is evident that it grows with an increasing volume of industrial capital itself. Loan capital and industrial capital are here identical. The loaned capitals are commodity-capitals, intended either for ultimate individual consumption, or for the replacement of the constant elements of productive capital. What appears as loan capital in this case is always capital existing in some definite phase of the process of reproduction, but passing through sale and purchase from one

hand to the other, while its equivalent is not paid to the buyer until later at some stipulated time. For instance, the cotton passes into the hands of the spinner in exchange for a bill of exchange, the yarn into the hands of the manufacturer of cotton goods in exchange for another bill, the cotton goods into the hands of the merchant for another bill, from the hands of the merchant into those of the exporter for another bill, from the hands of the exporter for another bill into those of some merchant in India, who sells the goods and buys indigo instead, etc. During this passage from hand to hand the cotton accomplishes its metamorphosis into cotton goods, and the cotton goods are finally transported to India and exchanged for indigo, which is shipped to Europe and enters there into the reproductive process. The various phases of the process of reproduction are here promoted by the credit, without any payment on the part of the spinner for the cotton, on the part of the manufacturer of cotton goods for the yarn, on the part of the merchant for the cotton goods, etc. In the first acts of this process the commodity, cotton, goes through its different phases of production, and this transition is promoted by credit. But as soon as the cotton has received its ultimate form as a commodity, the same commodity-capital passes on through the hands of different merchants, who promote its transportation to distant markets, and the last of the merchants finally sells these commodities to the consumer and buys other commodities in their stead, which passes either into consumption or into the process of reproduction. Here, then, we have to distinguish two sections: In the first, credit promotes the actual successive phases in the production of the same article; in the second, it promotes merely the passage of the finished article from the hands of one merchant into those of another, including its transportation, in other words, the act C — M. Yet the commodity is even here at least in a process of circulation, that is, in a phase of the process of reproduction.

It follows, then, that it is never unemployed capital, which is loaned here, but capital, which must change its form in the hands of its owner and which exists in such a form, that it is merely commodity-capital for him, that is, capital which must be reconverted into its original form, and for the present, at least, into money. It is, therefore, the metamorphosis of the commodity, which is here promoted by credit; not merely C — M, but also M — C and the actual process of reproduction. Much credit within the reproductive cycle does not signify (banker's credit excepted) much unemployed capital, which is offered for loans and looking for profitable

investment. It means rather much employment for capital in the process of reproduction. Credit promotes here, 1) so far as the industrial capitalists are concerned, the transition of industrial capital from one phase into another, the connection of the related and dove-tailing spheres of production; 2) so far as the merchants are concerned, it promotes the transportation and the passage of commodities from one hand to another until their definite sale for money or their exchange for other commodities.

The maximum of credit is here identical with the fullest employment of industrial capital, that is, the utmost exertion of its reproductive power without regard to the limits of consumption. These limits of consumption are extended by the exertions of the process of reproduction itself. On one hand this increases the consumption of revenue on the part of laborers and capitalists, on the other it is identical with an exertion of productive consumption.

So long as the process of reproduction is in flow and the reflux assured, this credit lasts and extends, and its extension is based upon the extension of the process of reproduction itself. As soon as a stoppage takes place, in consequence of delayed returns, overstocked markets, fallen prices, there is a superfluity of industrial capital, but it is in a form, in which it cannot perform its functions. It is a mass of commodity-capital, but it is unsalable. It is a mass of fixed capital, but largely unemployed through the clogging of reproduction. Credit is contracted, 1) because this capital is unemployed, that is, stops in one of its phases of reproduction, not being able to complete its metamorphosis; 2) because confidence in the continuity of the process of reproduction has been shaken; 3) because the demand for this commercial credit decreases. The spinner, who restricts his production and has a mass of unsold yarn in stock, does not need to buy any cotton on credit; the merchant does not need to buy any commodities on credit, because he has more than enough of them.

Hence, if this expansion is disturbed, or even the normal exertion of the process of reproduction infringed, credit also becomes scarce; it is more difficult to get commodities on credit. It is particularly the demand for cash payment and the caution observed toward sales on credit which are characteristic of that phase of the industrial cycle, which follows a crash. In the crisis itself, when every one has things to sell, cannot sell them, and yet must sell them, if he would secure means of payment, it is not the mass of the unemployed and investment seeking capital, but rather the mass of

capital tied up in his process of reproduction, that is greatest just when the lack of credit is most felt (and the rate of discount highest in banking credit). The hitherto invested capital is then, indeed, unemployed, because the process of reproduction lags. Factories are closed, raw materials accumulate, finished products swamp the market as commodities. Nothing is more erroneous, therefore, than to blame a scarcity of productive capital for such a condition. It is precisely at such times that there is a superabundance of productive capital, partly so far as the normal, but temporarily contracted, scale of reproduction is concerned, partly with regard to the paralysed consumption.

Let us suppose that the whole society is composed only of industrial capitalists and wage workers. Let us furthermore make exceptions of fluctuations of prices, which prevent large portions of the total capital from reproducing themselves under average conditions and which, owing to the general interrelations of the entire process of reproduction, such as are developed particularly by credit, must always call forth general stoppages of a transient nature. Let us also make abstraction of the bogus transactions and speculations, which the credit system favors. In that case, a crisis could be explained only by a disproportion of the consumption of the capitalists and the accumulation of their capitals. But as matters stand, the reproduction of the capitals invested in production depends largely upon the consuming power of the non-producing classes; while the consuming power of the laborers is handicapped partly by the laws of wages, partly by the fact that it can be exerted only so long as the laborers can be employed at a profit for the capitalist class. The last cause of all real crises always remains the poverty and restricted consumption of the masses as compared to the tendency of capitalist production to develop the productive forces in such a way, that only the absolute power of consumption of the entire society would be their limit.

A real lack of productive capital, at least among capitalistically developed nations, can be said to exist only in times of general crop failures, either in the principal means of subsistence, or in the principal raw materials of industry.

However, in addition to this commercial credit we have the money credit strictly so-called. The loans of the industrials and merchants among one another go hand in hand with loans made to them by the banker and money lender in the form of money. In the discounting of bills of exchange

the loan is but nominal. A manufacturer sells his product for a bill of exchange and gets this bill discounted at some bill broker's. In reality this broker loans only the credit of his banker, and this banker loans to the broker the money of his depositors, made up of the industrial capitalists and merchants themselves, of drawers of ground rent and other unproductive classes, but also of laborers (in saving banks). In this way every industrial manufacturer and merchant gets around the necessity of keeping a large reserve fund and being dependent upon his actual returns. On the other hand the whole process becomes so complicated, partly by the making of bogus checks, partly by operations with commodities for the mere purpose of writing bills of exchange, that the semblance of a solid business and a smooth run of returns may persist even after returns come in only at the expense of swindled money lenders or swindled producers. Thus the business appears almost too sound just on the eve of a crash. The best proof of this is furnished, for instance, by the Reports on Bank Acts of 1857 and 1858, in which all bank directors, merchants, in short, all the summoned experts, with Lord Overstone at their head, congratulated one another on the prosperity and soundness of business — just one month before the eruption of the crisis of August, 1857. And, queer enough, Tooke in his History of Prices passes through the same illusion as the historian of every crisis. Business is always thoroughly sound and the campaign in full swing, until the collapse suddenly overtakes them.

We revert now to the accumulation of money-capital.

Not every augmentation of loanable capital indicates a real accumulation of capital or expansion of the process of reproduction. This becomes most evident in the phase of the industrial cycle following immediately after a crisis, when loanable capital lies fallow in masses. In such moments, in which the process of production is restricted (production in the English industrial districts was reduced by one-third after the crisis of 1847), prices of commodities at their lowest level, the spirit of enterprise paralysed, the rate of interest is low, and it indicates then merely an increase of loanable capital precisely because the industrial capital has been laid lame. It is quite obvious, that less currency is required, when the prices of commodities have fallen, the number of transactions decreased, and the capital invested in wages contracted; that, on the other hand, additional money is required for the function of world money after the debts to foreign countries have been settled either by the exportation of gold or by bankruptcies; that,

finally, the volume of the business of discounting bills diminishes with the number and amounts of bills of exchange. Hence the demand for loanable capital, either in the form of means of circulation or of means of payment (the investment of new capital being out of the question for a while), decreases and it becomes relatively abundant. At the same time, the supply of loanable capital increases also positively under such circumstances, as we shall see later.

Thus “a reduction of transactions and a great super-abundance of money” prevailed after the crisis of 1847 (Commercial Distress, 1847-48, Evidence No. 1664.) The rate of interest was very low on account of the “almost complete annihilation of commerce and nearly utter absence of a possibility of investing money” (1. c., , Testimony of Hodgson, Director of the Royal Bank of Liverpool). What nonsense those gentlemen concocted (and Hodgson is one of the best of them) in order to explain these facts, may be seen from the following phrase: “The stringency (1847) arose from an actual reduction of the money-capital in the country, caused partly by the necessity of paying for the imports from all quarters of the globe in gold, and partly by the conversion of floating capital into fixed.” How the conversion of circulating capital into fixed capital should reduce the money-capital of a country is unintelligible. For in the case of railroads, e.g., in which capital was mainly invested at that time, neither gold nor paper are used up for viaducts and rails, and the money for the railroad stocks, to the extent that it had been deposited for subscriptions, performed exactly the same functions as any other money deposited in banks and even increased the loanable money-capital temporarily, as shown above. But to the extent that it had been spent for construction, it circulated in the country as a means of circulation and payment. Only so far as fixed capital cannot be exported, so that with the impossibility of its export the available capital secured by returns from exported articles is eliminated, including the returns in bullion or cash, might the money-capital be affected. But English export articles were likewise piled up in masses on the foreign markets without being salable. It is true, the floating capital of the merchants and manufacturers of Manchester, etc., who had tied up a portion of their normal business capital in railroad stocks and were therefore dependent upon loan capital for the continuation of their business, had become fixed, and they had to put up with the consequences. But it would have been the same, if the capital belonging to their business, but withdrawn from it, had

been invested, say, in mines instead of railroads, mining products like iron, coal, copper being themselves floating capital.

The actual reduction of available money-capital through crop failure, corn imports, and gold exports constituted an event that had nothing to do with the railroad swindles.— “Nearly all commercial firms had begun to starve their business more or less, in order to invest the money in railroads.” — The very extensive loans, which were made to railroads by commercial firms, misled the latter to depend far too much through the discounting of bills upon the banks and to carry on the commercial business in this way” (the same Hodgson, 1. c.,). “In Manchester immense losses were sustained through speculation in railroads” (R. Gardner, previously mentioned in volume I chapter XV, 3, c., , American edition, and in other places, Evidence No. 4877, 1. c.).

One of the principal causes of the crisis of 1847 was the colossal overcrowding of the markets and the unbounded swindle in the East Indian trade with commodities. But there were also other circumstances, which bankrupted very rich firms in this line: “They had plenty of means, but these could not be made available. Their entire capital was tied up in real estate in Mauritius, or in indigo and sugar factories. After they had assumed obligations to the tune of 5-600,000 pounds sterling, they had no means at hand to pay their bills of exchange, and finally it was found that, in order to pay their bills, they would have to rely entirely upon credit” (Ch. Turner, great East Indian merchant in Liverpool, No. 730, 1. c.). — See furthermore Gardner, No. 4872, 1. c.: Immediately after the Chinese treaty such great prospects for a tremendous extension of our trade with China were held out to this country, that many large factories were built expressly for this business, for the purpose of manufacturing the cotton goods mainly demanded in the Chinese markets, and these were added to all our already existing factories.” — 4874. “How did this business come out?”— “Most disastrously, so that it defies almost every description; I do not believe, that of all the shipments to China in 1844 and 1845 more than two-thirds of the amount have ever returned; tea being the principal article of return export, and such great prospects having been held out to us, we manufacturers counted without fail on a large reduction of the tea tax.” — And now, naively expressed, comes the characteristic confession of faith of the English manufacturer: “Our trade with a foreign market is not limited by its

capacity of consuming our products, it is rather limited here at home by our capacity of consuming the products, which we receive in return for our industrial products.” (The relatively poor countries, with whom England trades, are supposed to be able to pay for and consume any amount of English products, but unfortunately wealthy England cannot digest the products sent in return.) — 4876. “At first I shipped a few commodities out, and these were sold at a loss of about 15% in the full conviction that the price, at which my agents could buy tea, would yield so large a profit through its sale here, that this loss would be made good; but instead of making a profit, I lost sometimes 25% and even as much as 50%.” — 4877. “Did the manufacturers export for their own account?” — “Principally; the merchants, it seems, saw very soon that they did not make anything, and they encouraged the manufacturers to make consignments rather than to participate in them themselves.” — In 1857, on the other hand, the losses and failures fell mainly upon the merchants, since the manufacturers left to them the task of overcrowding the foreign markets “for their own account.”

An expansion of the money-capital arising from the fact that in consequence of the expansion of the banking business a former private hoard or coin reserve may be converted into loanable capital for a short while, does not indicate a growth of the productive capital any more than the increasing deposits of the London stock banks, as soon as they began to pay interest on deposits. (See the example of Ipswich farther along, where in the course of a few years immediately preceding 1857 the deposits of the capitalist farmers were quadrupled.) So long as the scale of production remains the same, this expansion leads only to an abundance of the loanable money-capital compared to the productive. Hence the rate of interest is low.

After the process of reproduction has again reached that state of prosperity, which precedes that of overexertion, the commercial credit once more arrives at a great expansion, which has then indeed for its “sound” basis a flow of easy returns and more extended production. In this state the rate of interest is still low, although it rises above its minimum. This is in fact the only time, of which it may be said, that a low rate of interest, and consequently a relative abundance, of loanable capital, coincide with a real expansion of industrial capital. The facility and regularity of the returns, together with an extensive commercial credit, secures the supply of loan capital in spite of the increased demand for it, and prevents the level of the rate of interest from rising. Moreover, those knights now appear in large

numbers, who work without any reserve capital, or even without any capital at all and operate wholly on a credit basis. To this is added the great expansion of the fixed capital of all forms, and the inauguration of vast masses of new enterprises of wide scope. The interest now rises to its average level. It arrives once more at its maximum, as soon as the new crisis comes in, when credit suddenly stops, payments are suspended, the process of reproduction is delayed, and a superabundance of industrial capital is unemployed, with the above-mentioned exceptions, while there is an almost absolute lack of loan capital.

On the whole, then, the movements of loan capital, as expressed in the rate of interest, tend in a direction opposite to that of industrial capital. That phase in which a low rate of interest rising just above its minimum coincides with an “improvement” and a growing confidence after a crisis, and particularly that phase, in which the rate of interest reaches its average level, midway between its minimum and maximum, are the only two periods in which an abundance of loan capital is available simultaneously with a great expansion of industrial capital. But at the beginning of the industrial cycle a low rate of interest coincides with a contraction, and at the end of an industrial cycle a high rate of interest coincides with a superabundance, of industrial capital. The low rate of interest, which indicates an “improvement,” shows that commercial credit requires the assistance of banking credit but to a slight degree, because it still stands on its own legs.

The industrial cycle is of such a character, that the same cycle must periodically reproduce itself, once that the first impulse has been given.¹⁰⁰

In the condition of lassitude production sinks below the level, which it had reached in the preceding cycle, and for which the technical basis has now been laid. During prosperity, the middle period, it continues to develop on this basis. In the period of overproduction and swindle it exerts the productive forces to the utmost, even beyond the capitalistic limits of the process of production.

That means of payment are scarce during the period of crisis, goes without saying. The convertibility of bills of exchange has substituted itself for the metamorphosis of commodities themselves, and so much more so at such times, as a portion of the firms operates purely on credit. An ignorant

and mistaken legislation, such as that of 1844-45, may intensify a money crisis. But no manner of bank legislation can abolish a crisis.

In a system of production, in which the entire connection of the process of reproduction rests upon credit, a crisis must obviously occur through a tremendous rush for means of payment, when credit suddenly ceases and nothing but cash payment goes. At first glance, therefore, the whole crisis seems to be merely a credit crisis and money crisis. And in fact it is but a question of the convertibility of bills of exchange into cash money. But the majority of these bills represent actual sales and purchases, and it is the extension of these far beyond the demands of society which is at the bottom of the whole crisis. At the same time an enormous quantity of these bills represents mere swindles, and this becomes apparent now, when they burst. There are furthermore unlucky speculations made with the money of other people. Finally there are commodity-capitals, which have either become depreciated or unsalable or returns that can never more be realized. This entire artificial system of forced expansion of the process of reproduction cannot, of course, be remedied by having some bank, like the Bank of England, give to the swindlers the needed capital in the shape of paper notes and buy up all the depreciated commodities at their old nominal values. Moreover, everything appears turned upside down here, since no real prices and their real basis appear in this paper world, but only bullion, metal coin, notes, bills of exchange, securities. Particularly in the centers, in which the whole money business of the country is crowded together, like London, this reversion becomes apparent; the entire process becomes unintelligible. It is not quite so in the industrial centers.

By the way, we make the following remarks about the superabundance of industrial capital, which shows itself during crises: The commodity-capital is in itself also a money-capital, that is, a definite sum of money expressed in the price of the commodities. As a use-value it is a definite quantity of useful objects, and there is a superfluity of them at the time of the crisis. But as a money-capital in itself, as a potential money-capital, it is subject to continual expansion and contraction. On the eve of a crisis, and during its sway, commodity-capital in its capacity as a potential money-capital is contracted. It represents less money-capital for its owner and his creditors (likewise as a security for bills of exchange and loans), than it did at the time when it was bought and when the discounts and loans made on it were transacted. If this is the meaning of the contention, that the money-

capital of a country is reduced in times of stringency, it is identical with the statement, that the prices of commodities have fallen. Such a collapse of prices merely balances their inflation in preceding periods.

The incomes of the unproductive classes and of those, who live on fixed incomes, remain for the greater part stationary during the inflation of prices going hand in hand with an overproduction and overspeculation. Hence their consuming capacity diminishes relatively, and with it their ability to reproduce that portion of the total reproduction, which should enter normally into consumption. Even though their demand should remain nominally the same, it decreases actually.

With reference to the imports and exports we remark, that all countries become successively implicated in a crisis, and that then it becomes evident, that all of them, with few exceptions, have exported and imported too much, so that there is a balance of payment against all of them. The trouble, therefore, is not with the balance of payment. For instance, England suffers from an export of gold. It has imported too much. But at the same time all other countries are overcrowded with English goods. They have also imported too much, or too much have been imported into them. (There is, indeed, a difference between that country, which exports on credit, and those countries, which export little or nothing on credit. But in that case, these last countries import on credit; and this is not the case only when commodities are sent to them on consignment.) The crisis may first break out in England, in that country which gives most of the credit and takes least of it, because the balance of payment due, which must be squared immediately, is against it, even though the general balance of trade is for it. This is explained partly by the credit which it has granted, partly by the mass of capitals loaned to foreign countries, so that a large quantity of returns come back to it in the shape of commodities, aside from actual trade returns. (However, the crisis broke out sometimes in America, that country in which most of the trade and capital credit is taken from England.) The crash in England, introduced and accompanied by an export of gold, settles England's balance of payment, partly by a bankruptcy of its importers (about which more is said farther on), partly by throwing off a portion of its commodity-capital at cut prices to foreign countries, partly by the sale of foreign securities, the purchase of English securities, etc. Now it is the turn of some other country. The balance of payment was momentarily in its favor. But now the time normally allowed between the balance of payment

and balance of trade has been reduced by the crisis or entirely abolished. All payments are now supposed to be made immediately. The same thing is now repeated here. England now has a return of gold, the other country an export of gold. What appears in one country as excessive imports, appears in the other as excessive exports, and vice versa. But overimports and overexports have taken place in all countries (we are not alluding now to any crop failures, but to a general crisis); that is, there has been a general overproduction, promoted by credit and the inflation of prices that goes with it.

In 1857, the crisis broke out in the United States. An export of gold from England to America followed. But as soon as the inflation in America collapsed, the crisis broke out in England and the gold export went from America to England. The same took place between England and the continent. The balance of payment is in times of general crisis against every nation, at least against every commercially developed nation, but always the one succeeding the other, like firing in squads, as soon as the turn of each comes for making payments. And once the crisis has broken out, say, in England, it compresses the succession of these terms of payment into a very short period. It then becomes evident, that all these nations have simultaneously overexported (and overproduced) and overimported (and overtraded), that prices were inflated in all of them, and credit overdrawn. And the same collapse follows in all of them. The phenomenon of gold exports then shows itself successively in all of them, and proves by this very generality, 1), that the gold exports are but an evidence of a crisis, not its cause; 2), that the succession, in which the gold exports take place in different countries, indicates only the time when their turn has come to settle their affairs, the time when the crisis seizes them and causes an eruption of its latent forces.

It is characteristic for the English economic writers — and the economic literature worth mentioning since 1830 resolves itself mainly into a literature on currency, credit, crisis — that they look upon the exports of precious metals in times of crisis, in spite of the alteration of quotations on bills, merely from the standpoint of England, as a purely national phenomenon, and completely close their eyes against the fact, that all other European banks raise their rate of interest, when their own bank raises its in times of crisis, and that, when the cry of distress over the exports of gold is

raised in their country today, it is taken up in America tomorrow and in Germany and France the day after.

In 1847, “the obligations of England had to be fulfilled” [mostly for corn]. “Unfortunately they were mostly fulfilled by bankruptcies.” [The wealthy England got its breath by bankruptcies in its obligations toward the Continent and America.] “But so far as they were met by bankruptcies, they were fulfilled by the export of precious metals.” (Report of Committee on Bank Acts, 1857.) In other words so far as a crisis is intensified by bank legislation, this legislation is a means of cheating the corn-exporting countries in periods of famine, robbing them first of their corn and then of the money for the corn. A prohibition of the export of corn in such periods and in such countries, which are themselves suffering more or less from stringencies, is, therefore, a very rational measure to thwart the above plan of the Bank of England for “meeting obligations on corn imports by bankruptcies.” It is in that case much better that the corn producers and speculators should lose a portion of their profit for the good of their own country than their capital for the good of England.

It follows from the above, that the commodity-capital largely loses its capacity of representing potential money-capital during a crisis, and during periods of business depression in general. The same is true of fictitious capital, interest-bearing papers, so far as they circulate in the stock exchanges as money-capital. Their price falls with a rise of interest. It falls furthermore through a general lack of credit, which compels their owner to throw them in masses on the market, in order to secure money. It falls, finally, in the case of stocks, partly in consequence of the spurious character of the enterprises which they represent, partly in consequence of a decrease of the revenues, for which they constitute drafts. The fictitious capital is enormously reduced in times of crisis, and with it the power of its owners to loan money on it in the market. However, the reduction of the money denomination of these securities in the stock exchange quotations has nothing to do with the actual capital which they represent, but very much indeed with the solvency of their owners.

CHAPTER XXXI. MONEY-CAPITAL AND ACTUAL CAPITAL. II. (Continued.)

WE have not yet come to the end of the question, to what extent the accumulation of capital in the form of loanable money-capital coincides with the actual accumulation, the expansion of the process of reproduction.

The conversion of money into loanable money-capital is a far simpler matter than the transformation of money into productive capital. But two things should be distinguished here.

- 1). The mere conversion of money into money-capital;
- 2.) The conversion of capital or revenue into money, which is turned into loan capital.

It is only the last named point, which can imply a positive accumulation of loan capital connected with an actual accumulation of industrial capital.

Conversion of Money into Loan Capital.

We have already seen, that an accumulation of loan capital to the point of oversaturation may take place, which is connected with productive accumulation only to the extent that it stands in the opposite proportion to it. This is the case in two phases of the industrial cycle, namely first during the time, when the industrial capital in both its forms of productive and commodity-capital is contracted, that is, at the beginning of the cycle after a crisis; and secondly at the time, when the improvement begins without, however, demanding as yet very much bank credit for commercial capital. In the first case the money-capital, which was formerly employed in production and commerce, appears as unemployed loan capital; in the second case it appears employed to an increasing degree, but at a very low rate of interest, because then the industrial and commercial capitalist prescribes the conditions for the money capitalist. The superabundance of loan capital expresses in the first case a stagnation of industrial capital, and in the second a relative independence of commercial credit from banking credit, based on the fluidity of the returns, a short term of credit, and a preponderance of operations with one's own capital. The speculators, who

count on the credit capital of other people, have not yet appeared upon the field; the people, who work with their own capital, are still far removed from an approximation to operations based purely on credit. In the first named phase the superfluity of loan capital is the direct opposite of the expression of actual accumulation. In the second phase it coincides with a renewed expansion of the process of reproduction, accompanies it, but is not its cause. The superabundance of loan capital is already decreasing, is only a relative one compared to the demand. In both cases the expansion of the actual process of accumulation is promoted by it, since the low interest, which coincides in the first case with low prices, in the second with slowly rising prices, increases that portion of the profit, which is transformed into profits of enterprise. This takes place still more when interest rises to its average level during the height of the period of prosperity, when it has grown, but not in the same proportion as profit.

We have seen, on the other hand, that an accumulation of loan capital may take place without any actual accumulation, by mere technical means, such as an expansion and concentration of the banking system, a saving in the currency reserve, or in the reserve fund of private means of payment, which are then always converted into loan capital for a short time. Although this loan capital, which is also called floating capital for this reason, retains the form of loan capital only for short periods (and discount is supposed to be given for short periods only), it flows continually back and forth. If one withdraws it, another brings it along. The mass of loanable money-capital grows thus quite independently of the actual accumulation (we speak here quite generally of short-lived loans on bills and deposits, not of loans for a number of years).

C. 1857. Question 501. “What do you mean by floating capital?” — Answer of Mr. Weguelin, Governor of the Bank of England: “It is capital available for money loans on short time.”...(502) Notes of the Bank of England...of the provincial banks, and the amount of money existing in the country. — Question: “It does not seem, from the testimony submitted to this Committee, provided you mean by floating capital the active circulation” [of the notes of the Bank of England] “as though there were any very considerable fluctuation in this active circulation?” [But there is a great difference, whether this active circulation is loaned by the money lender or advanced by the reproductive capitalist himself.] Weguelin’s answer: “I include in the floating capital the reserves of the bankers, in

which there is considerable fluctuation.” — That is to say, there is considerable fluctuation in that portion of the deposits, which the bankers have not loaned out again, but which figures as their reserve, and for the greater part also as the reserve of the Bank of England, where they are deposited. Finally the same gentleman says that floating capital is bullion, that is, bullion and hard cash (503). — It is truly wonderful, what a different meaning and different form all economic categories receive in this credit jargon of the money market. Floating capital is there the term for circulating capital, which is, of course, quite another thing, money is capital, bullion is capital, bank notes are currency, capital is a commodity, debts are commodities, and fixed capital is money invested in papers that are salable with difficulty!

“The stock banks of London...have increased their deposits from 8,850,774 pounds sterling in 1847 to 43,100,724 pounds sterling in 1857....The evidences and testimonies placed before this Committee permit the conclusion, that a great part of this immense amount is derived from sources, which were formerly not available for this purpose; and that the custom of opening an account with the banker and depositing money with him has extended to numerous classes, that formerly did not invest their capital(!) in this manner. Mr. Rodwell, President of the Association of Provincial Private Banks” [distinguished from stock banks] “and delegated by it to testify before this Committee, states that in the region of Ipswich this custom has quadrupled of late among the capitalist farmers and small business men of that district; that nearly all farmers, even those paying only 50 pounds sterling of rent annually, now have deposits in banks. The mass of these deposits, of course, finds its way to employment in business, and gravitates particularly toward London, the center of commercial activity, where they are first employed in discounting bills and in making other loans to the customers of London Bankers. But a large portion of them, which the bankers themselves cannot use immediately, pass into the hands of bill brokers, who give to the bankers commercial bills in their stead, which they have already discounted once before for people in London and in the provinces.” (B. C. 1858, .)

In giving loans to the bill broker on bills which this broker has discounted once, the banker practically discounts them again; but in reality very many of these bills have already been rediscounted by the bill broker, and he rediscounts new bills with the very same money, with which the

banker rediscounts the bills of the bill broker. What this leads to is shown by the following passage: “Extensive fictitious credits have been created by accommodation bills and blank credits, and this was very much facilitated by the procedure of the provincial stock banks, that discounted such bills and then had them rediscounted by bill brokers in the London market, and at that solely on the strength of the bank’s credit, without regard to the further quality of the bills.” (L. c.)

Concerning this rediscounting and the help which these purely technical increase of loanable capital lends to credit swindlers, the following extract from the “Economist” is instructive: “During many years capital” [namely loanable money-capital] “accumulated in some districts of the country more rapidly than it could be employed, while in others the means of its investment grew faster than the capital itself. While the bankers in the agricultural districts thus found no opportunity to invest their deposits profitably and safely in their own region, those in the industrial districts and the commercial cities had more demand for capital than they could supply. The effect of these different conditions in the various districts has led in recent years to the rise and startlingly rapid extension of a new class of firms engaged in the distribution of capital, who, although generally called bill brokers, are in reality bankers on the very largest scale. The business of these firms is to assume, for definitely agreed periods and at definitely fixed interest, the surplus-capital of the banks in districts in which it could not be employed, just like the temporarily idle funds of stock companies and great commercial firms, and to loan this money at a higher rate of interest to the banks in districts where capital is more in demand; as a rule by rediscounting the bills of their customers....In this way Lombard Street became the great center, in which the transfer of unemployed capital takes place from one part of the country, where it cannot be usefully employed, to another where it is in demand; and this applies to the different parts of the country as well as to similarly situated individuals. Originally these transactions were almost exclusively limited to borrowing and lending on collateral acceptable to banks. But in proportion as the capital of the country increased rapidly and was more and more economised by the erection of banks, the funds at the disposal of discounting firms became so large that they undertook to make advances, first on dock warrants (storage bills on commodities in docks) and then also on bills of lading representing products that had not even arrived, although sometimes, if not regularly,

bills of exchange had already been drawn against them at the produce brokers. This practice soon changed the entire character of the English business. The facilities thus offered by Lombard Street gave to the produce brokers in Mincing Lane a greatly enforced position; these gave in turn the entire advantage to the importing merchants; these last took so much advantage of it that, whereas 25 years previous a taking of credit on his bills of lading or even his dock warrants would have ruined the credit of a merchant, this practice became so general, that it may be considered as the rule, and no longer, as 25 years ago, as a rare exception. Yea, this system has been extended so far, that large sums have been taken up in Lombard Street on bills of exchange drawn against the still growing crops of distant colonies. The result of such accommodations was, that the import merchants expanded their foreign transactions and tied up their floating capital, with which they had hitherto carried on their business, in the most execrable of investments, colonial estates, over which they could exert little or no control. Thus we see the direct concatenation of credits. The capital of the country, which is collected in our agricultural districts, is laid down in small amounts as deposits in country banks, and centralised for investment in Lombard Street. But it has been utilised, first, for the extension of business in our mining and industrial districts by rediscounting bills on banks there; furthermore also for granting greater accommodations to importers of foreign products by loans on warrants and bills of lading, whereby the 'legitimate' merchants' capital of firms in foreign and colonial business was released and made available for the most abominable kinds of investment in transmarine estates." (Economist, 1847, .)

This is the "beautiful concatenation of credits." The rural depositor imagines to deposit only with his banker, and imagines furthermore that, when his banker lends to others, it is done to private persons whom he knows. He has not the slightest suspicion, that this banker places his deposit at the disposal of some London bill broker, over whose operations neither of them have the slightest control.

How great public enterprises, such as railroads, may momentarily increase the loan capital, owing to the circumstance that the deposited amounts always remain at the disposal of the bankers for a certain time until they are really used, we have already seen.

By the way, the mass of the loan capital is quite different from the quantity of the currency. By the quantity of the currency we mean here the

sum of all bank notes and all hard cash existing and circulating in a country, including the bullion of precious metals. One portion of this quantity forms the reserves of the banks, an ever changing magnitude.

“On November 12, 1857” [the date of the suspension of the Bank Acts of 1844], “the total reserve of the Bank of England, including all branch banks, amounted to only 580,751 pounds sterling; the sum of the deposits amounted at the same time to 22,500,000 pounds sterling, of which nearly 6,500,000 pounds sterling belonged to London bankers.” (B. C., 1858, p. LVII.)

The variations of the rate of interest (aside from those occurring in long periods, or from the difference of the rate of interest in different countries; the first named are conditioned in variations of the general rate of profit, the last named on differences in the rates of profit and on the development of credit) depend upon the supply of loan capital (all other circumstances, state of confidence, etc., being equal,) that is, of the capital loaned in the form of money, hard cash, and notes; this is distinguished from industrial capital, which in the shape of commodities is loaned by means of commercial credit among the agents of reproduction themselves.

However, the mass of this loanable capital is different from and independent of the mass of the circulating money.

If 20 pounds sterling were loaned five times per day, a money-capital of 100 pounds sterling would be loaned, and this would imply at the same time that these 20 pounds sterling would besides have to serve at least four times as means of purchase or payment; for if this were to take place without the intervention of purchase and payment, so that this sum would not represent at least four times the converted form of capital (commodities including labor-power), it would not be a capital of 100 pounds sterling, but only five claims of 20 pounds sterling each.

In countries with a developed credit we may assume, that all money-capital available for loaning exists in the form of deposits with banks and money lenders. This holds good at least for the business in a general way. Moreover, in times of good business, before speculation proper breaks loose, when credit is easy and confidence growing, the greater portion of the functions of circulation is settled by a simple transfer of credit, without the intervention of metal or paper money.

The mere possibility of large amounts of deposits with a relatively small quantity of currency, depends, solely:

Upon the number of purchases and sales, which the same piece of money performs;

2) The number of its return wanderings, in which it goes back to the bankers as a deposit, so that its repeated function as a means of payment and purchase is promoted through its renewed conversion into a deposit. For instance, a small dealer deposits weekly with his banker 100 pounds sterling in money; the banker pays with this a portion of a deposit to a manufacturer; this man in his turn pays it over to some laborers; these pay the small dealer with it, who deposits it again in the bank. The 100 pounds sterling deposited by this dealer have, therefore, served, first, in paying to a manufacturer a portion of his deposit; secondly, in paying some laborers; thirdly, in paying the dealer himself, fourthly, in depositing another portion of the money-capital of the same small dealer; for at the end of twenty weeks, provided that he does not have to draw any of his money out of the bank, he would have deposited 2,000 pounds sterling in the bank by means of the same 100 pounds sterling.

To what extent this money-capital is unemployed, is shown only in the inward and outward movements of the banking reserves. Therefore, Mr. Weguelin, Governor of the Bank of England in 1857, concludes that the gold of the Bank of England is the “only” reserve capital. — 1258. “In my opinion the rate of discount is actually determined by the amount of unemployed capital existing in the country. The amount of unemployed capital is represented by the reserve of the Bank of England, which is in fact a gold reserve. Hence, when gold is exported, the amount of unemployed capital in the country is diminished and the value of the remaining parts is thereby increased.” — 1364. “The gold reserve of the Bank of England is in fact the central reserve, or the cash fund, on the basis of which the entire business of the country is carried on....It is this fund, or this reservoir, upon which the effect of the foreign quotations on 'Change always fall.” (Report on Bank Acts, 1857.)

For the accumulation of the actual, this is, productive and commodity-capital, the statistics of exports and imports furnish a measure. These show always that during the decennial cycles of the period of development of British industry from 1815 to 1870 the maximum of the last time of prosperity always reappears before the crisis, whereupon it rises to a new and far higher maximum.

The actual or declared value of the exported products of Great Britain and Ireland in the prosperous year 1824 was 40,396,300 pounds sterling. The amount of the exports falls thereupon with the crisis of 1825 below this sum and fluctuates between 35 and 39 millions annually. With the return of prosperity in 1834 the amount of exports rises above the former maximum to 41,649,191 pounds sterling, and reaches in 1836 the new maximum of 53,368,571 pounds sterling. In 1837 it falls again to 42 millions, so that the new minimum stands higher than the old maximum, and fluctuates thereupon between 50 and 53 millions. The return of prosperity lifts the amount of exports in 1844 to 58,500,000 pounds sterling, a rise far above the maximum of 1836. In 1845 it reaches 60,111,082 pounds sterling; then it falls to something over 57 millions in 1846, reaches in 1847 almost 59 millions, in 1848 about 53 millions, rises in 1849 to 63,500,000, in 1853 to nearly 99 millions, in 1854 to 97 millions, in 1855 to 94,500,000, in 1856 almost 116 millions, and reaches a maximum of 122 millions in 1857. It falls in 1858 to 116 millions, rises already in 1859 to 130 millions, in 1860 to nearly 136 millions, in 1861 only 125 millions (the new minimum is here again higher than the former maximum), in 1863 to 146,500,000.

Of course, the same thing might be demonstrated in the case of imports, which show the extension of the market; but we are here concerned only in the scale of production. [Of course, this holds good of England only for the time of its actual industrial monopoly; but it applies quite generally to the whole complex of countries with modern great industries, so long as the world market is still expanding. — F. E.]

Conversion of Capital or Revenue into Money that is Transformed into Loan Capital.

We will consider the accumulation of money-capital here in so far as it is not an expression, either of a relaxation in the flow of credit, or of greater economy, whether it be an economy in the actually circulating medium or in the reserve capital of the agents engaged in reproduction.

Aside from these two cases, an accumulation of money-capital may arise through extraordinary imports of gold, such as those of 1852 and 1853 resulting from the output of the new Australian and Californian mines. This gold was deposited in the Bank of England. The depositors took notes instead, which they did not at once redeposit in banks. By this means the circulating medium was unusually increased. (Testimony of Weguelin, B. C. 1857, No. 1329.)

The Bank strove to utilise these deposits by lowering its discount to 2%. The mass of gold accumulated in the Bank rose during six months of 1853 to 22 or 23 millions.

The accumulation of all capitalists lending money naturally takes place always in the form of direct money, whereas we have seen that the actual accumulation of industrial capitalists is accomplished, as a rule, by an increase of the elements of reproductive capital itself. Hence the development of the credit system and the enormous concentration of the money-lending business into the hands of great banks must by itself alone accelerate the accumulation of loanable capital, as a form distinguished from actual accumulation. This rapid development of loan capital is, therefore, a result of actual accumulation, for it is a consequence of the development of the process of reproduction, and the profit that forms the source of accumulation for these money-capitalists is but a deduction from the surplus-value, which the reproductive capitalists filch from production (and it is at the same time a portion of the interest on the savings of others). The loan capital accumulates at the expense of both the industrial and commercial capitalists. We have seen that in the unfavorable phases of the industrial cycle the rate of interest may rise so high, that it temporarily devours the whole profit in particularly handicapped lines of business. At the same time the prices of the public securities and other securities also fall. It is at such times that the money-capitalists buy up these depreciated papers in masses, which soon regain their former level in later phases or rise above it. Then they are sold again and a portion of the money-capital of the public appropriated through them. That portion, which is not sold yields a higher interest, because it was bought below price. But the money-capitalists convert all profits made by them and reconverted into capital first into loanable money-capital. An accumulation of such money-capital, as distinguished from the actual accumulation that is its mother, takes place, obviously, even if we consider only the money-capitalists, bankers, etc., by themselves, that is, an accumulation of this particular class of capitalists. And it must grow with every expansion of the credit system such as goes with the expansion of the process of reproduction.

If the rate of interest is low, then the depreciation of the money-capital falls principally upon the depositors, not upon the banks. Before the development of stock banks three-fourths of all deposits rested in the

English banks without returning any interest. If interest is now paid on them, it amounts to at least 1% less than the current rate of interest.

As for the money accumulation of the other classes of capitalists, we leave aside that portion of it, which is invested in interest-bearing papers and accumulates in this form. We consider merely that portion, which is thrown upon the market as loanable money-capital.

In the first place, we have here that portion of the profit, which is not spent as revenue, but intended for accumulation, yet at the same time not immediately of any use for the industrial capitalists in their own business. This profit exists originally in the form of commodity-capital, a part of whose value it constitutes, and is realised with it in money. Now, if it is not reconverted into the production elements of commodity-capital (we leave out of consideration for the present the merchant, whom we shall have to discuss separately), then it must remain for a while in the form of money. This mass increases with the mass of capital itself, even when the rate of profit declines. That portion, which is to be spent as revenue, is gradually consumed, but forms in the meantime a loan capital of the banker in the form of a deposit. Thus even the growth of that portion of profit, which is spent as revenue, expresses itself in a gradual and continually repeated accumulation of loan capital. The same is true of that other portion, which is intended for accumulation. With the development of the credit system, then, and its organisation, even the increase of revenue, that is, of the consumption of the industrial and commercial capitalists, expresses itself as an accumulation of loan capital. And this holds good of all revenues which are consumed gradually, in other words, of ground rent, wages in their higher form, incomes of unproductive classes, etc. All of them assume for a certain time the form of a money revenue and are, therefore, convertible into deposits and thus into loan capital. All revenue, whether it be intended for consumption or accumulation, so long as it exists in some form of money, is a part of the value of commodity-capital transformed into money, and is, for this reason, an expression and result of the actual accumulation, but not the productive capital itself. When a spinner has exchanged his yarn for cotton, while he has exchanged that portion, which forms his revenue, for money, then the real existence of his industrial capital is the yarn, which has passed into the hands of the weaver or, perhaps, of some private consumer, and this yarn is the existence of both the capital-value and surplus-value contained in it, whether it be intended for

reproduction or consumption. The magnitude of the surplus-value transformed into money depends upon the magnitude of the surplus-value contained in the yarn. But as soon as it has been transformed into money, this money is but the existence of the value of this surplus-value. And as such it becomes an element of loan capital. To this end nothing more is required than that it should be transformed into a deposit, if it had not been loaned out by its owner. But in order to be reconverted into productive capital, it must have reached a certain minimum limit.

CHAPTER XXXII. MONEY-CAPITAL AND ACTUAL CAPITAL. III. (Concluded.)

THE mass of the money thus reconverted into capital is a result of the voluminous process of reproduction, but considered by itself, as loanable money-capital, it is not itself a mass of reproductive capital.

The most important point of our presentation so far is, that the expansion of that part of the revenue which is intended for consumption (leaving out of consideration the laborer, because his revenue is equal to the variable capital) represents itself in the first instance as an accumulation of money-capital. The accumulation of money-capital, therefore, presents a factor, which is essentially different from the actual accumulation of industrial capital; for that portion of the annual product, which is intended for consumption, does not become capital in any way. One portion of it replaces capital, namely the constant capital of the producers of means of consumption, but to the extent that it is actually converted into capital, it exists in the natural form of the revenue of the producers of this constant capital. The same money, which represents the revenue and serves merely for the promotion of consumption, is regularly transformed into loanable money-capital, for a certain time. So far as this money represents wages, it is at the same time the money-form of the variable capital; and so far as it replaces the constant capital of the producers of means of consumption, it is the money-form temporarily assumed by their constant capital and serves for the purchase of the natural elements of the constant capital to be replaced by them. Neither in the one nor in the other form does it express in itself any accumulation, although its mass increases with the volume of the process of reproduction. But it performs temporarily the function of loanable money, of money-capital. In this respect the accumulation of money-capital must reflect a greater accumulation of capital than is actually existing, owing to the fact that the extension of individual consumption, being promoted by money, appears as an accumulation of money-capital, whereby it furnishes the money-form for the actual accumulation of money opening new investments of capital.

The accumulation of money, then, expresses in part nothing else but the fact that all money, into which the industrial capital is transformed in the

course of its cycle, assumes the form, not of money advanced by the reproductive capitalists, but of money borrowed by them; so that indeed the advance of money necessary in the process of reproduction appears as an advance of borrowed money. On the basis of commercial credit one capitalist loans indeed to another the money required for the process of reproduction. But this assumes now the form of a transaction, in which the banker, who receives the money as a loan from one portion of the reproductive capitalists, lends it to another portion of these reproductive capitalists, so that the banker appears in the role of a dispenser of blessings; at the same time the disposition of this capital drifts wholly into the hands of the banker in his capacity as a middleman.

A few special forms of accumulation of money-capital still remain to be mentioned. Capital is released, for instance, by a fall in the price of the elements of production, raw materials, etc. If the industrial capitalist cannot expand his process of reproduction immediately, then a portion of his money-capital is expelled from the cycle as superfluous and converted into loanable money-capital. In the second place, capital in the form of money is released especially by the merchant, whenever any interruption of his business takes place. If the merchant has disposed of a series of transactions and cannot begin a new series on account of such interruptions until later, then his realised money represents for him but a hoard, superfluous capital. But at the same time it represents directly an accumulation of loanable money-capital. In the first case, the accumulation of money-capital expresses a repetition of the process of reproduction under more favorable conditions, an actual release of a portion of formerly tied up capital, in other words, an opportunity for expanding the process of reproduction with the same amount of money. But in the other case it expresses merely an interruption in the flow of transactions. However, in both cases it is converted into loanable money-capital, represents its accumulation, influences equally the money-market and the rate of interest, although it expresses a promotion of the accumulation in the actual process in one case and its obstruction in the other. Finally an accumulation of money-capital is brought about by that section of people, who have made their little pile and have withdrawn from reproduction. In proportion as more profits are made in the course of the industrial cycle, their number increases. In their case the accumulation of loanable money-capital expresses on the one hand an actual accumulation (considering its relative volume), and on the other hand

the extent of the transformation of industrial capitalists into mere money-capitalists.

As for the other portion of profit, which is not intended to be consumed as revenue, it is converted into money-capital only when it is not immediately able to find a place for investment in the expansion of the productive sphere in which it has been made. This may be due to two causes. Either the sphere of production may be saturated with capital. Or it may be because accumulation must first have reached a certain volume, before it can serve as capital, according to the proportions of the investment of new capital required in this particular sphere. Hence it is converted for a while into loanable money-capital and serves in the expansion of production in other spheres. Assuming all other circumstances to remain unaltered, the mass of profits required for reconversion into capital will depend on the mass of profits made and thus on the extension of the process of reproduction itself. But if this new accumulation meets with difficulties in its employment, through a lack of spheres for investment, due to the overcrowding of the lines of production and an oversupply of loan capital, then such a plethora of loanable money-capital proves merely that capitalist production has its limits. The subsequent swindle with credit proves, that no positive obstacle stands in the way of the employment of this superfluous capital. The obstacle is merely one immanent in its laws of self-expansion, namely the limits in which capital can expand itself as such. A plethora of money-capital does not necessarily indicate an overproduction, nor even a lack of spheres of investment for capital.

The accumulation of loan-capital consists simply in the fact that money is precipitated as loanable money. This process is very different from an actual transformation into capital; it is merely the accumulation of money in a form, in which it may be invested as capital. But this accumulation may, as we have shown, indicate facts, which are greatly different from actual accumulation. So long as actual accumulation is continually expanding, this extended accumulation of money-capital may be partly its result, partly the result of circumstances, which accompany it but are quite different from it, partly also the result of impediments to actual accumulation. Since accumulation of loan-capital is swelled by such circumstances, which are independent of actual accumulation but nevertheless accompany it, there must be a plethora of money-capital in definite phases of the cycle for this reason alone, if for no other, and this plethora must develop with the

organisation of credit. And simultaneously with it must also develop the necessity of driving the process of production beyond its capitalistic limits, by overproduction, excessive commerce, extreme credit. And this must take place in forms that call forth a reaction.

So far as accumulation of money-capital from ground rent, wages, etc., is concerned, it is superfluous to discuss that here. Only one thing must be mentioned, namely that the business of actual saving and abstinence (by people forming hoards), to the extent that it furnishes elements of accumulation, is left in the division of labor, which comes with the progress of capitalist production, to those who receive the smallest share of such elements, and who frequently enough lose even their savings, as do the laborers when banks fail. On the one hand the capital of the industrial capitalist is not “saved” by himself, but he has command of the savings of others in proportion to the magnitude of his capital; on the other hand the money-capitalist makes of the savings of others his own capital, and of the credit, which the reproductive capitalists give to one another, and which the public gives to them, a source for enriching himself. The last illusion of the capitalist system, to the effect that capital is the fruit of ones own labor and saving, is thereby destroyed. Not only does profit consist of the appropriation of other people’s labor, but the capital, with which this labor of others is set in motion and exploited, consists of other people’s property, which the money-capitalist places at the disposal of the industrial capitalist, at the same time exploiting the latter in his turn.

A few remarks remain to be made about credit-capital.

How often the same piece of money may figure as a loan capital, depends, as we have previously indicated.

On the question, how often it realises the value of commodities by sale or purchase, thereby transferring capital, and furthermore on the question, how often it realises revenue. How often it gets into other hands as a realised value, either of capital or of revenue, depends, therefore, obviously, upon the volume and mass of the actual transactions;

2) On the economy of payments and on the development and organisation of credit-system;

3) On the concatenation and velocity of action of the credits, so that a deposit set down at one point starts off immediately as a loan at another.

Even assuming that the form, in which loan capital exists, is merely that of actual money, of gold or silver, of that commodity whose substance serves as a measure of value, a large portion of this money-capital is necessarily purely fictitious, that is a title to some value just as the tokens of value. So far as money functions in the cycle of capital, it forms indeed for the moment a money-capital; it is rather exchanged for the elements of productive capital, or paid out as a medium of circulation in the realisation of revenue, and cannot, therefore, convert itself into loan capital for its owner. But so far as it is converted into loan capital, and the same money repeatedly represents loan capital, it is evident that it exists only at one point in the form of metallic money; at all other points it exists only in the form of title on capital. The accumulation of these titles, according to our analysis, arises from the actual accumulation, that is, from the transformation of the values of commodity-capital, etc., into money; but nevertheless the accumulation of these titles as such differs from the actual accumulation, from which it arises, and from the future accumulation, from which it arises, and from the future accumulation (the new process of production), which is promoted by the loaning of this money.

In the first instance loan capital exists always in the form of money,¹⁰¹ later as a title on money, since the money, in which it originally existed, is now held in the hand of the borrower as actual money. For the lender it has been transformed into title on money, a title of ownership. The same mass of actual money may, therefore, represent very different masses of money-capital. Mere money, whether it represent realised capital or realised revenue, becomes a loan capital through the simple act of loaning, by its conversion into a deposit, if we look upon the general form under a developed credit system. The deposit is a money-capital for the depositor. But in the hands of the banker it may be only a potential money-capital, which lies fallow in his strongbox instead of that of its owner.¹⁰²

With the growth of material wealth grows the class of money-capitalists; on one side the number and the wealth of retiring capitalists living on their incomes increases; on the other hand the development of the credit system is promoted, and with it the number of bankers, money lenders, financiers, etc.

With the development of the available money-capital grows also the mass of interest-bearing papers, government bonds, stocks, etc., as we have shown previously. At the same time grows also the demand for available

money-capital, since the jobbers, who speculate in these securities, play a prominent role on the money-market. If all the purchases and sales of these papers were only an expression of actual investments of capital, it would be correct to say, that they can have no influence on the demand for loan capital, since, when A sells his paper, he draws exactly as much money as B puts into the paper. But even if the paper itself exists, though not the capital (at least not as money-capital) originally represented by it, it always creates to that extent a demand for such money-capital. But at any rate it is then money-capital, which was previously at the disposal of B and is not at the command of A.

B.A. 1857. No. 4886. "Is it in your opinion a correct statement of the causes determining the rate of discount, when I say that it is regulated by the quantity of capital existing on the market, which is available for the discounting of commercial bills, as distinguished from other kinds of securities?" [Chapman]: "No, I hold that the rate of interest is affected by all convertible securities of current character; it would be wrong to limit the question simply to the discounting of bills; for when there is a strong demand for money on consols [deposited] or even treasury notes, as was strongly the case of late, and at a much higher than the commercial rate of interest, it would be absurd to say that our commercial world is not influenced by it; it is very essentially touched by it." — 4890. "When good and current securities, such as bankers accept, are on the market, and the owners take up money on them, it has surely an effect on the commercial world; for instance, I cannot expect that a man should give me his money at 5% on a commercial bill, when he can lend this money out at the same time at 6% on consols, etc.; it affects us in the same way; nobody can expect of me that I should discount his bills at 5½%, when I can lend my money out at 6%." — 4892. "Of people, who buy securities as fixed investments of capital for 2,000, or 5,000, or 10,000 pounds sterling, we do not speak as though they had any essential influence upon the money-market. When you ask me for the rate of interest on [a deposit of] consols, I speak of people, who transact business to the amount of hundreds of thousands, of so-called jobbers, who underwrite large amounts of public loans, or buy them on the market, and who must hold these papers until they can get rid of them at a profit; these people must take up money for this purpose."

With the development of the credit system great concentrated money-markets are created, such as London, which are at the same time the main

seats of trade in such securities. The bankers place the money-capital of the public in masses at the disposal of this unsavory crowd of dealers, and thus this breed of gamblers multiplies. "Money is generally cheaper at the stock exchange than anywhere else," says the incumbent of the Governor's chair of the Bank of England in 1848 before the secret Committee of Lords, C. D. 1848, printed, 1857, No. 219.)

In the discussion of the interest-bearing capital we have already shown, that the average interest for a long period of years, other circumstances remaining the same, is determined by the average rate of profit; this does not mean profits of enterprise, which are themselves nothing but profit minus interest.

It has also been mentioned, and will be further analysed in another place, that the variations of commercial interest, that is, of interest calculated by the money lenders for discounts and loans within the commercial world, meet in the course of the industrial cycle a phase, in which the rate of interest exceeds its minimum and reaches its average level, which it exceeds later, and that this movement is a result of a rise in profits.

However, two things must be noted here.

First: When the rate of interest stays up for a long time (we are speaking here of the rate of interest of a certain country, for instance England, where the average rate of interest is a fact for a certain long time, and presents itself also in the interest paid on loans for a long period, called private interest), it is an evident proof of the fact, that the rate of profit is high during this period, but it does not prove necessarily, that the rate of profits of enterprise is high. This last distinction is more or less removed for capitalists, who operate mainly with their own capital; they realise the high rate of profit, since they pay their own interest. The possibility of a high rate of interest of long duration is present when the rate of profit is high; this does not refer, however, to the phase of the actual stringency. But it is possible, that this high rate of profit may leave but a low rate of profit of enterprise, after the high rate of interest has been deducted. The rate of profit of enterprise may shrink, while the high rate of profit continues. This is possible, because the enterprises must be continued after they have once been started. During this phase operations are carried on to a large extent with a pure credit capital (capital of other people); and the high rate of profit may be speculative, prospective, in some places. A high rate of interest may be paid with a high rate of profit, while profit of enterprise is

declining. It may be paid (and this is done in part during times of speculation), not out of the profit, but out of the borrowed capital of another, and this may continue for a long time.

Secondly: The expression, that the demand for money-capital, and with it the rate of interest, grows, while the rate of profit is high, is not the same as that which is to the effect that the demand for industrial capital grows and with it the rate of interest is high.

In times of crisis the demand for loan capital, and with it the rate of interest, reach their maximum; the rate of profit, and with it the demand for industrial capital, are almost gone. In such times every one borrows only for the purpose of paying, in order to settle previously contracted obligations. On the other hand, in times of renewed activity after a crisis, loan capital is demanded for the purpose of buying, and for the purpose of transforming money-capital into productive and commodity-capital. And then it is in demand either by the industrial capitalist or the merchant. The industrial capitalist invests it in means of production and in labor-power.

The rising demand for labor-power can never be by itself a cause for a rising rate of interest, so far as this is determined by the rate of profit. A higher wage is never a cause of higher profits, although it may be one of the consequences of higher profits, in some particular phases of the industrial cycle.

The demand for labor-power may increase, because the exploitation of labor takes place under especially favorable circumstances, but the rising demand for labor-power, and thus for variable capital, does not in itself increase the profit; it rather lowers it to that extent. But the demand for variable capital may nevertheless increase with the demand for labor-power, and to that extent the demand for money-capital, and this may raise the rate of interest. The market price of labor-power then rises above its average, more than the average number of laborers are employed, and the rate of interest rises at the same time, because the demand for money-capital rises under such circumstances. The rising demand for labor-power makes this commodity dearer like any other, increases its price, but not the profit, which rests mainly upon the relative cheapness of just this commodity. But it raises under the given assumptions also the rate of interest, because it increases the demand for money-capital. If the money-capitalist, instead of loaning the money, should transform himself into an industrial capitalist, then the fact that he has to pay more for labor-power would not increase his

profit, but would rather decrease it in proportion. The constellation of conditions may be such, that his profit may rise nevertheless, but it will be in spite of the fact that he pays more for labor-power, and not because of it. This last circumstance, so far as it increases the demand for money-capital, is on the other hand sufficient to raise the rate of interest. If wages should rise for some reasons while the constellation is unfavorable, then the rise in wages would lower the rate of profit, but raise the rate of interest in proportion as it would increase the demand for money-capital.

Leaving the question of labor aside, the thing called “demand for capital” by Overstone consists only in a demand for commodities. The demand for commodities raises their price, either because it may rise above the average, or because the supply of commodities may fall below the average. If the industrial capitalist or the merchant must now pay 150 pounds sterling for the same mass of commodities for which he used to pay 100 pounds sterling, he would have to borrow 150 pounds sterling whereas he had to borrow but 100 pounds sterling formerly, and if the rate of interest were 5%, he would now have to pay 7½ pounds sterling of interest as against 5 pounds sterling of former times. The mass of the interest to be paid by him would rise because he now has to borrow more capital.

The whole attempt of Mr. Overstone consists in pretending that the interests of loan capital and of industrial capital are identical whereas his Bank Acts are precisely calculated to exploit the difference of these interests for the benefit of money-capital.

It is possible, that the demand for commodities, in case their supply has fallen below average, does not absorb any more money-capital than formerly. The same sum, or perhaps a smaller one, has to be paid for their total value, but a smaller quantity of use-values is received for the same sum. In this case the demand for loanable money-capital will remain the same, and the rate of interest will not rise, although the demand for commodities would have risen as compared to their supply, and consequently the price of commodities would have become higher. The rate of interest cannot be touched, unless the total demand for loan capital increases, and this is not the case under the above assumption.

The supply of an article may also fall below average, as it does in case of crop failures of corn, cotton, etc., and the demand for loan capital may increase, because the speculation in these commodities calculates on a rise in their prices and the first means of making them rise is to curtail for a

while a portion of their supply on the market. But in order to pay for the bought commodities without selling them, money is secured by means of the commercial bill system. In this case the demand for loan capital increases, and the rate of interest may rise in consequence of this attempt to prevent by artificial means the supply of this commodity to the market. The higher rate of interest expresses in that case an artificial reduction of the supply of commodity-capital.

On the other hand the demand for an article may rise, because its supply has increased and the article stands below its average price.

In this case the demand for loan-capital may remain the same or may even fall, because more commodities can be had for the same sum of money. A speculative formation of a supply might also occur, either for the purpose of taking advantage of a favorable moment for the ends of production, or in expectation of a future rise in prices. In this case the demand for loan capital might grow, and the rise in the rate of interest would then be an expression of an investment of capital in the formation of an extra supply of elements of productive capital. We consider here merely that demand for loan capital, which is influenced by the demand and supply of commodity-capital. We have explained on a previous occasion, that the changing condition of the process of reproduction in the phases of the industrial cycle has its effect upon the supply of loan capital. The trivial statement to the effect that the market rate of interest is determined by the supply and demand of (loan) capital, is shrewdly mixed up by Overstone with his own assumption, according to which loan capital is identical with capital in general, and in this way he tries to transform the usurer into the only capitalist and his capital into the only capital.

In times of stringency the demand after loan capital is a demand for means of payment and nothing else; it is by no means a demand for money as a means of payment. The rate of interest may rise very high at the same time, regardless of whether real capital, that is, productive and commodity-capital, exists in abundance or is scarce. The demand for means of payment is a mere demand for convertibility into money, to the extent that the merchants and producers can offer good security; it is a demand for money-capital in so far as it is not this other, in other words, so far as an advance of means of payment gives them not merely the form of money, but also the equivalent which they lack for making payment in whatever form. This is the point, where both sides of the current theory are right and wrong in their

opinion about crisis. Those who say that there is merely a lack of means of payment, have either the owners of bona fide securities alone in view, or they are fools who believe that it is the duty and power of banks to transform all bankrupt swindlers into solvent and solid capitalists by means of pieces of paper. Those who say that there is merely a lack of capital, are either harping on words, since in such times there is a mass of inconvertible capital in consequence of over-imports and overproduction, or they are referring only to such knights of credit as are now placed in conditions, where they cannot any longer get other people's capital for their operations, and who now demand that the bank should not only help them to pay for the lost capital, but also enable them to continue their swindling.

It is a basic principle of capitalist production, that the money, as an independent form of value, must stand opposed to commodities, or that exchange-value must assume an independent form in money, and this is possible only by making of one definite commodity the material, whose value measures all other commodities, so that it thus becomes the general commodity, the commodity par excellence as distinguished from all other commodities. This must become evident in two respects, particularly among capitalistically developed nations, who substitute other things for large masses of money, partly through credit operations, partly through credit money. In times of stringency, when credit shrinks or ceases entirely, money suddenly becomes the only means of payment and the only true existence of absolute value as opposed to all other commodities. Hence a universal depreciation of commodities, difficulty or even impossibility of transforming them into money, that is, into their own purely phantastic form. In the second place, credit money itself is but money in so far as it absolutely takes the place of actual money to the amount of its nominal value. With the export of gold its own convertibility becomes problematical, that is, its identity with actual money. Hence forcible measures, raising of the rate of interest, etc., for the purpose of safeguarding the conditions of this convertibility. This may be carried more or less to excess by mistaken legislation, resting upon false theories of money and enforced upon the nation by the interests of the money dealers, of Overstone and his like. The basis, however, is given with the basis of the mode of production itself. A depreciation of credit money (not to mention its imaginary depreciation) would unsettle all existing relations. The value of commodities is therefore sacrificed, for the purpose of safeguarding the

phantastic and independent existence of this value in money. As money-value it is secured only so long as money itself is secure. For the sake of a few millions of money many millions of commodities must therefore be sacrificed. This is inevitable under capitalist production and constitutes one of its beauties. In former modes of production this does not occur, because on the narrow basis, upon which they move, neither credit nor credit money can develop to any extent. So long as the social character of labor appears as the money-existence of commodities, and thus as a thing outside of actual production, money crises are inevitable, either independently of crises or intensifying them. On the other hand it is obvious that, so long as the credit of a bank is not shaken, it will alleviate the panic in such cases by increasing the credit money, and intensify it by contracting this money. All history of modern industry shows that metal would indeed be required only for the balancing of international commerce, whenever its equilibrium is disturbed momentarily, if only national production were properly organised. That the inland market does not need any metal even now is shown by the suspension of cash payments of the so-called national banks, that resort to this expedient whenever extreme cases require it as the sole relief.

In the case of two individuals it would be ridiculous to say that both of them have a balance of payment against one another in their mutual transactions. If they are mutually creditors and debtors of one another, it is evident that to the extent that their claims do not balance, one must be the creditor and the other the debtor for the remainder. But in the case of nations this is by no means so. And that it is not so is acknowledged by all economists through the statement, that the balance of payment may be for or against a nation, even if its balance of trade must ultimately be settled. The balance of payment differs from the balance of trade in so far as payment is a balance of trade which must be settled at a definite period. What crises accomplish is the crowding of the difference between the balance of payment and the balance of trade into a short time; and the definite conditions, which develop in the nation suffering from a crisis and facing the term when payment becomes due, carry with them such a contraction of the time of settlement. These conditions are, first the shipping away of precious metals; then the throwing away of consigned commodities; the exportation of commodities for the purpose of getting rid of them or of securing loans on them in the home market; the rising of the rate of interest, the calling in of credits, the falling of securities, the selling

out of foreign securities, the attraction of foreign capital for investment in these depreciated securities, and finally bankruptcy, which settles a mass of obligations. While this is going on, metal is often sent for some time into the country, where a crisis has broken out, because bills of exchange on it are unsafe and payment is best made in metal. This is further explained by the fact that in the case of a country like Asia all capitalist nations are generally direct or indirect debtors of it at the same time. As soon as these different circumstances exert their full effect upon the other involved nation, it likewise begins its export of gold and silver on account of the expiration of the date of payment, and the same phenomena are repeated.

In commercial credit the interest, being the credit price as distinguished from the cash price, enters only in so far into the price of commodities as the bills of exchange have a longer running time than the ordinary. Otherwise it does not. And this is explained by the fact that every one takes credit with one hand and gives it with the other. [This does not agree with my experience. F. E.] But so far as discount in this form enters into consideration here, it is not regulated by this commercial credit, but by the money-market.

If the demand and supply of money-capital, which determine the rate of interest, were identical with the demand and supply of actual capital, as Overstone maintains, then the interest would be simultaneously high or low according to different commodities, or different phases of the same commodity (raw material, partly finished product, finished product). In 1844 the rate of interest of the Bank of England fluctuated between 4% from January to September to 2½ and 3% from November to the end of the year. In 1845 it was 2½, 2¾, 3% from January to October, and between 3 and 5% during the remaining months. The average price of fair Orleans cotton was 6¼ d. in 1844 and 4 7/8 d. in 1845. On March 3, 1844, the cotton supply in Liverpool was 627,042 bales, and on March 3, 1845, it was 773,800 bales. To judge by the low price of cotton, the rate of interest should have been low in 1845, and it was indeed for the greater part of this time. But to judge by the yarn the rate of interest should have been high, for the prices were relatively and the profit absolutely high. From cotton at 4 d. per pound a yarn could be spun in 1845 with a spinning cost of 4 d. (No. 40 good second mule twist), or a total cost of 8 d. to the spinner, which he could sell in September and October 1845 at 10½ or 11½ d. per pound. (See the testimony of Wylie farther on.)

This whole question may be decided by the following considerations:

A supply and demand of loan capital would be identical with a demand and supply of capital in general (although this last phrase is absurd; for the industrial or commercial capitalist a commodity is a form of his capital, yet he never asks for capital as such, but only for this particular commodity as such, buys and sells it as a commodity, corn or cotton, regardless of the role which it has to play in the rotation of his capital), if there were no money lenders, and if in their stead the lending capitalists were in possession of machinery, raw materials, etc., which they would rent or loan just as houses are now, to the industrial capitalists, who are themselves part owners of these things. Under such circumstances the supply of loan capital would be identical with the supply of elements of production for the industrial capitalist, and of commodities for the merchant. But it is evident, that then the division of profit between the lender and borrower would depend primarily upon the proportion, in which this capital is loaned and in which it is the property of the one who employs it.

According to Mr. Weguelin (B. A. 1857) the rate of interest is determined by “the mass of unemployed capital” (252); it is “but an index of the mass of unemployed capital seeking investment” (271); later this unemployed capital becomes a “floating capital” (485) and by this he means “notes of the Bank of England and other means of circulation in the country, for instance the notes of provincial banks and the coins existing in the country....I include in the floating capital also the reserves of the banks” (502,503), and later he includes also gold bullion (503). Thus the same Mr. Weguelin says that the Bank of England has a great influence upon the rate of interest in times, when “we” (the Bank of England) actually have the greater portion of the unemployed capital in our hands (1198), while according to the above testimony of Mr. Overstone the Bank of England “is no place for capital.” Mr. Weguelin further says: “In my opinion the rate of discount is regulated by the quantity of the unemployed capital in the country. The quantity of unemployed capital is represented by the reserve of the Bank of England, which is in fact a metal reserve. Hence when the metal hoard is reduced, it reduces the quantity of unemployed capital in the country and consequently raises the value of the remaining quantity.” (1258.) J. Stuart Mill says, 1102: “The Bank is compelled, in order to keep its banking department solvent, to do its utmost to fill the reserve of this department, hence as soon as it finds that a drain begins, it must secure its

reserve and either reduce its discounts or sell securities.” — The reserve, so far as only the banking department is concerned, is a reserve for the deposits only. According to the Overstones the banking department is supposed to act only as a banker, without regard to any “automatic” issue of notes. But in times of actual stringency this institution, independently of the reserve of the banking department, which consists only of notes, keeps a sharp eye on the metal reserve, and must do so, if it would not fail. For in proportion as the metal reserve dwindles, disappears also the reserve of bank notes, and no one should know this better than Mr. Overstone, who has so wisely arranged this by his Bank Acts of 1844.

CHAPTER XXXIII. THE CURRENCY UNDER THE CREDIT SYSTEM.

“THE great regulator of the velocity of circulation is credit. This explains, why a sharp stringency in the money-market generally coincides with a full circulation.” (The Currency Question Reviewed, .) This is to be taken in a double sense. On one hand all methods, which save currency, are based upon credit. On the other hand, take, for instance, a 500 pound note. A gives it today to B in payment for a bill of exchange; B deposits it on the same day in his bank; his banker discounts with it on the same day a bill of exchange for C; C pays it to his bank, the bank gives it to the bill broker as a loan, etc. The velocity with which this note circulates here in purchases and sales is promoted by the velocity with which it always returns to some one in the form of a deposit and passes over to some one else in the form of a loan. The mere economising of the currency appears most highly developed in the Clearing House, the mere exchange of due bills of exchange, and the function of money preferentially as a means of payment for balancing mere remainders. But the existence of these bills rests itself upon credit, which the industrials and merchants mutually give to each other: If this credit declines, so does the number of bills, particularly of long time ones, and consequently also the effectiveness of this method of balancing accounts. And this economy, which consists in the elimination of money from the transactions, and which rests entirely upon the function of money as a means of payment, which in its turn rests again upon credit, can be only of two kinds (aside from the more or less developed technique in the concentration of these payments): Mutual claims of indebtedness, represented by bills of exchange or checks, are balanced either by the same banker, who merely transcribes the claim from the account of one to that of another, or by different bankers squaring accounts against each other.¹⁰³

The concentration of 8 to 10 million bills of exchange in the hands of one bill broker, such as the firm of Overend, Gurney & Co., was one of the principal means of expanding the scale of these balances locally. By this economy the effectiveness of the currency is increased, so far as a smaller quantity of it is required for the mere balancing of accounts. On the other hand the velocity of the money circulating as currency (by which it is

likewise economised) depends entirely upon the flow of purchases and sales, or also on the concatenation of payments, so far as they are made successively in money. But credit promotes and increases the velocity of currency. A single piece of money, for instance, may perform only five rotations, and remains for a certain time in each hand, as a mere medium of circulation, without the intervention of credit, when A, its original owner, buys from B, then B from C, then C from D, then D from E, then E from F, that is, when its transition from one hand to another is due only to actual sales and purchases. But when B deposits the money received from A in his bank and his banker issues it in the discounting of bills to C, and he buys from D, and D deposits it in his bank, and his banker lends it to E, who buys from F, then even its velocity as a mere medium of circulation (means of purchase) is promoted by several credit operations: the depositing of this money by B in his bank, the discounting of his banker for C, the depositing of D in his bank, and the discounting of this banker for E; four credit operations. Without these credit operations the same piece of money would not have performed five purchases successively in a given time. The fact that it changed hands without the promotion of actual sales and purchases, by deposits and discounts, has here accelerated its change of hands in the series of actual transactions.

We have seen previously, that one and the same bank note may be a deposit in different banks. It may also form different deposits in the same bank. The banker discounts with the note, which A has deposited, the bill of B, and B pays it over to C, who deposits the same note in the same bank that issued it.

We have already demonstrated in the discussion of the simple circulation of commodities (Volume I, Chapter III, 2), that the mass of the actually circulating money, assuming the velocity of currency and the economy of payments to be given, is determined by the prices of commodities and the mass of transactions. The same law rules the circulation of notes.

In the following table, the annual averages of the notes of the Bank of England are set down, so far as they were in the hands of the public, namely the amounts of 5 and 10 pound notes, those of 20 to 100 pound notes, and those of the larger notes between 200 and 1000 pounds sterling; together with the percentages of the total circulation supplied by each one of these classes. The amounts stand for thousands, the last three figures being left out.

(B. A. 1858, p. I, II.) The total mass of circulating bank notes has, therefore, positively decreased from 1844 to 1857, although the commercial business had more than doubled, as indicated by exports and imports. The smaller bank notes of 5 and 10 pounds sterling increased, as the table shows, from 9,263,000 in 1844 to 10,659,000 pounds sterling in 1857. And this took place simultaneously with the very heavy increase in the gold circulation of that time. On the other hand, there was a decrease of the notes of higher denominations (200 to 1000 pounds sterling) from 5,856,000 in 1852 to 3,241,000 pounds sterling in 1857, a decrease of more than 2½ millions. This is explained as follows: “On June 8, 1854, the private bankers of London permitted the stock banks to take part in the erection of the Clearing House, and soon after that the final clearing was established in the Bank of England. The daily balances were settled by transcribing them on the accounts, which the different banks keep in the Bank of England. By the introduction of this system the notes of high denomination, which the banks formerly used for balancing their mutual accounts, have become superfluous.” (B. A. 1858, p. V.)

To what a small minimum the use of money in wholesale trade has been reduced, may be seen in the table published in Volume I, Chapter III, page 157, footnote 1, which was furnished to the Committee on Bank Acts by

Morrison Dillon & Co., one of the largest of those London firms, from whom a small dealer can buy his entire stock of commodities of all kinds.

According to the testimony of W. Newmarch before the B. A. 1857, No. 1741, still other circumstances contributed to the economy in currency: The penny postage, the railroads, the telegraphs, in short, the improved means of communication; so that England can now carry on a five to six times larger business with about the same circulation of bank notes. It is also declared to be due to a marked degree to the withdrawal of the notes of a higher denomination than 10 pounds sterling from the circulation. This appears to him as a natural explanation for the fact that in Scotland and Ireland, where also one pound notes circulate, the circulation of notes has risen by about 31% (1747). The total circulation of bank notes in the United Kingdom, including the one pound notes, is said to be 39 millions (1749). The gold circulation 70 millions (1750). In Scotland the circulation of notes was 3,120,000 pounds sterling in 1834; 3,020,000 pounds sterling in 1844; and 4,050,000 pounds sterling in 1854 (1752).

From these facts alone it is evident, that it lies by no means with the banks issuing notes to increase the number of circulating notes, so long as these notes are at all times exchangeable for money. [Inconvertible bank notes are not taken into consideration at all here; inconvertible bank notes can become universal means of circulation only under conditions, in which they are actually backed up by national credit, as is the case of Russia at present. In that case they fall under the laws of the inconvertible national paper money, which have been developed already in Volume I, Chapter III, 2, c, Coin and Symbols of Value. — F. E.]

The quantity of circulating notes is regulated by the requirements of commerce, and every superfluous note wanders back immediately to the issuing party. Since in England only the notes of the Bank of England circulate universally as the legal means of payment, we may neglect at this point the slight and merely local circulation of the provincial banks.

In B. A. 1858 Mr. Neave, Governor of the Bank of England testifies: No. 947. Question: “Whatever measures you may take, the amount of notes, you say, remains the same, that is, about 20 million pounds sterling?” — Answer: “In ordinary times the wants of the public seem to require about 20 million pounds sterling.” — At certain periodically recurring times each year this is increased by one or one and half millions. If the public needs more, they can always, as I said, get them from the Bank of England.” —

948. “You said that during the panic the public did not want to allow you to reduce the amount of the notes; will you state your reasons?”— “In times of panic the public, it seems to me, has full power to secure notes; and of course, so long as the Bank has any obligation, the public can take notes from the Bank on this obligation.” — 949. “It seems, then, that at all times about 20 million notes of the Bank of England are required?”— “20 million notes in the hands of the public; it changes. It is 18½, 19, 20 millions, etc.; but on an average you may say 19-20 millions.”

Testimony of Thomas Tooke before the Committee of Lords on Commercial Distress (C. D. 1848-57) No. 3094: “The Bank has no power to expand the amount of its notes in the hands of the public at its own arbitrary will; it has the power to reduce the amount of notes in the hands of the public, but only by means of a very forcible operation.”

J. C. Wright, for 30 years a banker in Nottingham, having explained at length the impossibility, that a provincial bank should be able to set more notes into circulation than the public needs, says of the notes of the Bank of England: (C. D. 1848-57) No. 2844: “I know of no limit” (for the issue of notes) “for the Bank of England, but every surplus of the circulation will pass over into the deposits and thus assume another form.”

The same holds good for Scotland, where almost nothing but paper circulates, because there as well as in Ireland one pound notes are also in vogue and “the Scotch hate gold.” Kennedy, Director of a Scotch bank, declares that banks cannot even contract their circulation of notes, and is “of opinion that, so long as inland transactions require notes or gold in order to be carried on, the bankers must furnish as much currency as these transactions need — either on demand of their depositors or otherwise....The Scotch banks can contract their business, but they cannot exert any control over their issue of notes.” (Ibidem, No. 3446-48.) In like manner Anderson, Director of the Union Bank of Scotland, answers question No. 3678, asked ibidem: “Does the system of mutually exchanging notes” [among the Scotch banks] “prevent an overissue of notes on the part of the individual bank?”— “Yes; but we have a more effective means than the exchange of notes” [which has really nothing to do with this, but does indeed guarantee the ability of the notes of each bank to circulate throughout all of Scotland], “and that is the general custom in Scotland of keeping a bank account; every one who has any money at all has also an account in some bank and turns in daily all the money which he does not

need immediately for himself, so that at the end of every business day all the money is in the banks, except what each carries in his pockets.”

The same applies to Ireland, as shown by the testimony of the Governor of the Bank of Ireland, MacDonnell, and the Director of the Provincial Bank of England, Murray, before the same Committee.

The circulation of notes is just as independent of the state of the gold reserve in the cellars of the bank, which guarantees the convertibility of these notes, as it is of the will of the Bank of England. “On September 18, 1846, the circulation of the notes of the Bank of England was 20,900,000 pounds sterling and its metal reserve was 16,273,000 pounds sterling; on April 5, 1847, the circulation was 20,815,000 pounds sterling and the metal reserve was 10,246,000 pounds sterling. Hence no contraction of the currency took place in spite of the export of 6 million pounds sterling of precious metal.” (J. G. Kinnear, *The Crisis and the Currency*, London, 1847, .) Of course, this applies only to the conditions which prevail in England at present, and even there only so far as legislation does not decide differently concerning the relation between the issue of notes and the metal reserve.

Hence only the requirements of business itself exert an influence on the quantity of circulating money — notes and gold. In the first instance the periodical fluctuations, which repeat themselves every year, should be noted here, regardless of the general condition of business, so that for 20 years “in a certain month the circulation is high, in another low, and in a third definite month a middle point occurs.” (Newmarch, B. A. 1857, No. 1650.)

For instance, in August of every year a few millions, generally in gold, pass from the Bank of England into inland circulation, in order to pay the expenses of the harvest; since the principal payments to be made here are wages, bank notes are less serviceable in England for this purpose. By the close of the year this money has returned to the Bank. In Scotland there are almost nothing but one pound notes instead of Sovereigns; in this case, then, it is the circulation of notes which is expanded during the aforesaid term, and at another, that is, twice a year, in May and November, by about 3 or 4 millions; within fourteen days the reflux begins, and it is almost completed in one month. (Anderson, l. c., No., 3595-3600.)

The circulation of the notes of the Bank of England also experiences every quarter a momentary fluctuation on account of the quarterly payment of the “dividends,” that is, the interest on the national debt by which bank

notes are first withdrawn from circulation and then once more distributed between the public. But they return very soon. Weguelin (B. A. 1857, No. 38) states that this fluctuation of the circulation of notes amounts to two and half millions. Mr. Chapman of the notorious firm of Overend, Gurney & Co., however, calculates the disturbance created by this fluctuation in the money market at a far higher figure. "If you take 6 or 7 millions for taxes out of the circulation, for the purpose of paying dividends with them, there must be somebody, who places this amount within reach in the meantime." (B. A. 1857, No. 5196.)

Far more considerable and lasting are the fluctuations in the amount of the currency corresponding to the various phases of the industrial cycle. Let us listen to another member of that firm, the worthy Quaker Samuel Gurney (C. D. 1848-57, No. 2645): "At the end of October (1847) there were 20,800,000 pounds sterling in notes in the hands of the public. At that time a great difficulty prevailed in the matter of securing bank notes in the money market. This arose from the general apprehension that it would not be possible to secure them on account of the limitation of the Bank Acts of 1844. At present [March, 1848] the amount of bank notes in the hands of the public is...17,700,000 pounds sterling, but as there is no commercial alarm now, this is much more than is needed. There is no banker or no money dealer in London, who has not more bank notes than he can use." — 2650. "The amount of bank notes...out side of the keeping of the Bank of England forms a totally inadequate exponent of the actual state of the circulation, unless one considers at the same time...the condition of the commercial world and of credit." — 2651. "The feeling that we have a surplus at the present amount of currency in the hands of the public arises to a large degree from our present condition of great stagnation. With high prices and a brisk business 17,700,000 pounds sterling would give us a feeling of shortness."

[So long as the condition of business is such, that the returns on the loans given come in regularly and credit remains unshaken, the expansion and contraction of the currency depends simply upon the requirements of the industrials and merchants. Since gold does not enter into consideration in the wholesale trade, at least in England, and the circulation of gold aside from the fluctuations with the seasons, may be regarded as a rather constant magnitude for a long time, the circulation of the notes of the Bank of

England forms a sufficiently accurate measure of these changes. In a dull period after a crisis the circulation is smallest, with the reanimation of the demand comes also a greater demand for currency, which increases with the rising prosperity; the quantity of currency reaches its culminating point in the period of overtension and overspeculation — suddenly the crisis breaks out and over night the bank notes, yesterday still so plentiful, have disappeared from the market and with them the discounters of bills, the lenders of money on securities, the buyers of commodities. The Bank of England is called on for help — but even its powers are soon exhausted, the Bank Act of 1844 compels it to contract its circulation of notes at the very moment when all the world cries out for notes, when the owners of commodities cannot sell and yet are supposed to pay and are ready to make any sacrifice, if they can only secure bank notes. “During the alarm,” says the abovementioned banker Wright, l. c. No. 2930, “the country needs twice as much currency as in ordinary times, because the medium of circulation is stored up by bankers and others.”

As soon as the crisis breaks out, it is henceforth only a question of means of payment. But since every one is dependent upon the other for the coming in of these means of payment, and no one knows whether the other will be able to meet his payments when due, a stampede takes place for the means of payment available on the market, that is, the bank notes. Every one accumulates as many of them as he can secure, and thus the notes disappear from the circulation on the very day when they are needed most. Samuel Gurney (C. D. 1848-57, No. 1116) states that the amount of bank notes brought under lock and key in a moment of such terror in October 1847 to have been 4 to 5 million pounds sterling. — F. E.]

In this connection, a special interest attaches to the cross-examination of the associate of Gurney, the aforementioned Chapman, before the B. A. of 1857. I reproduce its principal contents summarily, although it touches also upon certain other points, which we shall have to analyse later.

Mr. Chapman has the following to say:

4963. “I do not hesitate to say, that I do not consider it right, that the money market should be in the power of any one individual capitalist (such as exist in London), who can create an enormous scarcity of money and a stringency, when the circulation just happens to be low....That is possible...there is more than one capitalist, who can take notes to the

amount of one or two million pounds sterling out of the currency, when it suits his purpose.” — 4995. A great speculator can sell one or two million pounds worth of consols and thus take the money out of the market. Something similar to this has happened quite recently, “it creates a very violent crisis.” —

4967. The notes are then indeed unproductive. “But that is nothing, when it serves a great purpose; its great purpose is to throw down the prices of funds, to create a money stringency, and to do that is quite within his power.” — An illustration: One morning there was a great demand for money in the Money Exchange; nobody knew its cause; somebody asked Chapman to lend him 50,000 pounds sterling at 7%. Chapman was astonished, his rate of interest was much lower; he accepted. Soon after that the man returned, took up another 50,000 pounds sterling at 7½%, then, 100,000 at 8%, and wanted still more at 8½%. Then even Chapman became frightened. Later it was found out that suddenly a considerable sum of money had been withdrawn from the market. But, says Chapman, “nevertheless I had loaned out a considerable amount of money at 8%; I was afraid to go farther; I did not know what was coming.”

It must not be forgotten, that, although 19 to 20 millions in notes are continually supposed to be in the hands of the public, nevertheless that portion of notes, which actually circulates, and on the other hand that portion, which is held unemployed by the banks as a reserve, continually differ considerably from one another. If this reserve is large, and therefore the actual circulation small, it means from the point of view of the money-market, that the circulation is full, money is plentiful; if the reserve is small, and the actual circulation full, then the language of the money-market says that the circulation is low, money is scarce, that is to say, the portion representing unemployed loan capital is small. A real expansion or contraction of the circulation in such a way, that it remains independent of the phases of the industrial cycle and leaves unchanged the amount needed by the public, occurs only for technical reasons, for instance, on the dates when taxes are due or the interest on a national debt. When taxes are paid, notes and gold beyond the ordinary amount flow into the Bank of England and practically contract the circulation without regard to its needs. The reverse takes place when the interest on the national debt is paid. In the first case, loans are demanded from the bank in order to secure currency. In the last case, the rate of interest falls in the private banks on account of the

momentary growth of their reserves. This has nothing to do with the absolute mass of currency, but only with the banking firm that sets this currency into circulation, and for whom this process represents itself as a loaning of loan capital, the profit of which it pockets.

In the one case there is a temporary displacement of the circulating medium, which the Bank of England balances by short loans at low interest shortly before the quarterly taxes or the quarterly dividends on the national debt become due; The issue of these supernumerary notes first fills up the gap caused by the payment of the taxes, while their return to the bank soon after brings back the excess of notes thrown into circulation by the payment of dividends to the public.

In the other case a low or full circulation means simply a different distribution of the same mass of currency into active circulation and deposits, which serve as an instrument of loans.

On the other hand, if the number of notes is increased by a flow of gold into the Bank of England, then these notes assist in the discounting of bills outside of the bank and return to it by the payment of loans, so that the absolute mass of the circulating notes is but momentarily increased.

If the circulation is full on account of the expansion of business (which may take place even though prices be relatively low), then the rate of interest may be relatively high on account of the demand for loan capital in consequence of rising profits and increased new investments. If it is low, on account of the contraction of business, or, perhaps, on account of a great fluidity of credit, then the rate of interest may be low even though prices be high. (See Hubbard.)

The absolute quantity of the circulation has a determining influence on the rate of interest only in times of stringency. The demand for a full circulation may either express merely a demand for means of hoarding (aside from the reduced velocity of the circulation of money and that of the conversion of the same identical pieces of money into loan capital) owing to lack of credit, as was the case in 1847, when the suspension of the Bank Acts did not cause any expansion of the circulation, but sufficed to draw forth the hoarded notes and to throw them into circulation. Or it may be that more means of circulation are actually required under prevailing circumstances, as was the case in 1857, when the circulation actually expanded for some time after the suspension of the Bank Acts.

Otherwise the absolute mass of the circulation has no influence upon the rate of interest, since the circulation, assuming the economy and velocity of the currency to be constant, is determined in the first place by the prices of commodities and the mass of the transactions (one of these elements generally paralysing the action of the other), and in the second place by the state of credit, whereas it does not by any means exert any reverse influence on the state of credit; and, finally, since the prices of commodities and interest have not necessarily any connection with each other.

During the Bank Restriction Act (1797-1820) there was a superfluity of currency, the rate of interest was always much higher than it became since cash payments were resumed. Later it fell rapidly with the restriction of the issue of notes and rising quotations of bills. In 1822, 1823, and 1832 the general circulation was low, and so was the rate of interest. In 1824, 1825, and 1836 the circulation was full and the rate of interest rose. In the summer of 1830 the circulation was full, the rate of interest low. Since the discoveries of gold the gold circulation of all Europe has expanded, the rate of interest risen. The rate of interest, then, does not depend upon the quantity of the circulating money.

The difference between the issue of currency and loans of capital is best shown in the real process of reproduction. We have seen, there (Volume II, Part III), in what manner the different component parts of the production are exchanged for one another. For instance, the variable capital consists substantially of the means of subsistence of the laborers, a portion of their own product. But this is paid over to them piecemeal in money. The capitalist has to advance this, and it depends very much on the organization of the credit system, whether he can pay out the new variable capital next week with the old money, which he paid out last week. The same holds good with regard to the acts of exchange between the different component parts of the total social capital, for instance, between the articles of consumption and the means of production of articles of consumption. The money for their circulation must, as we have seen, be advanced by one or both of the exchanging parties. It remains thereupon in the circulation, but returns after the consummation of the exchange always to him who advanced it, since it had been advanced by him in excess of his actually employed industrial capital (Volume II, Chapter XX.). Under a developed credit system, when the money is concentrated in the hands of the banks, it is they, at least nominally, who advance it. This advance refers only to the

money existing in circulation. It is an advance of currency, not of the capitals, which the credit system circulates.

Chapman 5062. "There may be times, when the bank notes in the hands of the public constitute a very large amount, and yet none may be had." Money exists also during a panic. But every one takes good care not to convert it into loanable capital; every one holds on to it for the purpose of meeting real payments.

5099. "The banks in the rural districts send their unemployed surplus to you and other London firms?"— "Yes." — 5100. "On the other hand, the factory districts of Lancashire and Yorkshire have bills of exchange discounted by you for business purposes?"— "Yes." — 5101. "So that in this way the superfluous money of a certain district is utilised for the requirements of another district?"— "Quite right."

Chapman says that the custom of the banks to invest their surplus money-capital for a short time in consols and treasury notes has decreased considerably of late, since the custom has been introduced to loan this money at call, reclaimable from day to day. For his own person he considers the purchase of such papers as very impracticable for his business. He prefers to invest his surplus money-capital in good bills of exchange, a part of which becomes due every day, so that he can always be sure of knowing how much ready money he can count on from day to day. [5001 to 5005.]

Even the growth of exports assumes more and more for every country, but particularly for the country granting the credit, the aspect of an increasing demand on the inland money-market, which is not felt, however, until the time of stringency. In times of increasing exports the manufacturers usually draw bills of exchange of long duration on the export merchant who receives consignments of British goods. (5126.) — 5127. "It is not frequently the case, that an agreement exists, to renew these bills from time to time?" — [Chapman:] "This is a matter which they keep secret; we should not admit any such bills....It may surely take place, but I cannot say anything about this." [The innocent Chapman.] 5123. "When a great increase takes place in the exports, such as that of last year which alone amounted to 20 million pounds sterling, does not that in itself lead to a large demand for capital in order to discount bills representing these exports?"— "Undoubtedly." — 5130. "Since England as a rule gives credit to foreign countries for all its exports, would not that imply the absorption of a corresponding additional capital for the time it lasts?"— "England

gives an enormous credit; but in return it takes credit for its raw materials. Drafts as are made out against us by America always for sixty days, and by other countries for ninety days. On the other hand we give credit; when sending goods to Germany, we give two or three months.”

Wilson asks Chapman (5131), whether bills on England are not drawn simultaneously with the loading of these raw materials and colonial goods destined for importation, and whether these bills do not arrive together with the bills of lading. Chapman thinks so, but does not know anything about these “commercial” transactions, and suggests that more expert men be asked. — In the export to America, says Chapman, the “commodities are symbolised in transit”; this gibberish signifies that the English export merchant draws against his goods on one of the great American banking firms in London by means of a bill of exchange running for four months, and this firm receives collateral from America.

5136. “Are not negotiations with far distant countries carried on by the merchant, who waits for his capital until the goods are sold?”— “There may be some firms of great private wealth, who are able to invest their own capital without taking advances on goods; but these goods are mainly transformed into advances by the endorsement of well known firms. — 5137. “These firms are established in...London, Liverpool, and elsewhere.” — 5138. “It makes no difference, then, whether the manufacturer has to give up his own money, or whether he gets some merchant in London or Liverpool to advance it; it always remains an advance made in England?”— “Quite right. The manufacturer has to do with this only in a few cases” [but in 1847 in almost every case]. “For instance, a dealer in manufactured goods, in Manchester, buys commodities and ships them through a responsible firm in London; as soon as the London firm has convinced itself, that everything has been packed as per agreement, he draws a bill running for six months on this London firm against these commodities bound for India, China, or some other country; then the banking world comes in and discounts this bill for him; so that about the time, when he has to pay for these commodities...” — 5139. “But even if this dealer now has the money, the banker had to advance it to him first?”— “The banker has the bill of exchange; the banker has bought the bill; he utilises his banking capital in this form, that is in the discounting of commercial bills.” [Hence even Chapman does not regard the discounting of bills as an advance of money, but as a purchase of commodities. — F. E.] — 5140. “But still this

constitutes always a part of the demands on the money-market in London?”— “Undoubtedly; this is the essential occupation of the money-market and of the Bank of England. The Bank of England is just as glad to get these bills as we, it knows that they are a good investment.” — 5141. “In this way, in proportion as the export business grows, the demand in the money-market grows likewise?”— “In proportion as the prosperity of the country grows, we” [the Chapmans] “partake in it.” — 5142. “If, then, the various fields of investment of capital expand suddenly, the natural consequence is a rise of the rate of interest?”— “There is no doubt of it.”

In 5143 Chapman cannot “quite understand, that with our large exports we had so much use for gold.”

In 5144 the venerable Wilson asks: “Cannot it be that we are giving more credit on our exports than we are taking on our imports?”— “For myself, I should doubt this point. If any one gets accepts on his Manchester goods shipped to India, you cannot accept for less than ten months. We had, and this is quite certain, to pay America for its cotton some time before India paid us; but what effect this has, to analyse that is a very fine point.” — 5145. “When we, as we did last year, had an increase in the exports of manufactured goods to the amount of 20 million pounds sterling, we must have had before that a very considerable increase in the imports of raw materials” [and even in this way overexports are identical with overimports, and overproduction with over-commerce] “in order to produce this increased quantity of goods?”— “Undoubtedly; we must have had a very considerable balance to pay; that is, the balance must have been against us at the time, but in the long run the quotations of bills of exchange with America are in our favor, and we have received for some time large shipments of precious metals from America.”

5148. Wilson asks the arch usurer Chapman, whether he does not regard his high interest as a sign of great prosperity and a high rate of profit. Chapman, evidently surprised at the naïveté of this sycophant, assents to this, of course, but is sincere enough to add the following clause: “There are some, who cannot help themselves in any other way; they have obligations to fulfill, and they must fulfill them, whether it be profitable or not; but if it lasts” [the high rate of interest] “it would indicate prosperity.” — Both of them forget that a high rate of interest may also indicate that, as it did in 1857, the roving knights of credit are infesting the country, and that these gentlemen can afford to pay a high interest, because they pay it out of other

people's pockets (whereby they take part in the fixing of the rate of interest for all others) and meanwhile live in grand style on anticipated profits. At the same time this may indeed result in a very profitable business for manufacturers and others. The returns become wholly deceptive by the loan system. This explains also the following statements, which require no explanation so far as the Bank of England is concerned, because it discounts at a lower rate than others when the rate of interest is high.

5156. "I may well say," says Chapman, "that the amounts of our discounts are at their maximum at the present, when we had a high rate of interest for such a long time." [Chapman said this on July 21, 1857, a few months before the crash.] — 5157. "In 1852" [when the rate of interest was low] "they were not so high by far." For the business was indeed a great deal sounder then.

5159. "If the market were overflowing with money...and the banking discount low, we should have a decrease of bills of exchange....In 1852 we were in an entirely different phase. The exports and imports of the country were then nothing as compared to the present." — 5161. "Under this high rate of discount our discounting business is as high as in 1854." [When the rate of interest was from 5 to 5½%.]

Very amusing is that part of the testimony of Chapman, in which he shows that his class regard the money of the public indeed as their property and pretend to have a right to having the bills discounted by them always converted. The ingenuousness of the questions and answers is great. It becomes the duty of legislation to make the bills accepted by large firms always convertible; to take pains that the Bank of England should under all circumstances continue to give discount to the bill brokers. And yet three of these bill brokers failed in 1857 for about 8 millions, while their own capital was infinitesimal compared to their debts. — 5177. "Do you mean to say by this that in your opinion they" [that is bills accepted by the Barings or Loyds] "should be convertible by compulsion, in the way that a note of the Bank of England is now convertible into gold by compulsion?" — "I am of the opinion, that it would be a very lamentable thing, if it were not discountable; a very extraordinary situation, that a man would have to suspend payment, because he holds accepts by Smith, Payne & Co., to Jones, Loyd & Co., and cannot discount them." — 5178. "Is not an accept of the Barings an obligation, to pay a certain amount of money when the bill becomes due?" — "That is quite right; but Messrs. Baring, if they undertake

such an obligation, like every merchant who accepts such an obligation, do not dream in the least that they shall have to pay in Sovereigns; they figure on paying in the Clearing House.” — 5180. “Do you mean, then, that a sort of machinery should be thought out, by means of which the public would be empowered to receive money before the bill becomes due, by having somebody else discount it?”— “No, not by the accepting party; but if you mean to say that we shall not have the possibility to have commercial bills discounted, then we must change the whole constitution of things.” — 5182. “You believe, then, that it” [a commercial bill] “should be convertible into money, exactly like a note of the Bank of England must be convertible into gold?”— “Very decidedly, under certain circumstances.” — 5184. “You believe, then, that the institutions of currency should be arranged in such a way that a commercial bill of undoubted solidity should at all times be convertible in money like a bank note?”— “That I believe.” — 5185. “You do not go so far as to say either the Bank of England or anybody else should be compelled by law to convert it?”— “I go indeed so far as to say that if we make a law for the regulation of the currency, we should take steps to prevent the possibility of inland commercial bills becoming inconvertible, to the extent that such bills are undoubtedly solid and legitimate.” — This is the convertibility of the commercial bill against the convertibility of bank notes.

5189. “The money dealers of the country represent in fact only the public.” — So did Mr. Chapman later before the jury in the Davison case. See the Great City Frauds.

5196. “During the quarterly terms” [when the dividends are paid] “it is...absolutely necessary, that we should turn to the Bank of England. If you take 6 or 7 millions out of the revenue of the state in anticipation of the dividends, somebody must be there, who will in the meantime advance this amount.” — [In this case it is a question of a supply of money, not of capital or loan capital.]

5169. “Every one familiar with our commercial world must know that if we are in such circumstances that treasury notes become unsalable, that obligations of the East Indian Company are completely useless, that the best commercial bills cannot be discounted, a great apprehension must reign among those whose business places them in a position where they must make payment immediately on simple demand in customary currency, and this is the case with all bankers. The effect of this is then that everybody

doubles his reserves. Now just look what the effect of this is in the whole country, when every country banker, of whom there are about 500, has to instruct his London correspondent to remit to him 5,000 pounds sterling in bank notes. Even if we take such a small amount as this for an average, which is quite absurd, we arrive at 2½ million pounds sterling, which are withdrawn from circulation. How are they to be replaced?"

On the other hand the private capitalists, etc., who have money do not care to let go of it at any interest, for they say, according to Chapman, 5194: "We prefer to have no interest at all rather than to be in doubt, whether we can get the money when we need it."

5173. "Our system is this: We have 300 million pounds sterling worth of obligations, the payment of which in coin of the realm may be demanded at any moment; and this coin of the realm, if we use all of it for this purpose, amounts to 23 million pounds sterling, or thereabout; is not that a condition, which may throw us into convulsions at any moment?" Hence we have in times of crisis the sudden change of the credit system into a monetary system.

Aside from the panic in the home market during crises, there can be any mention of the quantity of money only in so far as it concerns metal, which is the world money. And this is precisely what Chapman excludes; he speaks only of 23 millions in bank notes.

The same Chapman, 5218. "The original cause of the disturbance of the money-market" [in April and later in October] "was undoubtedly in the quantity of money required for the regulation of the quotations of bills of exchange, in consequence of the extraordinary imports of the year."

In the first place, this reserve of world market money had then been reduced to its minimum. In the second place it served at the same time as a security for the convertibility of the credit money, the bank notes. It combined in this way two quite different functions, which, however, proceed both of them from the nature of money, since real money is always world money, and the credit money always rests upon the world money.

In 1847, without the suspension of the Bank Acts of 1844, "the Clearing Houses could not have carried on their business." (5221.)

That Chapman nevertheless had a suspicion of the coming crisis, is shown by the following statement: 5236. "There are certain conditions of the money-market (and the present one is not far removed from that), in which money is very difficult, and one has to have recourse to a bank."

5239. “As for the amounts taken by us out of the bank on Friday, Saturday and Monday, October 19, 1847, we should have been only too grateful on the following Wednesday, if we could have gotten back the bills of exchange; the money returned to us immediately after the panic was over.” — On Tuesday, October 23, the Bank Acts were suspended, and this broke the crisis.

Chapman believes (5274) that the bills running simultaneously on London amounted to 100 or 120 million pounds sterling. This did not include the local bills on provincial places.

5287. “While in October, 1856, the amount of the notes in the hands of the public rose to 21,155,000 pounds sterling, there was nevertheless a very extraordinary difficulty in raising money; although the public had so much in its hands, we could not get our fingers on it.” — This was due to the fear, caused by the panic, in which the Eastern Bank found itself for a time (March 1856).

5190-92. As soon as the panic is over, “all bankers who make their profits out of interest begin at once to employ their money.”

5302. Chapman does not explain the unrest going with the decrease of the bank reserve out of the apprehension concerning the deposits, but attributes it to the fact that all those, who suddenly may be compelled to pay large sums of money, know very well that they may be driven to seek their last refuge in the bank, when a panic seizes the money-market; and “when the bank has a very small reserve, it is not glad to receive us; on the contrary.”

By the way it is nice to observe the way in which the reserve dwindles away as a really existing magnitude. The bankers keep a minimum for their current business either in their own hands or with the Bank of England. The bill brokers hold the “loose bank money of the country” without any reserve. And the Bank of England has nothing to offset its debt for deposits but the reserves of bankers and others, together with some public deposits, etc., which it permits to be drained to its very lowest level, for instance to 2 millions. Aside from these 2 millions of paper, then, this whole swindle has no other reserve but the metal reserve in times of crisis (and this reduces the reserve, because the notes, which come in to replace outgoing metal, must be annulled), and thus every reduction of this reserve by the expenditure of gold increases the crisis.

5306. "If no money were available to settle the balances in the Clearing House, I do not see that we could do anything else but to come together and make our payments in first drafts, checks on the Treasury Department, Smith, Payne & Co., etc." — 5307. "That is to say, if the government should fail to supply you with means of circulation, you would create one for yourself?" — "What are we going to do? The public comes in and takes the circulating medium out of our hands; it does not exist." — 5308. "Then you would simply do in London what is done in Manchester every day?" — "Yes."

Particularly good is the reply of Chapman to a question asked by Cayley, a Birmingham man of the Attwood school, with regard to Overstone's conception of capital. 5315. "It has been stated before this Committee, that it is not money, but capital, which is demanded in a panic like that of 1847; what is your opinion on this?" — "I do not understand you; we deal only in money; I don't understand what you mean." — 5316. "If you mean thereby" [namely by commercial capital] "the mass of money belonging to himself, which a man has in his business, if you call that capital, it forms generally a very small part of the money, with which he operates in his transactions by means of the credit given to him by the public" — that is, by the intervention of the Chapmans.

5339. "Is it from lack of wealth that we suspend our cash payments? — By no means...We have no lack of wealth, but we move under a most artificial system, and when we have an immense superincumbent demand for our medium of circulation, it may lead to conditions, which prevent us from securing this medium of circulation. Should the entire commercial industry of the country be laid lame on this account? Should we close all avenues of employment? — 5338. "Should the question be asked, what we want to maintain, whether the cash payments or the industry of the country, I know which of the two I should drop."

Concerning the hoarding of bank notes "with the intention of intensifying the panic, or drawing advantages from its results" he says that this may be done easily. Three large banks would be sufficient. 5383. "Should it not be known to you, a man familiar with the great firms of our metropolis, that capitalists utilise these crises to make enormous profits out of the ruin of those, who fall victims?" — "There can be no doubt of it." — And we may well believe Mr. Chapman on this score, although he finally broke his own neck in the attempt of making "enormous profits out of the

ruin of his victims.” For while his associate Gurney says “Every change in business is advantageous for him who is posted,” Chapman says: “The one portion of society knows nothing about the other; there is, for instance, the manufacturer, who exports to the continent, or who imports his raw material, he knows nothing of the other, who deals in gold bullion.” (5046.) — And thus it happened, that one fine day Gurney and Chapman themselves “were not posted” and went into an ill-famed bankruptcy.

We have seen previously, that the issuing of notes does not signify an advance of capital in all cases. The following testimony of Tooke before the C. D. Committee of Lords, 1848, proves merely that an advance of capital, even if accomplished by the bank by an issue of new notes, does not signify straightway an increase in the number of circulating notes.

3099. “Do you believe, that the Bank of England could extend its loans considerably, without bringing about an increased issue of notes?” — “There are abundant facts at hand to prove this. One of the most striking examples was in 1835, when the Bank made use of the West Indian deposits and of the loan from the East Indian Company to increase its loans to the public; at the same time the amount of notes in the hands of the public actually decreased somewhat....Something similar to this is noticeable in 1847 at the time of the paying of the railroad deposits in the Bank; the securities [in discount and deposits] rose to about 30 millions, while no appreciable effect took place on the amount of notes in the hands of the public.”

Aside from the bank notes the wholesale trade has another medium of circulation, which is far more valuable to it, namely the bills of exchange. Mr. Chapman showed us, how essential it is for a regular flow of business that good bills of exchange should be taken in payment everywhere and under all conditions. If bills of exchange are no longer good, what in the world is to be done? How do these two media of circulation stand towards one another?

Gilbart says on this score: “The restriction of the amount of the circulation of notes increases regularly the amount of the circulation of bills of exchange. The bills are of two kinds — commercial bills and banker’s bills — if money becomes scarce, then the money lenders say: “You draw on us and we will endorse,” and when a provincial banker discounts a bill for some customer, he does not give him cash money, but his own draft for 21 days on his London agent. These bills serve as a medium of circulation.” (G. W. Gilbart, *An Inquiry into the Causes of the Pressure, etc.*, .)

This is corroborated in a somewhat modified form by Newmarch, B. A. 1857, No. 1426: "There is no connection between the fluctuations in the amount of the circulating bills and those of the circulating bank notes...the only rather uniform result is...that as soon as a stringency in the money-market occurs, such as is indicated by a raising of the rate of discount, the volume of the circulation of bills is considerably increased and vice versa."

However, the bills of exchange written in such times are by no means only the short bank bills mentioned by Gilbart. On the contrary, they are largely bills of accommodation, which represent no real business at all, or at least only transactions made for the purpose of drawing bills of exchange on them; we have given sufficient illustrations of both. Hence the "Economist" (Wilson) says in comparing the security of such bills with that of bank notes: "Bank notes payable on presentation can never stay out in excess, because the excess would always return to the bank for exchange, while two-months drafts may be issued in great superabundance, as there is no means of controlling their issue until they become due, when they may have been replaced by others. That a nation should admit the security of the circulation of bills payable at some future date, but raise doubts against a circulation of paper money payable on presentation, is completely unintelligible to us." (Economist, 1847, .)

The quantity of the circulating bills is, therefore, like that of the bank notes, merely determined by the requirements of commerce; in ordinary times the circulation of bills running in the fifties together with about 39 millions in bank notes amounted to about 300 millions, and from 100 to 120 millions of this were made out on London alone.

The volume of the circulation of bills has no influence on the circulation of notes, and is influenced by the latter only in times of stringency of money, when the quantity of bills increases and their quality deteriorates. Finally, at the time of a crisis, the circulation of bills fails completely; no man can make use of a promise to pay, since every one wants to accept only cash payment; only the bank note retains, at least so far in England, its ability to circulate, because the nation with its total wealth backs up the Bank of England.

We have seen that even Mr. Chapman, though himself a magnate of the money-market in 1847, complained bitterly, that there were a few large money-capitalists in London strong enough to carry disorder into the whole money-market at any given moment and thereby to bleed the smaller money

dealers. There were several large sharks of this kind, he said, who could considerably intensify a stringency, by selling one or two millions worth of consols and thereby taking an equal amount of bank notes (and at the same time of available loan capital) out of the market. To transform a stringency into a panic by the same maneuver, the joint action of three large firms would be sufficient.

The greatest capital power in London is, of course, the Bank of England, which, however, is prevented by its position as a semi-government institution from making too brutal a use of its power. Nevertheless it also knows enough about ways and means of making money, particularly since the Bank Acts of 1844.

The Bank of England has a capital of 14,553,000 pounds sterling, and commands besides about 3 million pounds sterling of a "Remainder," that is, undistributed profits, and furthermore all moneys collected by the government for taxes, etc., which must be deposited there until they are needed. Add to this the amount of other deposits, about 30 million pounds sterling in ordinary times, and the bank notes issued without a reserve, and we shall find that Newmarch made a rather conservative estimate, when he said (B. A. 1857, No. 1889): "I have convinced myself, that the total amount of the funds employed continually in the [London] money-market may be estimated at about 120 million pounds sterling; and of these 120 millions the Bank of England commands a very considerable portion, about 15 to 20%."

So far as the Bank issues notes, which are not covered by the metal reserve in its vaults, it creates symbols of value, that form not only currency, but also additional, even if fictitious, capital for it to the nominal amount of these unprotected notes. And this additional capital yields an additional profit for it. — In B. A. 1857, Wilson asks Newmarch, No. 1563: "The circulation of a bank's own notes, that is, on an average the amount remaining in the hands of the public, forms an addition to the effective capital of that bank, does it not?" — "Assuredly." — 1564. "All profits, then, which the bank derives from this circulation, is a profit arising from credit, not from a capital actually owned by it?" — "Assuredly."

The same is true, of course, of the private banks issuing notes. In his answers Nos. 1866 to 1868 Newmarch considers two-thirds of all bank notes issued by them (the last third has to be covered by a metal reserve in

these banks) as “a creation of so much capital,” because hard cash is saved to this amount. The profit of the banker may not be larger than that of other capitalists, notwithstanding all this. The fact remains, however, that he draws the profit out of this national saving of hard cash. The fact that a national saving becomes a private profit does not shock the bourgeois economist in the least, since profit is under all circumstances the appropriation of national labor. Is there anything more insane than, for instance, the Bank of England in 1797 to 1817, whose notes have credit only by the backing of the state, taking payment from the state, and from the public, in the form of interest on government loans for the power, granted to it by the state, to transform these same notes from paper into money and then to loan them to the state?

The banks have still other means of creating capital. According to the same Newmarch the provincial banks, as mentioned above, have the habit of sending their superfluous funds (that is, notes of the Bank of England) to London bill brokers, who send them discounted bills of exchange in return. With these bills the bank serves its customers, since it follows the rule not to issue the bills of exchange received from its local customers any more, in order that the business transactions of these customers may not become known in their own neighborhood. These bills received from London do not only serve for the purpose of being issued to customers, who have to make payments direct to London, unless these customers should prefer to get the bank's own draft on London; they serve also for the settlement of payments in the province, for the endorsement of the bankers secures local credit for them. In Lancashire, for instance, all the local banks' own notes and a large portion of the notes of the Bank of England, have been crowded out of the circulation by such bills. (Ibidem, 1568 to 1574.)

We see here, then, how the banks create credit and capital, 1) by the issue of their own notes, 2) by writing out drafts on London running as long as 21 days but paid to them in cash immediately on being written, and 3) by paying out discounted bills of exchange, which are endowed with credit primarily and essentially by endorsement through the bank, at least for the local district.

The power of the Bank of England is shown in its regulation of the market rate of interest. In times of normal business it may happen, that the Bank cannot prevent a moderate drain of gold from its metal reserve by raising the rate of discount,¹⁰⁴ because the demand for means of payment

is satisfied by the private banks, stock banks and bill brokers, who have gained considerably in capital power during the last thirty years. In that case the Bank of England must use other means. But for critical moments, the statement made by Banker Glyn (of Glyn, Mills, Currie & Co.) before the C. D. 1848-57 still holds good: — 1709. “In times of great stringency in the country the Bank of England commands the rate of interest.”— “In times of extraordinary stringency...when the discounts of the private bankers or brokers are relatively restricted, they fall to the Bank of England, and then it has the power to fix the market rate of interest.”

It is true, that the Bank of England, being a public institution under government protection, cannot exploit its power ruthlessly, in the same way that private institutes may. For this reason Hubbard says before the Banking Committee B. A. 1857, No. 2844: “Is it not true, that when the rate of discount is highest, the Bank of England gives the cheapest service, and when lowest, then the brokers are the cheapest?”— “That will always be the case, for the Bank of England never comes down as low as its competitors, and when the rate is highest, it never goes quite so high.”

But nevertheless it is a serious event in business life, when the Bank of England draws the screw tighter in times of crisis, as the saying is, that is, when it raises the rate of interest, which is already above the average, still higher. “As soon as the Bank of England tightens the screw, all purchases for export into foreign countries cease...the exporters wait, till the depression of prices has reached its lowest point, and only then and not before do they buy. But when this point is reached, the quotations have once more become settled — gold ceases to be exported, before this lowest point of the depression is reached. Purchases of commodities for export may possibly bring back a part of the money sent abroad, but they come too late to prevent the drain.” (G. W. Gilbart, *An Inquiry into the Causes of the Pressure on the Money Market*, London, 1840, .)— “Another effect of the regulation of the currency by means of foreign quotations on bills of exchange is that it brings about an enormous rate of interest in times of crisis.” (L. c., .)— “The costs arising out of the restoration of the quotations on bills of exchange fall upon the productive industry of the country, whereas in the course of this process the profit of the Bank of England is positively increased by the fact that it continues its business with a smaller amount of precious metal.” (L. c., .)

But, says friend Samuel Gurney, “These great fluctuations of the rate of interest are advantageous for the bankers and money dealers — all fluctuations in business are advantageous for him who is posted.” And even though the Gurneys skim the cream off the ruthless exploitation of the precarious condition of business, whereas the Bank of England cannot do this with the same liberty, nevertheless it also makes quite nice profits — not to mention the private profits, which of their own account fall into the lap of the directors, who have an exceptional opportunity to understand the general condition of business. According to a statement made before the Lord’s Committee of 1817 on the matter of the resumption of specie payments these profits of the Bank of England for the entire period from 1797 to 1817 stood as follows:

Bonuses and increased dividends...	7,451,136	New stock divided among proprietors...	7,276,500	Increased value of capital...	14,553,000
Total...	29,280,636				

on a capital of 11,642,100 pounds sterling in 19 years. (D. Hardcastle, Banks and Bankers, 2nd edition, London, 1843, .) If we estimate the total profits of the Bank of Ireland, which also suspended specie payments in 1797, by the same principle, we obtain the following result:

Dividends as by returns due 1821...	4,736,085	Declared bonus...	1,225,000	Increased assets...	1,214,800	Increased value of capital...	4,185,000	Total...	11,360,885
-------------------------------------	-----------	-------------------	-----------	---------------------	-----------	-------------------------------	-----------	----------	------------

on a capital of 3 million pounds sterling. (Ibidem, .)

Talk about centralisation! The credit system, which has its center in the so-called national banks and the great money lenders and usurers about them, is an enormous centralisation, and gives to this class of parasites a fabulous power, not only to despoil periodically the industrial capitalists, but also to interfere into actual production in a most dangerous manner — and this gang knows nothing about production and has nothing to do with it. The Acts of 1844 and 1845 are proofs of the growing power of these bandits, who are joined by the financiers and stock jobbers.

Should any one still dream that these honorable bandits exploit national and international production only in the interest of production and of the exploited themselves, he will surely be taught better by the following homily on the high moral dignity of the bankers: “The bank establishments are religious and moral institutions. How often has not the fear of being seen by the vigilant and disapproving eye of his banker deterred the young

business man from seeking the society of noisy and extravagant friends? How anxious he is to stand well in the estimation of the banker, to appear always respectable! The knit brow of the banker has more influence over him than the moral preaching of his friends; does he not tremble to be suspected of being guilty of fraud or of the least false statement, for fear of causing suspicion, in consequence of which his banking accommodation might be restricted or cancelled? The advice of the banker is more important to him than that of the clergyman.” (G. M. Bell, a Scotch bank director, in *The Philosophy of Joint Stock Banking*, London, 1840, p and 47.)

CHAPTER XXXIV. THE CURRENCY PRINCIPLE AND THE ENGLISH BANK LAWS OF 1844.

[In a former work¹⁰⁵ the theory of Ricardo on the value of money as related to the prices of commodities has been analysed; we can, therefore, confine ourselves here to the indispensable. According to Ricardo, the value of metallic money is determined by the labor time incorporated in it, but only so long as the quantity of money stands in the right proportion to the quantity and price of the commodities to be handled. If the quantity of the money rises above this proportion, its value falls, the prices of commodities rise; if its quantity falls below the normal proportion, then its value rises and the prices of commodities fall — assuming all other circumstances to remain unchanged. In the first case the country, in which this excess of gold exists, will export the depreciated gold and import commodities; in the second case the gold will flow to those countries, in which it is held above its value, while the depreciated commodities flow from these countries to other markets, where they can obtain normal prices. “Since gold itself may become, both as coin and bullion, a token of value of greater or smaller magnitude than its bullion value, it is self-evident that convertible bank notes in circulation have to share the same fate. Although bank notes are convertible, i.e. their real value and nominal value agree, the aggregate currency consisting of metal and of convertible notes may appreciate or depreciate according as to whether it rises or falls, for reasons already stated, above or below the level determined by the exchange-value of the commodities in circulation and the bullion value of gold....This depreciation, not of paper as compared with gold, but of gold and paper together, or of the aggregate currency of a country, is one of the principal discoveries of Ricardo, which Lord Overstone and Co. pressed into their service and made a fundamental principle of Sir Robert Peel’s Bank legislation of 1844 and 1845.” (L. c. .)

We need not repeat here the demonstration of the incorrectness of this Ricardian theory, which is given in the same place. We are here merely interested in the way in which Ricardo’s theses were elaborated by that school of bank theorists, who dictated the above named Bank Acts of Peel.

“The commercial crises of the nineteenth century, namely, the great crises of 1825 and 1836, did not result in any new developments in the Ricardian theory of money, but they did furnish new applications for it. They were no longer isolated economic phenomena, such as the depreciation of the precious metals in the sixteenth and seventeenth centuries which interested Hume, or the depreciation of paper money in the eighteenth and early nineteenth centuries which confronted Ricardo; they were the great storms of the world market in which the conflict of all the elements of the capitalist process of production discharge themselves, and whose origin and remedy were sought in the most superficial and abstract sphere of this process, the sphere of money-circulation. The theoretical assumption from which the school of economic weather prophets proceeds, comes down in the end to the illusion that Ricardo discovered the laws governing the circulation of purely metallic currency. The only thing that remained for them to do was to subject to the same laws the circulation of credit and bank note currency.

“The most general and most palpable phenomenon in commercial crises is the sudden general decline of prices following a prolonged general rise. The general decline of prices of commodities may be expressed as a rise in the relative value of money with respect to all commodities, and the general rise of prices as a decline of the relative value of money. In either expression the phenomenon is described but not explained....The different wording leaves the problem as little changed as would its translation from German into English. Ricardo’s theory of money was exceedingly convenient, because it lends to a tautology the semblance of a statement of casual connection. Whence comes the periodic general fall of prices? From the periodic rise of the relative value of money. Whence the general periodic rise of prices? From the periodic decline of the relative value of money. It might have been stated with equal truth that the periodic rise and fall of prices is due to their periodic rise and fall....The tautology once admitted as a statement of cause, the rest follows easily. A rise of prices of commodities is caused by a decline of the value of money and a decline of the value of money is caused, as we know from Ricardo, by a redundant currency, i.e., by a rise of the volume of currency over the level determined by its own intrinsic value and the intrinsic value of the commodities. In the same manner, the general decline of prices of commodities is explained by the rise of the value of money above its intrinsic value in consequence of an inadequate currency. Thus, prices rise and fall periodically, because there is periodically too much or too

little money in circulation. Should a rise of prices happen to coincide with a contracted currency, and a fall of prices with an expanded one, it may be asserted in spite of those facts that in consequence of a contraction or expansion of the volume of commodities in the market which cannot be proved statistically, the quantity of money in circulation has, although not absolutely, yet relatively increased or declined. We have seen that according to Ricardo these universal fluctuations must take place even with a purely metallic currency, but that they balance each other through their alternations; thus, e.g., an inadequate currency causes a fall of prices, the fall of prices leads to an export of commodities abroad, this export causes again an import of gold from abroad, which, in its turn, brings about a rise of prices; the opposite movement taking place in case of a redundant currency, when commodities are imported and money is exported. But, since in spite of these universal fluctuations of prices which are in perfect accord with Ricardo's theory of metallic currency, their acute and violent form, their crisis form, belongs to the period of advanced credit, it is perfectly clear that the issue of bank notes is not exactly regulated by the laws of metallic currency. Metallic currency has its remedy in the import and export of precious metals, which immediately enter circulation and thus, by their influx or efflux, cause the prices of commodities to fall or rise. The same effect on prices must now be exerted by banks by the artificial imitation of the laws of metallic currency. If gold is coming in from abroad it proves that the currency is inadequate, that the value of money is too high and the prices of commodities too low, and, consequently, that bank notes must be put in circulation in proportion to the newly imported gold. On the other hand, notes have to be withdrawn from circulation in proportion to the export of gold from the country. That is to say, the issue of bank notes must be regulated by the import and export of the precious metals or by the rate of exchange. Ricardo's false assumption that gold is only coin, and that therefore all imported gold swells the currency, causing prices to rise, while all exported gold reduces the currency, leading to a fall of prices, this theoretical assumption is turned into a practical experiment of putting in every case an amount of currency in circulation equal to the amount of gold in existence. Lord Overstone (the banker Jones Loyd), Colonel Torrens, Norman, Clay, Arbutnot and a host of other writers, known in England as the adherents of the 'Currency Principle,' not only preached this doctrine, but with the aid of Sir Robert Peel succeeded in 1844 and 1845 in making it the basis of the present

English and Scotch bank legislation. Its ignominious failure, theoretical as well as practical, following upon experiments on the largest national scale, can be treated only after we take up the theory of credit.” (L. c. pages 255 to 259.)

The critique of this school was furnished by Thomas Tooke, James Wilson (in the “Economist” of 1844 to 1847) and John Fullarton. But how incompletely they themselves had seen through the nature of gold, and how unclear they were about the relation of money and capital, we have shown several times, particularly in chapter XXVIII of this volume. We quote here merely a few instances in connection with the transactions of the Committee of the Lower House of 1857 concerning Peel’s Bank Acts (B. C. 1857). — F. E.]

J. G. Hubbard, former Governor of the Bank of England, testifies: — 2400. “The effect of the gold exports...absolutely does not touch prices of commodities. It does, however, affect very much the prices of securities, because in proportion as the rate of interest changes, the values of the commodities impersonating this interest must necessarily be strongly affected.” — He presents two tables covering the years 1834 to 1843 and 1844 to 1853, which prove that the movement of prices of fifteen of the most important commercial articles was quite independent of the export and import of gold and of the rate of interest. On the other hand they prove a close connection between the export and import of gold, which is indeed the “representative of our capital seeking investment,” and the rate of interest.— “In 1847 a very large amount of American securities was transferred back to America, also Russian securities to Russia, and other continental papers to the countries from which we derived our imports of corn.”

The fifteen principal articles mentioned in the following tables of Hubbard are: Cotton, cotton yarn, cotton fabrics, wool, wool cloth, flax, linen, indigo, raw iron, white sheet metal, copper, tallow, sugar, coffee, silk.

I. From 1834-1843.

Date	Metal Reserve of the Bank	Market Rate of Discount	Of Fifteen Principal Articles		
			Prices Rose	Prices Fell	Prices Un- changed
1834, March 1	0,104,000	2.75%	—	—	—
1835, March 1	6,274,000	3.75%	7	7	1
1836, March 1	7,918,000	3.25%	11	8	1
1837, March 1	4,079,000	5%	5	9	1
1838, March 1	10,471,000	2.75%	4	11	—
1839, Sept. 1	2,684,000	6%	8	5	2
1840, June 1	4,571,000	4.75%	5	9	1
1840, Dec. 1	8,842,000	5.75%	7	6	2
1841, Dec. 1	4,873,000	5%	8	12	—
1842, Dec. 1	10,603,000	2.5%	2	13	—
1843, June 1	11,566,000	2.25%	1	14	—

II. From 1844-1853.

Date	Metal Reserve of the Bank	Market Rate of Discount	Of Fifteen Principal Articles		
			Prices Rose	Prices Fell	Prices Un- changed
1844, March 1	16,162,000	2.25%	—	—	—
1846, Dec. 1	13,227,000	4.25%	11	4	—
1848, Sept. 1	16,866,000	3%	7	8	—
1847, Sept. 1	9,140,000	6%	8	6	8
1850, March 1	17,126,000	2.25%	5	9	1
1851, June 1	13,705,000	1.75%	2	11	2
1852, Sept. 1	21,853,000	1.75%	9	5	1
1853, Dec. 1	15,093,000	5%	14	—	1

Hubbard remarked with reference to this: "Just as in the 10 years from 1834 to 1843, so in the years from 1844 to 1853 fluctuations in the gold of the bank were accompanied in every case by an increase or decrease of the loanable value of the money advanced at a discount; and on the other hand the changes in the prices of inland commodities showed a complete independence from the amount of the currency, as shown by the gold fluctuations of the Bank of England." (Bank Acts Report, 1857, II, pages 290 and 291.)

Since the demand and supply of commodities regulates their market-prices, it becomes evident here, that Overstone is wrong when he identifies the demand for loanable capital (or rather the discrepancies of its supply from demand), as expressed by the rate of discount, with the demand for actual "capital." The contention that the prices of commodities are regulated by the fluctuations in the quantity of the currency is now concealed under the

phrase that the fluctuations in the rate of discount express fluctuations in the demand for actual material capital, as distinguished from money-capital. We have seen that both Norman and Overstone actually made this contention before the same Committee, and that especially the latter was compelled to take refuge in very lame subterfuges, until he was finally cornered. (Chapter XXVI.) It is indeed the old fib that changes in the quantity of gold existing in a certain country, by increasing or reducing the quantity of the medium of circulation in that country, must raise or lower the prices of commodities in this country. If gold is exported, then, according to this currency theory, the prices of commodities must rise in the country importing this gold, and this must enhance the value of the exports of the gold exporting country on the market of the gold importing country; on the other hand, the value of the exports of the gold importing country would fall on the markets of the gold exporting country, while it would rise in the home country, which receives the gold. But in fact the reduction of the quantity of gold raises only the rate of interest, whereas an increase in the quantity of gold lowers the rate of interest; and were it not for the fact that the fluctuations of the rate of interest are taken into account in the determination of cost-prices, or in the determination of demand and supply, the prices of commodities would be wholly unaffected by them.

In the same report N. Alexander, Chief of a great Indian firm, expresses himself in the following manner on the heavy drains of silver to India and China about the middle of the fifties, partly in consequence of the Chinese Civil War, which checked the sale of English fabrics in China, and partly of the epidemic among silk worms in Europe, which reduced the output of silk in Italy and France considerably:

4337. “Is the drain toward China or India.”— “They send the silver to India, and with a goodly portion of it they buy opium, all of which goes to China in order to form a fund for the purchase of silk; and the condition of the markets in India (in spite of the accumulation of silver there) makes it more profitable for the merchant to send out silver than to send fabrics or other English factory goods.” — 4338. “Did not a heavy drain come out of France, by which we secured the silver?”— “Yes, a very heavy one.” — 4344. “Instead of importing silk from France and Italy, we ship it there in large quantities, both Bengal and Chinese.”

In other words, silver, the money metal of that continent, was sent to Asia instead of commodities, not because the prices of commodities had risen in

the country which had produced them (England), but because prices had fallen on account of overimport in that country which received them; and this in spite of the fact that the silver was received by England from France and had to be paid partly in gold. According to the Currency Theory prices should have fallen by such imports in England and risen in India and China.

Another illustration. Before the Lords' Committee (C. D. 1848-1857), Wylie, one of the first Liverpool merchants, testifies as follows: — 1994. “At the end of 1845 there was no better paying business and none that yielded greater profits [than cotton spinning]. The supply of cotton was large and good, workable cotton could be had at 4 d. per pound, and such cotton could be spun into good second mule twist No. 40 at about 8 d. total expense to the spinner. This yarn was sold in large quantities in September and October, 1845, and equally large contracts made for delivery at 10½ and 11½ d. per pound, and in some instances the spinners realised a profit which equalled the purchase price of the cotton.” — 1996. “The business remained profitable until the beginning of 1846.” — 2000. “On March 3, 1844, the cotton supply [672,042 bales] was more than double of what it is today [on March 7, 1848, when it was 301,070 bales], and yet the price was 1¼ d. per pound dearer.” [6¼ d. as against 5 d.] — At the same time yarn, good second mule twist No. 40, had fallen from 11½ to 12 d. to 9½ d. in October and 7¾ d. at the end of December, 1847; yarn was sold at the purchase price of the cotton from which it had been spun (Ibidem, No. 2021 and 2023). This proves the selfinterest of Overstone's wisdom to the effect that money is supposed to be “Dearer” when capital is “scarce.” On March 3, 1844, the bank rate of interest stood at 3%; in October and November, 1847, it rose to 8 and 9% and was still 4% on March 7, 1848. The prices of cotton were depressed far below that price which corresponded to the condition of the supply, by the complete stopping of sales and the panic with its correspondingly high rate of interest. The consequence of this was on the one hand an enormous decrease of the imports in 1848, and on the other a decrease of production in America; consequently a new rise in cotton prices in 1849. According to Overstone the commodities were too dear, because there was too much money in the country.

2002. “The recent deterioration in the condition of the cotton industry is not due to the lack of raw materials, since the price is lower, although the supply of raw cotton is considerably reduced.” But Overstone tangles himself up in a nice confusion of the price, or value, of commodities, with

the value of money, that is, the rate of interest. In his reply to question 2026, Wylie sums up his general judgment of the Currency Theory, on which Cardwell and Sir Charles Wood based in May, 1847, their contention that it would be necessary “to carry the Bank Act of 1844 out in its full scope.”— “These principles seem to me to be of a nature to give to money an artificially high value and to all commodities a ruinously low value.” — He says furthermore concerning the effects of this Bank Act on business in general: “Since four months’ bills of exchange, which are the regular drafts of manufacturing towns on merchants and bankers for purchased commodities intended for export to the United States, could no longer be discounted except at great sacrifices, the carrying out of orders was prevented to a large degree, until after the Government Letter of October 25.” [Suspension of Bank Acts], “when these four months’ bills became once more discountable.” (2097.) — We see, then, that the suspension of this Bank Act was felt as a relief also in the provinces. — 2102. “Last October nearly all American buyers, who purchase commodities here, immediately curtailed their purchases as much as possible; and when the news of the dearth of money reached America, all new orders stopped.” — 2134. “Corn and sugar were special cases. The corn market was affected by the crop prospects, and sugar was affected by the enormous supplies and imports.” — 2163. “Of our money obligations to America...many were liquidated by forced sales of consigned goods, and many, I fear, were liquidated by bankruptcies here.” — 2196. “If I remember correctly, as much as 70% interest was paid on our Stock Exchange in October, 1847.”

[The crisis of 1837, with its protracted aftereffects, which were followed in 1842 by a regular aftercrisis, and the self-interested blindness of the industrials and merchants, who would not notice any overproduction to save their lives — for such a thing was a nonsense and an impossibility according to vulgar economy — had ultimately accomplished that confusion of thought, which permitted the Currency School to put their dogma into practice on a national scale. The Bank legislation of 1844 and 1845 was passed.

The Bank Act of 1844 divides the Bank of England into an issue department for notes and a banking department. The issue department receives securities, principally government debts, to the amount of 14 millions and the entire metal treasure, which shall consist of not more than one-quarter in silver, and issues notes to the full amount of both of them. To

the extent that these are not in the hands of the public, they are held in the banking department and form its ever ready reserve together with the small amount of coin required for daily use (about one million). The issue department gives to the public gold for notes and notes for gold; the remainder of the transactions with the public is carried on by the banking department. The private banks authorised in England and Wales to issue their own notes retain this privilege, but their issue of notes is fixed; if one of these banks stops issuing its own notes, then the Bank of England may raise its uncovered amount of notes by two-thirds of the deposited allowance; in this way its allowance rose by 1892 from 14 to 16½ million pounds sterling (exactly 16,450,000 pounds sterling).

For every five pounds in gold, then, which leave the bank treasury, a five pound note returns to the issue department and is destroyed; for every five sovereigns going into the treasury a new five pound note passes into circulation. In this way Overstone's ideal paper circulation, which follows strictly the laws of metallic circulation, is practically carried out, and by this means crises are forever made impossible, according to the claims of the Currency advocates.

But in reality the separation of the Bank into two independent departments robbed the management of the possibility of disposing freely of its entire available means in critical moments, so that cases might occur, in which the banking department might be confronted with a bankruptcy, while the issue department still possessed several millions in gold and its entire 14 millions of securities untouched. And this could take place so much more easily, as there is one period in almost every crisis, when heavy exports of gold flow to foreign countries, which must be covered in the main by the metal reserve of the bank. But for every five pounds in gold, which then go to foreign countries, the circulation of the home country is deprived of one five pound note, so that the quantity of the currency is reduced precisely at a time, when the largest quantity of it is most needed. The Bank Act of 1844 thus directly challenges the commercial world to think betimes of laying up a reserve fund of bank notes on the eve of a crisis, in other words, to hasten and intensify the crisis; by this artificial intensification of the demand for money accommodation, that is for means of payment, and its simultaneous restriction of the supply, which take effect at the decisive moment, this Bank Act drives the rate of interest to a hitherto unknown high; hence, instead of doing away with crises, the Act rather intensifies them to a point, where

either the entire commercial world must go to pieces, or the Bank Act. Twice, on October 25, 1847, and on November 12, 1857, the crisis had risen to this culmination; then the government released the Bank from its limitation in the matter of issuing notes, by suspending the Act of 1844, and this sufficed in both cases to break the crisis. In 1847 the assurance sufficed, that bank notes would again be issued for first class securities, in order to bring to light the 4 to 5 millions of hoarded notes and throw them back into circulation; in 1857 the issue of notes exceeding the legal amount did not quite reach one million, and this was out for a very short time.

It may also be noted that the legislation of 1844 still shows traces of a recollection of the first twenty years of the nineteenth century, the time of the suspension of specie payments of the bank and the depreciation of notes. The fear that the notes might lose their credit is still plainly visible. But this is a very groundless fear, since already in 1825 the issue of some discovered old supply of one pound notes, which had been out of circulation, broke the crisis and proved, that even then the credit of the notes remained unshaken in times of the most universal and strong distrust. And this is easily explained. For the entire nation backs up these symbols of value with its credit. — F. E.]

Let us now listen to a few statements on the effect of the Bank Act. John Stuart Mill believes that the Bank Act of 1844 kept down overspeculation. Happily this wise man spoke on June 12, 1857. Four months later the crisis had broken out. He literally congratulates the “bank directors and the commercial public in general” on the fact that they “understand the nature of a commercial crisis far better than formerly, and the very great injury which they inflict upon themselves and the public by promoting overspeculation.” (B. C., 1857, No. 2031.)

Wise Mr. Mill thinks that, if one pound notes are issued “as loans to manufacturers and others, who pay wages...then the notes may get into the hands of others who spend them for purposes of consumption, and in this case the notes constitute in themselves a demand for commodities and may temporarily tend to promote a raise in prices.” Mr. Mill assumes, then, that the manufacturers will pay higher wages, because they pay them in paper instead of gold? Or does he believe that when a manufacture receives his loan in 100 pound notes and changes them for gold, then these wages would constitute less of a demand than they would when paid at the same time in one pound notes? And does he not know that, for instance, in certain mining

districts wages were paid in notes of local banks, so that several laborers together received a five pound note? Does this increase the demand for them? Or will the bankers advance money to the manufacturers more easily in small than in large notes, and make the loan larger?

[This peculiar fear of one pound notes on the part of Mill would be inexplicable, if his whole work on political economy did not show his eclecticism, which recoils from no contradictions. On the one hand he agrees in many things with Tooke against Overstone, on the other hand he believes in the determination of the prices of commodities by the quantity of the existing money. He is thus by no means convinced, that, all other circumstances remaining unchanged, a sovereign wanders into the vaults of the Bank for every one pound note issued. He fears that the quantity of the currency could be increased and thereby depreciated, that is, the prices of commodities might be enhanced. This and nothing else is concealed behind his above-mentioned apprehension. — F. E.]

Concerning the bipartition of the Bank, and the excessive precaution to safeguard the cashing of notes, Tooke expresses himself before the C. D. 1848-57 as follows:

The greater fluctuations of the rate of interest in 1847, as compared with 1837 and '39, are due merely to the separation of the Bank into two departments (3010).— “The security of the banknotes was not affected, neither in 1825, nor in 1837 nor in 1839 (3015). — The demand for gold in 1825 aimed only to fill out the vacant space created by the complete disavowal of the one pound notes of the provincial banks; this vacant space could be filled out only by gold, until the Bank of England also issued one pound notes (3022). — In November and December, 1825, not the least demand existed for gold to export (3023).

“As for a disavowal of the Bank at home and abroad, a suspension of the payment of dividends and deposits would have much more serious consequences than a suspension of payment on bank notes (3028).

3035. Would you not say that every circumstance, which would in the last instance endanger the convertibility of the bank notes, might create new and serious difficulties in a moment of commercial stringency?— “Not at all.”

In the course of 1847 “an increased issue of notes might, perhaps, have contributed to replenish the gold reserve of the Bank, as it did in 1825.” (3058).

Before the Committee on B. A. 1857, Newmarch testifies: 1357. “The first bad effect...of this separation of the two departments (of the Bank) and of the necessarily resulting bipartition of the gold reserve was that the banking business of the Bank of England, that is, that entire branch of its operations, which brought it into direct touch with the commerce of the country, was continued with only one-half of its former reserve. In consequence of this division of the reserve it happened that, as soon as the reserve of the banking department shrank in the least, the Bank was compelled to raise its rate of discount. This reduced reserve thus caused a series of abrupt changes in the rate of discount.”— “Of such changes there have been since 1844” [until June, 1857] “some 60 in number, whereas they amounted to hardly one dozen before 1844 within a similar period.”

Of special interest is the testimony of Palmer, who was a director of the Bank of England since 1811 and for a while its Governor, before the Lords’ Committee on C. D. 1848-57:

828. “In December, 1825, the Bank had retained only about 1,100,000 pounds sterling in gold. At that time it would have failed inevitably, if this act had existed then [meaning the Act of 1844]. In December it issued, I believe, 5 or 6 million notes in one week, and this relieved the panic of that time considerably.”

825. “The first period [since July 1, 1825], when the present bank legislation would have collapsed, if the Bank had attempted to carry its hitherto initiated transactions through, was on February 28, 1837. There were then from 3,900,000 to 4,000,000 pounds sterling in the possession of the Bank, and it would have retained no more than 650,000 pounds sterling in reserve. Another period is 1839, and it lasted from July 9 to December 5.”

— 826. “What was the amount of the reserve in this case?”— “The reserve was minus altogether 200,000 pounds sterling on September 5. On November 5, it rose to about 1 or 1½ millions.” — 830. “The Act of 1844 would have prevented the Bank from assisting the American business in 1837.”— “Three of the principal American firms failed....Nearly every firm in the American business was ruled out of credit, and if the Bank had not come to the rescue, I do not believe that more than one or two firms could have maintained themselves.” — 836. “The panic of 1837 is not to be compared with that of 1847. That of 1837 confined itself mainly to the American business.” — 838. (At the beginning of June the management of the Bank discussed the question, how to remedy the panic.) “Whereupon

some of the gentlemen defended the view...that the correct principle would be to raise the rate of interest, so that the prices of commodities would fall; in brief, to make money dear and commodities cheap, by which the foreign payment would be accomplished.” — 906. “The introduction of an artificial limitation of the powers of the Bank by the Act of 1844, in place of the old and natural limit of its powers, that is, the actual amount of its metal supply, makes business artificially difficult and thus effects prices in a way which was quite unnecessary without this Act.” — 968. “Under the effect of the Act of 1844 the metal reserve of the Bank, under ordinary circumstances, cannot be reduced materially below 9½ millions. This would create a pressure on prices and credit, which would bring about such a change in the foreign exchange rates, that the gold imports would rise and increase the amount of gold in the issue department.” — 996.

“Under the present limitation you [the Bank] have not command of silver which is required in times when silver is needed in order to affect foreign rates.” — 999. “What was the purpose of the rule limiting the silver supply of the Bank to one-fifth of its metal reserve?”— “I cannot answer this question!”

The purpose was to make money dearer; so was, aside from the Currency Theory, the separation of the two bank departments and the compulsion for Scotch and Irish banks to hold gold in reserve for the issue of notes beyond a certain amount. This brought about a decentralisation of the national metal supply, which rendered this supply less able to correct unfavorable bill rates. All these rules aim at a raise of the rate of interest: That the Bank of England shall not issue notes beyond 14 millions except against its gold reserve; that the banking department shall be managed like an ordinary bank, pressing the rate of interest down when money is plentiful and driving it up when money is scarce; the limitation of the silver supply, the principal means of rectifying the rates of bills on the continent and in Asia! the rules concerning the Scotch and Irish banks, who never need any money for export and yet must keep it now under the pretence of an actually imaginary convertibility of their notes. The fact is that the Act of 1844 caused for the first time in 1857 a run on the Scotch banks for gold. Nor did the new bank legislation make any distinction between a drain of gold toward foreign countries and a drain to inland markets, although their effects are evidently different. Hence the continual great fluctuations of the market rate of interest. With reference to silver Palmer says twice, No. 992 and 994, that the Bank can buy silver for

notes only when the rates on bills are favorable to England, so that silver is superfluous; for (1003) “the only purpose for which a considerable portion of the metal reserve may be kept in silver is that of facilitating foreign payments during the time when the rates on bills are against England.” — 1008. “Silver is a commodity which, being money in all the rest of the whole world, is for this reason the most fitting commodity...For this purpose” [payments abroad]. “Only the United States have taken exclusively gold during recent times.”

In his opinion the Bank would not have to raise the rate of interest above its old level of 5% in times of stringency, so long as no unfavorable bill rates draw the gold to foreign countries. Were it not for the Act of 1844, the Bank would then be able to discount all first class bills presented to it without any difficulty. [1018 to 20.] But with the Act of 1844, and in the condition, in which the Bank was in October, 1847, “there was no rate of interest which the Bank could ask from creditable firms, which they would not have paid willingly in order to continue their payments.” And this high rate of interest was precisely the purpose of the Act.

1029. “I must make a great distinction between the effect of the rate of interest on the foreign demand [for precious metal] and a raise of the rate of interest for the purpose of stemming a rush on the bank during a period of lacking credit inland.” — 1023. “Before the act of 1844, when the rates were in favor of England, and unrest, yea, a positive panic, reigned in the country, no limit was set to the issue of notes, by which alone this condition of stringency could be relieved.”

So speaks a man who had sat 39 years in the management of the Bank of England. Let us now hear a private banker, Twells who had been an associate of Spooner, Attwoods & Co. since 1801. He is the only one among all the witnesses before the B. C. 1857, who gives us an insight into the actual condition of the country and who sees the approach of the crisis. For the rest he is a sort of Little-Shilling-Man from Birmingham, for his associates, the brothers Attwood, are the founders of this school. (See A Contribution to the Critique of Political Economy, .) He testifies: 4488. “How do you think the Act of 1844 has operated?”— “Should I answer you as a banker, I would say that it has operated splendidly, for it has furnished to the bankers and [money-] capitalists of all sorts a rich harvest. But it has operated very badly for the honest and thrifty business man, who needs steadiness in discount, in order that he may make his arrangements with confidence....It has made the

lending of money a very profitable business.” — 4489. The Bank Act “Enables the London Stock Bank to pay to its stockholders 20 to 22%?” — “One of them paid recently 18%, and I believe another 20%; they have good grounds for standing determinedly by the Bank Act.” — 4490. “Small business men and respectable merchants, who have no large capital...it pinches them hard....The only means which I have of learning this is such a surprising quantity of their drafts, which are not paid. These drafts are always small, about 20 to 100 pounds sterling, many of them are not paid and go back for lack of payment to all parts of the country, and this is always a sign of stringency among — the small dealers.” — 4494. He declares that the business is not profitable now. His following remarks are important, because he saw the latent existence of the crisis, when none of the others suspected it as yet.

4494. “The prices in Mincing Lane keep up pretty well so far, but nothing is sold, one cannot sell anything at any price; one maintains himself at the nominal price.” — 4495 He relates the following case: A Frenchman sends to a broker in Mincing Lane commodities for 3,000 pounds sterling for sale at a certain price. The broker cannot make the price, the Frenchman cannot sell below his price. The commodities remain unsold, but the Frenchman needs money. The broker therefore makes him an advance of 1,000 pounds sterling in such a way, that the Frenchman draws a check of 1,000 pounds sterling for three months on the broker with his commodities for a security. At the end of the three months the bill becomes due, but the commodities are still unsold. The broker must then pay for the bill, and although he has security for 3,000 pounds sterling, he cannot raise them and gets into difficulties. In this way one drags down another. — 4496. “As for the heavy exports — when the business is depressed in the home market, it calls for the necessarily a heavy export.” — 4497. “Do you believe that the home consumption has decreased?” — “Very considerably — quite enormously — the small dealers are the best authority in this.” — 4498. “Nevertheless the imports are very large; does not that indicate a strong consumption?” — “Yes, if you can sell; but many warehouses are full of these things; in the example, which I have just related, 3,000 pounds sterling worth of commodities have been imported, which are unsalable.”

4514. “If money is dear, would you say that capital is then cheap?” — “Yes, sir.” — This man, then, is by no means of Overstone’s opinion that a high rate of interest is the same as dear capital.

The following shows how the business is carried on now. — 4516....”Others go in very heavily, do an enormous business in exports and imports, far beyond the limit to which their capital entitles them; there cannot be the least doubt about this. These people may be lucky in this; they may make great fortunes by some lucky stroke and pay up everything. This is in a large measure the system, by which nowadays a considerable portion of the business is carried on. Such people are willing to lose 20, 30 and 40% on a shipment; the next transaction may bring it back to them. If they fail in one thing after another, they are gone; and that is precisely the case which we have seen often enough of late; business firms have failed, without leaving one shilling’s worth of assets.”

4791. “The low rate of interest [during the last ten years] militates indeed against the bankers, but without laying the business books before you, I should have much difficulty in explaining to you, how much higher the profit [his own] is now than formerly. When the rate of interest is low, in consequence of excessive issues of notes, we have considerable deposits; when the rate of interest is high, it brings us direct profits.” — 4794. “When money may be had at a moderate rate of interest, we have more demand for it; we loan more; it works this way [for us, the bankers]. When it rises, we get more for it than when it is cheap; we get more than we ought to have.”

We have seen that the credit of the notes of the Bank of England is considered impregnable by all experts. Nevertheless the Bank Act absolutely ties up nine to ten millions in gold for the convertibility of these notes. The sacredness and inviolability of this reserve is here carried much farther than among the hoard makers of olden times. Mr. Brown (Liverpool) testifies, C. D. 1848-57, 2311: “Concerning the good derived at that time from this money [the metal reserve in the issue department], it might just as well have been thrown into the sea; for not the least bit of it could be used, without breaking the Act of Parliament.”

The building contractor, E. Capps, the same one who has been mentioned once before, and whose testimony is borrowed also to illustrate the modern building system in London (Volume II, chapter XII, pages 266 and 267), sums up his opinion of the Bank Act of 1844 in the following way (B. A. 1857): 5508. “You are, then, in general of the opinion that the present system [of bank legislation] is a very apt institution for bringing the profits of

industry periodically into the money bag of the usurer?”— “That is my opinion. I know that it has worked that way in the building business.”

We have already mentioned that the Scotch banks were pushed by the Bank Act of 1845 into a system approaching the English. They were placed under the obligation to hold gold in reserve for their issue of notes beyond a limit fixed for each bank. What the effect of this was, may be seen from the following testimony before the Bank Committee, 1857.

Kennedy, Director of a Scotch bank: 3375. “Was there anything in Scotland that might be called a circulation of gold, before the introduction of the Act of 1845?”— “Nothing of the kind.” — 3376. “Has an additional circulation of gold ensued since then?”— “Not in the least; the people dislike gold.” — 3450. “The sum of about 900,000 pounds sterling in gold, which the Scotch banks must keep since 1845, are in my opinion merely injurious and “absorb unprofitably an equal portion of the capital of Scotland.”

Furthermore Anderson, Director of the Union Bank of Scotland: 3558. “The only heavy demand for gold made on the part of the Scotch banks upon the Bank of England occurred on account of the foreign rates of exchange?”— “That is so; and this demand is not reduced by the fact that we keep gold in Edinburgh.” — 3590. “So long as we deposited the same amount of securities in the Bank of England” [or in the private banks of England] “we have the same power as before to create a drain of gold from the Bank of England.”

Finally we quote an article from the “Economist” (Wilson): “The Scotch banks keep unemployed amounts of cash with their London agents; these keep them in the Bank of England. This gives to the Scotch banks, within the limits of these amounts, command over the metal reserve of the bank, and here it is always in the place where it is needed, when foreign payments are to be made.” — This system was disturbed by the Act of 1845: “In consequence of the act of 1845 for Scotland a strong outpour of gold coin from the Bank of England has taken place lately, in order to meet a mere possible demand in Scotland, which would probably never occur. — Since that time a considerable amount finds itself tied up regularly in Scotland, and another considerable amount is continually under way between London and Scotland. If a time comes when a Scotch banker expects an increased demand for his notes, a box of gold is sent on from London; if this time is

past, the same box goes back to London, generally without having been opened.” (Economist, October 23, 1847.)

[And what does the father of the Bank Act, Banker Samuel Jones Loyd, alias Lord Overstone, say to all this?

He repeated even in 1848 before the Lords’ Committee on C. D. that “a money stringency and a high rate of interest, caused by a lack of sufficient capital, cannot be relieved by an increased issue of bank notes” (1514), in spite of the fact that the mere permission to increase the issue of notes, given by the government letter of October 25, 1847, had sufficed to break the point of the crisis.

He sticks to the idea that “the high rate of interest and the depressed condition of the manufacturing industry was the necessary consequence of the reduction of the material capital available for industrial and commercial purposes” (1604). And yet the depressed condition of the manufacturing industry had for months consisted in the fact that the material commodity-capital was filling the warehouses to overflowing and was almost unsalable; so that for this reason the material productive capital was wholly or partly fallow, in order not to produce still more unsalable commodity-capital.

And before the Bank Committee of 1857 he said: By a strict and prompt adherence to the principles of the Act of 1844 everything has passed off with regularity and ease, the money system is secure and unshaken, the prosperity of the country is undisputed, the public confidence in the Act of 1844 is daily gaining in strength. If this Committee desires still further practical proofs of the soundness of the principles on which this act rests, and of the beneficent consequences which it has guaranteed, then the true and sufficient answer is this: Look about you; consider the present condition of the business of this country; consider the satisfaction of the people; consider the wealth and prosperity of all classes of society; and then, after you have seen all this, this Committee will be able to decide, whether it will prevent a continuation of an Act, under which such success has been obtained.” (B. C. 1857, No. 4189.)

To this song of praise, which Overstone emitted before the Committee on July 14, replied the song of defiance on November 12, of the same year, in the shape of the letter to the management of the Bank, in which the government suspended the miracle-working law of 1844, in order to save what could still be saved. — F. E.]

CHAPTER XXXV. PRECIOUS METALS AND RATES OF EXCHANGE.

The Movements of the Gold Reserve.

CONCERNING the hoarding of notes in times of stringency we remark, that in such cases the hoarding of precious metals is repeated, which used to be resorted to in restless times during the most primitive conditions of society. The Act of 1844 is interesting in its effects for the reason that it seeks to transform all the precious metals existing in a certain country into currency; it seeks to identify a discharge of gold with a contraction of the currency and an incoming flood of gold with an expansion of the currency. And so it happened that the experiment proved the contrary. With one sole exception, which we shall mention immediately, the quantity of the circulating notes of the Bank of England never reached the maximum, since 1844, which it was authorized to issue. And the crisis of 1857 proved, on the other hand, that this maximum does not suffice under certain circumstances. From November 13, to 30, 1857, a daily average of 488,830 pounds sterling circulated above this maximum (B. A. 1858, p. XI). The legal maximum was at that time 14,475,000 pounds sterling plus the amount of the metal reserve in the vaults of the bank.

Concerning the outgoing and incoming tide of precious metals the following remarks are made:

A distinction should be made between the back and forth movements of the metal within the districts which do not produce any gold and silver, and on the other hand, between the flow of gold and silver from their sources of production to the different other countries and the distribution of this additional metal among these other countries.

Before the gold mines of Russia, California and Australia exerted their influence, the supply since the beginning of the nineteenth century sufficed only to replace the wornout coins, to satisfy the demand for articles of luxury, and to promote the exports of silver to Asia.

However, the silver exports of Asia increased extraordinarily since that time, owing to the Asiatic trade with America and Europe. The silver exported from Europe was largely replaced by the additional supply of gold. In the second place, a portion of the newly imported gold was absorbed by the internal money-circulation. It is estimated that up to 1857 about 30

millions in gold were added to the internal circulation of England.¹⁰⁶ Furthermore, the average volume of the metal reserves in all central banks of Europe and America increased since 1844. The increase of the inland money circulation also carried with it the circumstance, that in the period of stagnation following upon the panic the bank reserves grew more rapidly than before in consequence of the larger quantity of gold coins thrown out of inland circulation and held in a state of rest. Finally the consumption of precious metals for articles of luxury increased since the discovery of new gold deposits in consequence of the growing wealth.

Between the countries that do not produce any gold and silver, precious metals flow back and forth; the same country continually imports some, and just as continually exports some. It is only the predominance of this movement in one direction or the other which decides whether there is in the last instance a drain or an addition, since the merely oscillating and frequently parallel movements largely neutralise one another. But for this reason, so far as this result is concerned, the continuity and the mainly parallel course of both movements is overlooked. It is always assumed that a plus in the imports or a plus in the exports of precious metals appears only as an effect and concomitant of the proportion between the imports and exports of commodities, whereas they are at the same time an expression of the proportion between the exports and imports of precious metals themselves, independent of the trade of commodities.

The predominance of the imports over the exports, and vice versa, is measured on the whole by the increase or decrease of the metal reserve in the central banks. To what extent this scale of measurement is more or less exact, depends, of course, primarily on the degree to which the banking business in general is centralised. For on this premise turns the question, to what extent the precious metal hoarded in the so-called national banks represents the national metal reserve at all. But assuming this to be the case, the scale of measurement is not exact, because an additional import may be absorbed under certain circumstances by the inland circulation and the growing consumption of gold and silver in the making of articles of luxury; furthermore, because without an additional import a withdrawal of gold coin for inland circulation may take place and thus the metal reserve may decrease, even without a simultaneous increase of the export.

An export of metals assumes the aspect of a drain, when the movement continues for a long time, so that the decrease represents the tendency of the

movement and depresses the metal reserve of the bank considerably below its average level, down to about its average minimum. This minimum is in so far more or less arbitrarily fixed, as it is differently determined in every individual case by the legislation concerning the backing of notes, etc., by cash. Concerning the quantitative limits, which such a drain may reach in England, Newmarch testified before the Committee on B. A., 1857, Evidence No. 1494: "To judge by experience, it is very unlikely that the drain of metal as a result of some fluctuation in the foreign business will exceed three or four million pounds sterling." — In 1847 the lowest level of the gold reserve of the Bank of England, on October 23, showed a minus of 5,198,156 pounds sterling as compared to that of December 26, 1846, and a minus of 6,453,748 pounds sterling as compared to the highest level on August 29, 1846.

The functions of the metal reserve of the so-called national banks, which functions, however, do not by themselves regulate the magnitude of this reserve, for it may grow through a mere paralisation of internal commerce, are threefold: 1) It is a reserve fund for international payments, in one word a reserve fund of world money; 2) it is a reserve fund for the alternately expanding and contracting metal circulation of the inland markets; 3) it is a reserve fund for the payment of deposits and for the convertibility of notes, and this part of its function is connected with the function of the bank and has nothing to do with the functions of money as mere money. It may, therefore, also be touched by conditions, which affect every one of these three functions. As an international fund it, may be touched by the balance of payment, no matter by what causes this may be determined, and whatever may be its proportion to the balance of trade. As a reserve fund for the metal circulation of the inland market it may be touched by its expansion or contraction. The third function, that of a fund guaranteeing the convertibility of the notes, while it does not determine the independent movements of the metal reserve, has a double effect. If notes are issued, which replace the metallic money in the inland circulation (which may also consist of silver in countries where silver is a measure of value), then the second function of the reserve fund is eliminated. And a portion of the precious metal, which performed its function, will permanently wander into foreign countries. In this case no withdrawal of metallic money for inland circulation takes place, and this does away at the same time with the temporary augmentation of the metal reserve by the immobilised part of the

circulating metal coin. Furthermore, if a minimum of a metal reserve must be kept under all circumstances, it affects in a peculiar way the results of a drain or an addition of gold; it affects that part of the reserve, which the bank is compelled to maintain under all circumstances, or that part, which it seeks to get rid of as useless at a certain time. If the circulation were purely metallic and the banking system concentrated, the bank would have to consider its metal reserve likewise as a security for the payment of its deposits, and a drain of metal might then cause such a panic as was witnessed in Hamburg in 1857.

With the exception of 1837, the real crisis broke out always after the rates of exchange had been altered, that is, as soon as the import of precious metal had increased over the export.

In 1825 the real crash came after the drain of gold had ceased. In 1839 a drain of gold took place without bringing a crash. In 1847 the drain of gold ceased in April and the crash came in October. In 1857 the drain of gold to foreign countries had ceased since the beginning of November, and the crash did not come until later in November.

This stands out particularly in the crisis of 1847, when the drain of gold ceased already in April, after causing a slight preliminary crisis, and the real business crisis did not come until October.

The following evidence was given before the Secret Committee of the House of Lords on Commercial Distress, 1848. This evidence was not printed until 1857 (also quoted as C. D. 1848-57).

Evidence of Tooke. In April, 1847, a stringency arose, which strictly speaking equalled a panic, but was of relatively short duration and not accompanied by any commercial failures of importance. In October the stringency was far more intensive than at any time during April, an almost unheard of number of commercial failures taking place (2196). — In April the rates of exchange, particularly with America, compelled us to export a considerable amount of gold in payment for unusually large imports; only by an extreme effort did the bank stop the drain and drive the rates higher (2197). — In October the rates of exchange favored England (2198). — The change in the rates of exchange had begun in the third week of April (3000). — They fluctuated in July and August; since the beginning of August they always favored England (3001). — The drain of gold in August arose from a demand for internal circulation.

J. Morris, Governor of the Bank of England: Although the rate of exchange favored England since August, 1847, and an import of gold had taken place in consequence, the metal reserve of the bank decreased nevertheless. “2,200,000 pounds sterling went out to the country, as a result of inland demand.” (137) — This is explained on the one hand by an increased employment of laborers in railroad construction, on the other by a “desire of the bankers to possess their own gold reserve in times of crisis.” (147.)

Palmer, Ex-Governor and since 1811 a Director of the Bank of England: 684. “During the entire period from the middle of April, 1847 to the day of the suspension of the Bank Act of 1844 the rates of exchange were in favor of England.”

The drain of metal, which created in April, 1847, an independent money panic, was here, as always, but a precursor of the crisis and had already been turned back, when the crisis broke out. In 1839 a heavy drain of metal took place, for corn, etc., while the business was strongly depressed, but without any crisis and money panic.

As soon as the universal crises have spent themselves, the gold and silver, aside from an addition of new precious metals from the sources of production, distributes itself once more in such proportions as it showed in the form of the individual reserve of the various countries in a condition of equilibrium. Other circumstances remaining the same, its relative magnitude in every country will be determined by the role of that country in the world market. It flows away from the country which had more than its normal portion into some other country. These movements of outgoing and incoming metal restore merely its original distribution among the various national reserves. This redistribution, however, is brought about by the effects of different circumstances, which will be mentioned in our treatment of rates of exchange. As soon as the normal distribution is once more a fact, a stage of growth follows first, and then again a drain. [This last sentence applies, of course, only to England, as the center of the world’s money market. — F.E.]

The drains of metal are generally a symptom of a change in the condition of foreign commerce, and this change in its turn is a premonition that conditions are approaching a crisis.¹⁰⁷

The balance of payment may favor Asia against Europe and America.¹⁰⁸

An import of precious metals takes place to a point of predominance in two phases. On the one hand it takes place in the first phase of a low rate of interest, which follows upon a crisis and expresses a restriction of production; and then in the second phase, in which the rate of interest rises, without, however, attaining its medium level. This is the phase, in which returns come easy, commercial profit is large, and therefore the demand for loan capital does not grow in proportion to the expansion of production. In both phases, in which loan capital is relatively abundant, the superfluous addition of capital existing in the form of gold and silver, a form in which it can primarily serve only as loan capital, must seriously affect the rate of interest and with it the tone of the whole business.

On the other hand, a drain, a continued and heavy outpour of precious metals, takes place as soon as the returns are no longer easy, the markets overstocked, and the seeming prosperity held up only by credit; in other words, as soon as a very much increased demand for loan capital exists and the rate of interest has, for this reason, reached at least its medium level. Under these circumstances, which are reflected by the drain of precious metals, the effect of the continued withdrawal of capital in a form, in which it is directly loanable money-capital, is considerably intensified. This must have a direct influence on the rate of interest. But instead of restricting the credit business, the rise of the rate of interest extends it and leads to an overstraining of all its resources. This period, therefore, precedes the crash.

Newmarch is asked, B. A. 1857, No. 1520: "The amount of the circulating bills of exchange, then, rises with the rate of interest?"—"It seems so." — 1522. "In quiet, ordinary times the ledger is the actual instrument of exchange; but when difficulties arise, for instance, if the discount rate of the Bank is raised under circumstances such as I have mentioned...then the transactions resolve themselves quite of their own account into the drawing of bills; these bills are not only better suited to serve as a legal evidence of the making of some business transaction, but they are also better adapted to the purpose of making other purchases, and they are above all useful as a means of credit for taking up capital." — This is further intensified by the fact that as soon as signs of threatening conditions induce the bank to raise its rate of discount, which implies the possibility that the bank may at the same time cut down the running time of the bills to be discounted by it, the general apprehension is spread, that this will grow worse. Every one, and first of all the credit swindler, will

therefore strive to discount the future and have as many means of credit as possible at his command when the critical time comes. The above-mentioned reasons, then, amount in fact to this, that it is not the mere quantity of the imported or exported precious metals which exerts its influence in this capacity but that this quantity works its effect, first, by the specific character of precious metals of being capital in the form of money, and secondly, that it works like a feather, which, added to the weight on the scales, suffice to incline the oscillating balance definitely to one side, that is, it works this effect, because it arises under conditions, when a little excess decides in favor of one side or the other. Without these reasons it would be quite inexplicable, why a drain of gold amounting to about five or eight million pounds sterling, and this is the limit according to present experience, should be able to exert any considerable influence. This small minus or plus of capital, which seems insignificant even compared to the 70 million pounds in gold which circulate on an average in England, is a vanishing magnitude in a production of such volume as the English.¹⁰⁹

But it is just the development of the credit and banking business, which tends on the one hand to press all money-capital into the service of production (or what amounts to the same, to convert all money incomes into capital), and which on the other hand reduces the metal reserve to a minimum in a certain phase of the cycle, so that it can no longer perform the functions for which it is intended. It is the developed credit and banking system, which creates this oversensitiveness of the whole organism of the reserve below or above its average level is a relatively insignificant matter. On the other hand, even a very considerable drain of gold is relatively ineffective, unless it arises in the critical period of the industrial cycle.

In this explanation we have not considered the cases, in which a drain of gold takes place as a result of crop failures, etc. In this case the great and sudden disturbance of the equilibrium of production, whose expression this drain is, requires no further explanation of its effects. These effects are so much greater, the more such a disturbance begins in a period, in which production works under high pressure.

We have also left out of consideration the function of the metal reserve as a security for the convertibility of the bank notes and as the cardinal point of the credit system. The central bank is the pivot of the credit system. And the metal reserve in its turn is the pivot of the bank.¹¹⁰

The transition from the credit system to the monetary system is necessary, as I have already shown in Volume I, chapter III, under the head of “Means of Payment.” That the greatest sacrifices of real wealth are necessary, in order to maintain the metallic basis in a critical moment, has been admitted by both Tooke and Loyd-Overstone. The controversy turns merely around a plus or minus, and around the more or less rational treatment of the inevitable.¹¹¹ A certain quantity of metal, insignificant compared with the total production, is admitted to be the pivotal point of the system. Hence its beautiful theoretical dualism, aside from the appalling demonstration of this character in its capacity as the pivotal point of crises. So long as enlightened bourgeois economy treats of “Capital” in its official capacity, it looks down upon gold and silver with the greatest disdain, considering them as the most immaterial and useless forms of wealth. But as soon as it treats of the banking system, everything is reversed, and gold and silver become capital par excellence, for whose preservation every other form of capital and labor is to be sacrificed. But how are gold and silver distinguished from other forms of wealth? Not by the magnitude of their value, for this is determined by the quantity of labor materialised in them; but by the fact that they represent independent incarnations, expressions of the social character of wealth. [The wealth of society exists only as the wealth of private individuals, who are its owners. It shows its social capacity only in the fact that these individuals exchange the qualitatively different use-values mutually for the satisfaction of their wants. Under the capitalist production they can do so only by means of money. Thus the wealth of the individual is realised as a social wealth only by means of money. In money, in this thing, the social nature of this wealth is incarnated. — F. E.] This social existence assumes the aspect of a world beyond, of a thing, matter, commodity, by the side of and outside of the real elements of social wealth. So long as production is in a state of flux, this is forgotten. Credit, likewise, in its capacity as a social form of wealth, crowds money out and usurps its place. It is the faith in the social character of production, which gives to the money-form of products the aspect of something disappearing and ideal. But as soon as credit is shaken — and this phase always appears of necessity in the cycles of modern industry — all the real wealth is to be actually and suddenly transformed into money, into gold and silver, a crazy demand, which, however, necessarily grows out of the system itself. And all the gold and silver, which is supposed to satisfy

these enormous demands, amounts to a few millions in the cellars of the Bank.¹¹²

In the effects of the gold drains, then, the fact that production as a social process is not subject to social control is strikingly emphasized by the existence of the social form of wealth outside of it as a separate thing. The capitalist system of production, it is true, shares this with former systems of production, so far as they rest on the trade with commodities and private exchange. But only in it does this become apparent in the most striking and grotesque form of the most absurd contradiction and nonsense, because, in the first place, production for the direct use of the producers is most completely abolished under the capitalist system, so that wealth exists only as a social process expressed by the interrelations of production and circulation; and in the second place, because capitalist production forever strives to overcome this metallic barrier, the material and phantastic barrier of wealth and its movements, in proportion as the credit system develops, but forever breaks its head on this same barrier.

In the crisis the demand is made, that all bills of exchange, securities, and commodities shall be simultaneously convertible into bank money, and this whole bank money consists of gold.

The Rate of Exchange.

[The barometer for the international movement of the money metals is the rate of exchange. If England has more payments to make to Germany than Germany to England, the price of marks, expressed in sterling, rises in London, and the price of sterling, expressed in marks, falls in Hamburg and Berlin. If this overbalance of monetary obligations of England toward Germany is not equalised, for instance, by over purchases of Germany in England, the sterling price for marks on bills of exchange on Germany must rise to a point, where it will pay to send metal (gold coin or bullion) from England to Germany in payment of obligations, instead of sending bills of exchange. This is the typical course of things.

If this export of precious metals assumes a larger scope and lasts longer, then the English bank reserve is touched, and the English money market, with the bank of England at the head, must take precautionary measures. These consist mainly, as we have already seen, in the raising of the rate of interest. When the drain of gold is considerable, the money market is always difficult, that is, the demand for loan capital in the form of money

exceeds the supply by far, and the raising of the rate of interest follows quite naturally from this; the rate of discount fixed by the Bank of England corresponds to this condition and asserts itself on the market. However, there are cases, when the drain of metal is due to other than the ordinary combinations of business (for instance, to loans of foreign states, investment of capital in foreign countries, etc.), when the London money market in that respect does not justify such an effective raise of the rate of interest; in that case the Bank of England must first make money “scarce” by heavy loans in the “open market” and thus create artificially a condition, which justifies a raise of the rate of interest, or renders it necessary; a maneuver, which becomes from year to year more difficult for it. — F. E.]

How this raising of the rate of interest affects the rates of exchange, is shown by the following testimony before the Committee of the Lower House concerning bank legislation in 1857 (quoted as B. A., or B. C., 1857.)

John Stuart Mill: 2176. “When the business has become difficult...a considerable fall in the price of securities takes place...foreigners order the buying of railroad shares here in England, or English owners of foreign railroad shares sell them to foreign countries...to that extent the transfer of gold is avoided.” — 2182. “A large and rich class of bankers and dealers in securities, by whom the equalisation of the rate of interest and the equalisation of the commercial barometric pressure between the different countries is generally accomplished...is always on the lookout for the purchase of securities, which promise a rise in price...the proper place to buy them will be the country which sends gold abroad.” — 2183. “These investments of capital took place to a large extent in 1847, enough to reduce the drain of gold.”

J. G. Hubbard, Ex-Governor, and since 1838 a Director of the Bank of England: 2545. “There are a large number of European securities...which have a European circulation in all the various money markets, and these papers, as soon as they fall by one or two per cent. in one market, are at once brought up in order to be transferred to markets, where their value has still maintained itself.” — 2565. “Are not foreign countries considerably in debt to merchants in England?” — ...”Very considerably.” — 2566. “The collection of these debts might, therefore, suffice by itself to explain a very large accumulation of capital in England?” — “In the year 1847 our position

was finally restored by our drawing a line through so and so many millions, which America and Russia formerly owed to England.” [England owed these same countries at the same time “so and so many millions” for corn and did not forget to “draw a line” also through the greater portion of these by the bankruptcy of the English debtors. See the report on Bank Acts, 1857, in chapter XXX of this work.] — 2572. “In 1847 the rate of exchange between England and Petersburg stood very high. When the government letter was issued, which authorized the Bank of England to issue bank notes without adhering to the legally prescribed limit of 14 millions [beyond the gold reserve], the condition was that the discount should be kept at 8%. At that moment, and at that rate of discount, it was a profitable business to have gold shipped from Petersburg to London and to lend it out after its arrival at 8% until the three months’ bills of exchange should become due, which had been drawn against the sold gold.” — 2573. “In all operations with gold many points must be taken into consideration; it depends on the rate of exchange and on the rate of interest, at which money may be invested until the bills drawn against it become due.”

Rate of Exchange with Asia.

The following points are important, partly because they show that England must take refuge to other countries, when its rate of exchange with Asia is unfavorable. These are countries, whose imports from Asia are paid by way of England. On the other part they are important, because Mr. Wilson makes once more the silly attempt here, to identify the effect of an export of precious metal on the rates of exchange with the effect of an export of capital in general upon these rates; the export being in either case not for the purpose of paying or buying, but of investing capital. In the first place it goes without saying, that whether so and so many millions of pounds sterling are sent to India in precious metals or railroad rails, in order to be invested in railroads there, these are merely two different forms of transferring the same amount of capital to another country. And this is a form of transfer, which does not enter into accounts of the ordinary mercantile businesses, and for which the exporting country expects no other returns than later on the annual revenue from the income of these railroads. If this export is made in the form of precious metal, it will exert a direct influence upon the money market and with it upon the rate of interest of the country exporting this precious metal, at least under the previously outlined conditions, if not necessarily under all circumstances, since precious metal

is directly loanable money-capital and the basis of the entire money-system. This export also affects directly the rate of exchange. For precious metal is exported only for the reason and to the extent that the bills of exchange, say, on India, which are offered in the London money market, do not suffice for the making of these extra payments. In other words, there is a demand for Indian bills of exchange which exceeds their supply, and so the rates turn for a time against England, not because it is in debt to India, but because it has to send extraordinary sums to India. In the long run such a shipment of precious metal to India must have the effect of increasing the Indian demand for British goods, because it indirectly increases the consuming power of India for European goods. But if the capital is shipped in the shape of rails, etc., it cannot have any influence on the rates of exchange, since India has no return payment to make for it. For the same reason this need not have any influence on the money market. Wilson seeks to establish the fact of such an influence by declaring that such an extra expenditure will bring about an extra demand for money accommodation and will thus influence the rate of interest. This may be the case; but to maintain that it must take place under all circumstances is totally wrong. No matter whether the rails are shipped and laid on English or Indian soil, they represent nothing else but a definite expansion of English production in a definite sphere. To contend that an expansion of production, even to a large volume, cannot take place without driving the rate of interest higher, is absurd. The money accommodation may grow, that is, the amount of business transacted by operations of credit; but these operations may increase also while the rate of interest remains unchanged. This was actually the case during the railroad mania in England during the forties. The rate of interest did not rise. And it is evident, that, so far as actual capital, in this case commodities, are concerned, the effect on the money market will be just the same, whether these commodities are intended for foreign countries or for inland consumption. A difference could be discovered only in the case that the investment of capital on the part of England in foreign countries would have a restraining influence upon its commercial exports, that is, exports for which payment must be made in return, or to the extent that these investments of capital are general symptoms indicating the overstraining of credit and the beginning of swindling operations.

In the following Wilson asks questions and Newmarch answers them.

1786. “You said before, with reference to the silver demand for Eastern Asia, that in your opinion the rates of exchange with India are in favor of England, in spite of the considerable wealth of metal continually sent to Eastern Asia; have you any reasons for this?”—” To be sure....I find that the actual value of the exports of the United Kingdom to India amounted to 7,420,000 pounds sterling in 1851; to this must be added the amount of the bills of exchange of the India House, that is, the funds which the East Indian Company draws from India for the payment of its own expenses. These drafts amounted in that year to 3,200,000 pounds sterling; so that the total exports of the United Kingdom to India amounted to 10,620,000 pounds sterling. In 1855 the actual value of the exports of commodities had risen to 10,350,000 pounds sterling; the drafts of the India House were 3,700,000 pounds sterling; the total exports therefore 14,050,000 pounds sterling. For 1851, I believe, we have no means of ascertaining the actual value of the imports of commodities from India to England; but we have for 1854 and 1855. In 1855 the entire actual value of these imports of commodities from India to England was 12,670,000 pounds sterling and this sum, compared to the 14,050,000 pounds sterling, leaves a balance in favor of England, in the direct commerce between the two countries, amounting to 1,380,000 pounds sterling.”

Thereupon Wilson remarks that the rates of exchange are also touched by the indirect commerce. For instance, the exports from India to Australia and North America are covered by drafts on London, and therefore affect the rate of exchange quite in the same way as though the commodities had gone directly from India to England. Furthermore, when India and China are taken together, the balance is against England, since China has continually heavy payments to make to India for opium, and England has to make payment to China, and the amounts go by this circuitous route to India. (1787, 1788.)

1789. Wilson asks now, whether the effect on the rates of exchange will not be the same, no matter whether the capital goes out in the form of iron rails or locomotives, or in the form of metal coin. Newmarch gives the correct answer: The 12 million pounds sterling, which have been sent during the last years to India for railroad construction served to buy an annual income, which India has to pay at regular terms to England. So far as

any immediate effect on the precious metal market is concerned, the investment of 12 million pounds sterling can exert any influence only to the extent that metal had to be sent out for an actual investment in money.

1797. Weguelin asks: “If no returns are made for these rails, how can it be said that they affect the rate of exchange?”— “I do not believe that that portion of the expenditure, which is sent abroad in the form of commodities, affects the stand of the rates of exchange...the stand of the rates between two countries is, one may say exclusively, affected by the quantity of the obligations or bills of exchange offered in opposition to them in another country; that is the rational theory of the rate of exchange. As for the shipment of those 12 millions, they were in the first place subscribed here; now, if the business were such, that these entire 12 millions would be deposited in cash in Calcutta, Bombay and Madras...this sudden demand would strongly affect the price of silver, just as would be the case if the East India Company were to announce tomorrow, that it would increase its drafts from 3 millions to 12 millions. But one-half of these 12 millions is invested...in the purchase of commodities in England...iron rails and lumber and other materials...it is an investment of English capital, in England itself, for a certain kind of commodities to be shipped to India, and that ends the matter.” — 1798. Weguelin: “But the production of these commodities of iron and wood required for the railroads produces a heavy consumption of foreign commodities, and this could affect the rate of interest, could it not?”— “Assuredly.”

Wilson thinks now, that iron largely represents labor, and that the wages paid for this labor largely represent imported goods (1799), and then he asks further:

1801. “But speaking quite generally: If the commodities, which have been produced by means of the consumption of these imported commodities, are sent out in such a way, that we do not receive any returns for them, either in products or otherwise, would not that have the effect of making the rates of exchange unfavorable for us?”— “This principle is exactly what happened in England during the time of the great railway enterprises . For three or four years in succession you invested 30 million pounds sterling in railroads and almost the whole in wages. You have

maintained during three years in the construction of railroads, locomotives, cars, stations, a greater number of people than in all factory districts together. These people...expended their wages in the purchase of tea, sugar, liquor and other foreign commodities; these commodities must be imported; but it is certain that during the time that this great investment was being made, the rates of exchange between England and other countries were not materially disturbed. No drain of precious metal took place, on the contrary, rather an addition.”

1802. Wilson insists that with a settled balance of trade and par rates between England and India the extra shipment of iron and locomotives “must affect the rate of exchange.” Newmarch cannot see it that way, so long as the rails are sent out as an investment of capital and India has no payment to make for them in one form or another; he adds: “I agree with the principle that no country can in the long run have an unfavorable rate of exchange with all countries, with whom it deals; an unfavorable rate of exchange with one country necessarily produces a favorable one with another.” — Wilson retorts with this triviality: 1803. “But would not a transfer of capital be the same, whether the capital were sent in this form or that?” — “So far as an indebtedness is concerned, yes.” — 1804. “Then, whether you send out precious metal or commodities, the effect of railroad construction in India on the market of capital here would be the same and would increase the value of capital just as though the whole had been sent out in precious metal?”

If the prices of iron did not rise, it was certainly a proof that the “value” of the “capital” contained in the rails had not been increased. What is wanted is the value of money-capital, of the rate of interest. Wilson would like to identify money-capital with capital in general. The simple fact is, primarily, that 12 millions for Indian railroads are subscribed in England. This is a matter which has nothing directly to do with the rates of exchange, and the destination of the 12 millions is also immaterial for the money market. If the money market is in good condition, it need not produce any effect at all on it, just as the English railroad subscriptions in 1844 and 1845 left the money market untouched. If the money market is already somewhat difficult, then the rate of interest might indeed be affected by it, but certainly only in an upward direction, and this would have a favorable

effect for England on the rates of exchange according to Wilson's theory, that is, it would work against the tendency to export precious metal; if not to India, then to some other country. Mr. Wilson jumps from one thing to another. In question 1802 the rates of exchange are supposed to be affected, in question 1804 the "value of capital," two very different things. The rate of interest may affect the rates of exchange, and the rates may affect the rate of interest, but the rate of interest may be stable while the rates of exchange fluctuate, and the rates of exchange may be stable while the rate of interest fluctuates. Wilson cannot understand, that the mere form, in which capital is shipped abroad, should make such a difference in the effect, that is, that the difference in the form of capital should have such an effect, not to mention its money form, which runs very much counter to the enlightened economy. Newmarch answers Wilson's question onesidedly inasmuch as he does not point out that he has jumped so suddenly and without reason from the rate of exchange to the rate of interest. Newmarch answers question 1804 uncertainly and doubtfully: "No doubt, if 12 millions are to be raised, it is immaterial, so far as the general rate of interest is concerned, whether these 12 millions are to be sent out in precious metals or in materials. I believe, however" [a fine transition, this however, when he intends to say the exact opposite] "that this is not quite immaterial" [it is immaterial, but, however, it is not material] "because in the one case the six million pounds sterling would return immediately; in the other case they would not return so quickly. Therefore it would make some" [what definiteness!] "difference, whether the six millions were invested here at home or sent entirely abroad." What does he mean by saying that the six millions would return immediately? To the extent that the six million pounds sterling have been spent in England, they exist in rails, locomotives, etc., which are shipped to India, whence they do not return, and their value returns very slowly through a sinking fund, whereas six millions in precious metals may return very quickly in their natural form. To the extent that six millions have been spent in wages, they have been consumed; but the money, in which they were paid, circulates in the country the same as ever or forms a reserve. The same is true of the profits of the producers of iron rails and of that portion of the six millions which makes good their constant capital. This ambiguous phrase of the return of values is used by Newmarch only in order to avoid saying directly: The money has remained in the country, and so far as it serves as loanable money-capital the difference for the money-market (aside

from the possibility that the circulation might have swallowed more hard cash) is only this, that it is spent for the account of A instead of B. An investment of this kind, where the capital is transferred to other countries in commodities, not in precious metals, cannot affect the rate of exchange, unless the production of these exported commodities requires an extra-import of other foreign commodities, and this, at any rate, does not affect the rate of exchange with the country in which the exported capital is invested. This production is not intended to settle for this extra import. The same takes place in every export on credit, no matter whether it be intended for investment as capital or for ordinary purposes of commerce. Besides, such an extra import may also cause a reaction in the way of an extra demand for English goods, for instance, on the part of the colonies or of the United States.

Before that Newmarch said that owing to the drafts of the East India Company the exports from England to India were larger than the imports. Sir Charles Wood cross-examines him on this score. This excess of the English exports to India over the imports from India is actually due to imports from India, for which England does not pay any equivalent. The drafts of the East India Company (now of the British government) resolve themselves into a tribute levied on India. For instance, in 1855 the imports from India to England amounted to 12,670,000 pounds sterling; the English exports to India amounted to 10,350,000 pounds sterling; balance in India's favor 2,250,000 pounds sterling. "If the matter were exhausted with this, then these 2,250,000 pounds sterling would have to be remitted to India in some form. But then come the invitations from the India House. The India House announces that it is in a position to issue drafts on the different presidencies in India to the amount of 3,250,000 pounds sterling. [This amount was levied for the London expenses of the East India Company and for the dividends due to the stockholders.] And this liquidates not merely the balance of 2,250,000 pounds sterling, which arose in a business way, but gives besides a surplus of one million." (1917.)

1922. Wood: "Then the effect of these drafts of the India House is not to increase the exports to India, but to reduce them to that extent?" [He means to say to reduce the necessity of covering the imports from India by exports to India to the same amount.] Mr. Newmarch explains this by saying that

the British export for these 3,700,000 pounds sterling a “good government” to India (1925). Wood, knowing very well the kind of “good government” exported to India by the British, having been Minister to India, replies correctly and ironically: 1926. “Then the exports, which, as you say, are caused by the India House drafts, are exports of good government, and not of commodities.” — Since England exports a good deal “in this way” in the shape of “good government” and for investment of capital in foreign countries, things which are quite independent of the ordinary run of business, tributes which consist either in payment for “good government” or in revenues from capital invested in the colonies or elsewhere, tributes for which it does not have to pay any equivalent, it is evident, that the rates of exchange are not affected, when England simply consumes these tributes without making any exports in return for them. Hence it is also evident that the rates of exchange are not affected, when it reinvests these tributes, not in England, but productively or unproductively in foreign countries; for instance, when it sends ammunition to the Crimea with them. Moreover, to the extent that the imports from abroad pass into the revenue of England — of course, they must first have been paid, either in the form of tributes for which no equivalent return is made, or by exchanging things for these tributes before they have been paid, or by the ordinary course of commerce — England can either consume them or reinvest them as capital. Neither the one nor the other thing touches the rates of exchange, and this is what Wilson overlooks. Whether a domestic or a foreign product forms a part of the revenue — and this last case requires merely an exchange of domestic for foreign products — the consumption of this revenue, be it productive or unproductive, alters nothing in the rates of exchange, even though it may alter the scale of production. The following remarks should be judged by the foregoing explanation:

1934. Wood asks Newmarch, how the shipment of war supplies to the Crimea would affect the rates of exchange with Turkey. Newmarch replies: “I do not see, that the mere shipment of war supplies would necessarily affect the rates of exchange, but the shipment of precious metals would surely affect these rates.” In this case he distinguishes capital in the form of money from capital in other forms. But now Wilson asks:

1935. “If you promote an export on a large scale of some article for which no corresponding import takes place, you do not pay the foreign debts, which you have contracted by your imports, and for this reason you must affect the rates of exchange by these transactions, since the foreign debts are not paid, because your export has no corresponding import. — This is true of countries in general.” [Mr. Wilson forgets, that there are very considerable imports into England, for which no corresponding exports have ever taken place, except in the form of “good government” or of formerly exported capital for investment; at any rate imports which do not pass into the regular commercial movement. But these imports are again exchanged, for instance, for American products, and the fact that American goods are exported without any corresponding imports does not alter the fact that the value of these imports may be consumed without any equivalent return abroad; they have been received without being balanced by any corresponding exports, and may also be used up without entering into the balance of trade. On the other hand, if these imports have already been paid by you, for instance, by credit given to foreign countries, then no debt is contracted through this, and the question has nothing to do with the international balance; it resolves itself into productive and unproductive expenditures, no matter whether the products so used are domestic or foreign.]

This lecture of Wilson’s amounts to saying that every export without a corresponding import is at the same time an import without a corresponding export, because foreign, hence imported, commodities enter into the production of the exported article. The assumption is that every export of this kind is based on some unpaid import, or creates it, resulting in a debt to a foreign country. This is wrong, even aside from the two following circumstances. 1) England receives imports free of charge, for which it pays no equivalent, such as a portion of its Indian imports. It may exchange these for American imports, and may export the latter without any imports to counterbalance them; but at any rate, so far as this value is concerned, it has only exported something that did not cost it anything. 2) England may have paid for imports, for instance American imports, which form additional capital; if it consumes these unproductively, for instance, using them as war materials, this does not constitute any debt towards America and does not affect the rates of exchange with America. Newmarch contradicts himself in

numbers 1934 and 1935, and Wood calls his attention to this, in number 1938: “If no portion of the commodities employed in the manufacture of articles, which we export without receiving any returns [war materials], comes from the country into which these articles are sent, how does that touch the rate of exchange with that country? Suppose that commerce with Turkey is in the ordinary condition of equilibrium; how is the rate of exchange between us and Turkey affected by the export of war materials to the Crimea?” — Here Newmarch loses his equanimity; he forgets that he has answered the same simple question correctly in No. 1934, and says: “We have, it seems to me, exhausted the practical question, and we are now getting into a very high region of metaphysical discussion.”

[Wilson has still another version of his claim, that the rate of exchange is affected by every transfer of capital from one country to another, no matter whether this takes place in the form of precious metals or of commodities. Wilson knows, of course, that the rate of exchange is affected by the rate of interest, particularly by the relation of the rates of interest current in any two countries whose rates of exchange are under discussion. If he can now demonstrate that any surplus of capital, and in the first place commodities of all kinds, including precious metals, contribute their share to influencing the rate of interest, then he makes a step nearer to his goal; a transfer of any considerable portion of this capital to some other country must then change the rate of interest in both countries, in opposite directions, and this must alter in a secondary way the rate of exchange between both countries. — F. E.]

He says, then, in the “Economist,” 1847, page 475, which he edited at that time:

“It is evident, that such a surplus of capital, indicated by large supplies of all kinds, including precious metals, must lead necessarily, not only to lower prices of commodities in general, but to a lower rate of interest for the use of capital.”

“If we have a stock of commodities on hand, large enough to supply the country for the coming two years, then a command of these commodities for a given period may be had at a much lower rate than if it would last only for two months.”

All loans of money, in whatever form they may be made, are merely transfers of the command over commodities from one to another. If, therefore, commodities are superabundant, then the money interest must be low, if they are scarce, it must be high.”

“If commodities come in more abundantly, the number of sellers compared to the number of buyers must increase, and in proportion as the quantity exceeds the needs of the direct consumers, an ever larger portion must be stored up for later use. Under these circumstances an owner of commodities will sell at lower conditions on future payment, or on credit, than he would if he were sure that his whole stock would be sold within a few weeks.”

Our comment on sentence No. I, is that a strong addition to the precious metals may be made while production is simultaneously contracted, which is always the case in the period after a crisis. In the subsequent phase precious metals may come in from countries that produce above all precious metals; the imports of other commodities are generally balanced by the exports during this period. In these two phases the rate of interest is low and rises but slowly; we have already explained the reason for this. This low rate of interest may be explained everywhere without any influence of any “Large supplies of any kind.” And how is this influence to take place? The low price of cotton, for instance, renders possible the high profits of the spinners, etc. Now why is the rate of interest low? Surely not, because the profit, which may be made on borrowed capital, is high. But simply and solely, because under existing conditions the demand for loan capital does not grow in proportion to this profit; in other words, because loan capital has a different movement than industrial capital. What the “Economist” wants to prove is exactly the reverse, namely that the movements of loan capital are identical with those of industrial capital.

Comment on sentence No. 2). If we reduce the absurd assumption of a stock for two years ahead to a point where it begins to take on some meaning, it signifies that the markets are overstocked. This would cause a falling of prices. Less would have to be paid for a bale of cotton. This would by no means justify the conclusion, that the money which is to be used for the payment of this cotton, is more easily borrowed. For this depends on the condition of the money market. If money can be borrowed

more easily, it can be so only because the commercial credit is in such shape, that it has to make less use of bank credit than ordinarily. The commodities overcrowding the market are means of subsistence or means of production. The low price of both increases in this case the profit of the industrial capitalist. Why should these low prices depress the rate of interest, unless it be through the contrast (not the identity) between the abundance of industrial capital and the scarcity of the demand for loan capital? The circumstances are such, that the merchant and the industrial capitalist can more easily give credit to one another; owing to this facilitation of commercial credit, neither the industrial nor the merchant need much bank credit; hence the rate of interest can be low. This low rate of interest has nothing to do with the increase of precious metals, although both of them may run parallel to each other and the same causes, which bring about the low prices of articles of import, may also produce a surplus of precious metals. If the import market were really overcrowded, it would prove a decrease of the demand for imported articles, and this would be inexplicable at low prices, unless it be attributed to a contraction of industrial production at home; but this, again, would be inexplicable, so long as there is an over importation at low prices. All these absurdities are brought forward for the purpose of proving that a fall of prices is identical with a fall of interest. Both things may, indeed, exist side by side. But if they do, it will be an expression of the opposite directions, in which the movement of industrial capital and of loan capital takes place. It will not be an expression of their identity.

Comment on sentence No. 3). Why money interest should be low, when commodities exist in abundance, is hard to understand, even after the foregoing remarks. If commodities are cheap, then I need, say, only 1,000 pounds sterling instead of 2,000 pounds sterling for a definite quantity which I may want to buy. But perhaps I might invest 2,000 pounds sterling nevertheless, and thus buy twice the quantity which I could have bought formerly. In this way I expand my business by advancing the same capital, which I may have to borrow. I buy 2,000 pounds sterling's worth of commodities, the same as before. My demand on the money market therefore remains the same, even though my demand on the commodity-market rises with the fall of the prices of commodities. But if this demand for commodities should decrease, that is, if production should not expand

with the fall of the prices of commodities, a thing contrary to all laws of the “Economist,” then the demand for loanable money-capital would be decreasing, although the profit would be increasing. But this increasing profit would create a demand for loan capital. For the rest, the low stand of the prices of commodities may be due to three causes. First, to a lack of demand. In that case the rate of interest is low, because production is paralyzed, not because commodities are cheap, since this cheapness is but an expression of that paralysis. In the second place, it may be due to a supply which is excessive compared to the demand. This may be the result of an overcrowding of markets, etc., which may lead to a crisis, and may go hand in hand with a high rate of interest during a crisis; or it may be the result of a fall in the value of commodities, so that the same demand may be satisfied at lower prices. Why should the rate of interest fall in the last case? Because the profits increase? If this should be due to the fact that less money-capital is required for the purpose of obtaining the same productive or commodity-capital, it would merely prove that profit and interest stand in an inverse proportion to one another. Certainly this general statement of the “Economist” is wrong. Low money prices of commodities and a low rate of interest do not necessarily go together. Otherwise the rate of interest would be lowest in the poorest countries, in which the money prices of commodities are lowest, and highest in the richest countries, in which the money prices of products of agriculture are highest. In a general way the “Economist” admits: If the value of money falls, it exerts no influence on the rate of interest. 100 pounds sterling bring 105 pounds sterling the same as ever. If the 100 pounds sterling are worth less, so are the 105 pounds sterling or the 5 pounds interest. This relation is not affected by the appreciation or depreciation of the original sum. Considered as a value, a definite quantity of commodities is equal to a definite sum of money. If this value rises, it is equal to a larger sum of money; the reverse takes place when it falls. If the value is 2,000, then 5% of it is 100; if it is 1,000, then 5% of it is 50. This does not alter anything in the rate of interest. The rational part of this matter is merely that a greater pecuniary accommodation is required, when it takes 2,000 pounds sterling to buy the same quantity of commodities, which may be bought for 1,000 pounds sterling at some other time. But this shows at this point merely that profit and interest are inversely proportionate to one another. For profit rises with the cheapness of the elements of constant and variable capital, whereas

interest falls. But the reverse may also take place, and does often take place. For instance, cotton may be cheap, because no demand exists for yarn and fabrics; and cotton may be relatively dear, because a large profit in the cotton industry creates a great demand for it. On the other hand the profits of the industrials may be high, just because the price of cotton is low. That list of Hubbard's proves that the rate of interest and the prices of commodities pass through mutually independent movements, whereas the movements of the rate of interest adapt themselves closely to those of the metal reserve and the rates of exchange.

Says the "Economist": "If, therefore, commodities are superabundant, then the money interest must be low." It is just the reverse which takes place during crises; the commodities are superabundant, not convertible into money, and therefore the rate of interest is high; in another phase of the cycle the demand for commodities is large, hence returns are easy, while prices of commodities are rising at the same time, and the rate of interest is low on account of the easy returns. "If they [the commodities] are scarce, it must be high." Once more the opposite is true in times of depression after a crisis. Commodities are scarce, absolutely speaking, not merely with reference to the demand; and the rate of interest is low.

Comment on sentence No. 4). It is pretty evident that an owner of commodities, provided he can sell them at all, will get rid of them at a lower price when the market is overcrowded than he will when there is a prospect of a rapid exhaustion of the existing supply. But why the rate of interest should fall on that account is not so clear.

If the market is overcrowded with imported commodities, the rate of interest may rise as a result of an increased demand for loan capital on the part of their owners, who may wish to escape the necessity of throwing their commodities on the market. On the other hand, the rate of interest may fall, because the fluidity of commercial credit may keep the demand for bank credit relatively low.

The "Economist" mentions the rapid effect on the rates of exchange in 1847, as a consequence of the raising of the rate of interest and other circumstances exerting a pressure on the money market. But it should not

be forgotten, that the gold continued to be drained off until the end of April, in spite of the turn in the rates of exchange; a change did not take place in this until the beginning of May.

On January 1, 1847, the metal reserve of the Bank was 15,066,691 pounds sterling; the rate of interest $3\frac{1}{2}\%$; rates of exchange for three months on Paris 25.75; on Hamburg 13.10; on Amsterdam $12.3\frac{1}{4}$. On March 5th the metal reserve had dwindled to 11,595,535 pounds sterling; the discount had risen to 4%; the rate of exchange fell to $25.67\frac{1}{2}$ for Paris; $13.9\frac{1}{4}$ for Hamburg; $12.2\frac{1}{2}$ for Amsterdam. The drain of gold continued. See the following table:

Date	1847	Precious Metal Reserve of the Bank of England	Money Market	Highest Three Monthly Rates	Paris	Hamburg	Amsterdam
March 20	11,231,630	Bk. Dc. 4%	$25.67\frac{1}{2}$	$13.9\frac{3}{4}$	$12.2\frac{1}{2}$	April 310,246,630	Bk. Dc. 5%
March 25	8,013,101	$12.3\frac{1}{2}$	April 109,867,053	Money very scarce	25.90	13.10	$1\frac{1}{3}$
April 17	9,329,941	Bk.Dc. 5.5%	$26.02\frac{1}{2}$	$13.10\frac{3}{4}$	$12.5\frac{1}{2}$	April 249,213,890	Pressure
May 26	0513,131	2.6	May 19,337,716	Increasing			
May 26	1513,12	$3\frac{1}{4}$	$12.6\frac{1}{2}$	May 89,588,759	Highest		
May 26	27	$1\frac{1}{2}$	$13.15\frac{1}{2}$	$12.7\frac{3}{4}$			

In 1847 the total exports of precious metals from England amounted to 8,602,597 pounds sterling.

Of this amount the United States received...3,226,411 pounds sterling
 France... 2,479,892 pounds sterling
 Hansa Towns...958,781 pounds sterling
 Holland...247,743 pounds sterling

In spite of the change in the rates at the end of March the drain of gold continued for another full month, probably to the United States.

“We see here” [says the “Economist,” 1847,], “how rapidly and strikingly the raising of the rate of interest exerted its effect, together with the subsequent money panic, in correcting an unfavorable rate of exchange and turning the tide of gold, so that it flowed once more into England. This effect was produced quite independently of the balance of payment. A higher rate of interest produced a lower price of securities, of English as well as foreign ones, and caused large purchases of them for foreign

accounts. This increased the sum of the bills of exchange drawn by way of England, while on the other hand, at the high rate of interest, the difficulty of obtaining money was so great, that the demand for these bills of exchange fell, while their sum rose. It was for the same reason that orders for foreign goods were annulled and the investment of English capital in foreign securities realised and the money taken to England for investment. For instance, we read in the "Rio de Janeiro Prices Current" of May 10: "The rate of exchange" [on England] "has experienced a new setback, caused mainly by a pressure on the market for remittances for the realisations on considerable purchases of [Brazilian] government bonds for English account." English capital, which had been invested in foreign countries in various securities, when the rate of interest was very low here, was thus taken back when the rate of interest had risen.

England's Balance of Trade.

India alone has to pay 5 millions in tribute for "good government," interest and dividends of British capital, etc., not counting the sums sent home annually by officials as savings of their salaries, or by English merchants as a part of their profit in order to be invested in England. Every British colony has to make large remittances continually for the same reason. Most of the banks in Australia, West India, Canada, have been founded with English capital, and the dividends are payable in England. In the same way England owns many foreign securities, European, North and South American, on which it draws interest. In addition to this it is interested in foreign railroads, canals, mines, etc., with the corresponding dividends. Remittance on all these items is made almost exclusively in products, in excess of the amount of the English exports. What goes to foreign countries from England to owners of English securities and to be consumed by Englishmen abroad, is a vanishing quantity in comparison.

The question, so far as it concerns the balance of trade and the rates of exchange, is "at every given moment a question of time. As a rule...England gives large credits on its exports, while its imports are paid in cash. In certain moments this difference of habit has considerable influence on the rates of exchange. At a time when our exports increase very considerably, as in 1850, there must take place a continual expansion in the investment of British capital...in this way remittances of 1850 may be made against goods

exported in 1849. But if the exports of 1850 exceed those of 1849 by more than 9 millions, the practical effect must be that more money is sent abroad, to this amount, than returned in the same year. And in this way an effect is produced on the rates of exchange and the rate of interest. But as soon as business is depressed by a crisis, and our exports are greatly reduced, the remittances due for large exports of former years considerably exceed the value of our imports; consequently the rates turn in our favor, capital rapidly accumulates in the home country, and the rate of interest falls.” (Economist, January 11, 1851.)

The foreign rates of exchange may be altered:

In consequence of a momentary balance of payment, no matter to what cause this may be due, whether it be a purely mercantile one, or the investment of capital abroad, or government expenditures, wars, etc., so far as cash payments are made to foreign countries.

In consequence of a depreciation of money in a certain country, whether it be metal or paper money. This is purely nominal. If one pound sterling should represent only half as much money as formerly, it would naturally be counted as 12.5 francs instead of 25 francs.

When it is a question of the rate of exchange between countries, one of which uses silver, the other gold as “money,” the rate of exchange depends upon the relative fluctuations of value of these two metals, since these fluctuations necessarily alter the parity between them. An illustration of this were the rates of exchange in 1850; they were against England, although its export rose enormously. But nevertheless no drain of gold took place. This was the result of a momentary rise in the value of silver as against that of gold. (See Economist, November 30, 1857.)

The parity of the rate of exchange is for one pound sterling: on Paris 25.20 francs; Hamburg 13 marks banko 10.5 shillings;¹¹³ Amsterdam 11 florins 97 centimes. In proportion as the rate of exchange on Paris exceeds 25.20 francs, it becomes more favorable to the English debtor of France, or the buyer of French commodities. In either case he needs less pounds sterling in order to accomplish his purpose. — In more remote countries, where precious metals are not easily obtained, when bills of exchange are scarce and insufficient for the remittances to be made to England, the

natural effect is a raising of the prices of such products as are generally shipped to England, a greater demand arising for them, in order to send them to England in place of bills of exchange; this is often the case in India.

An unfavorable rate of exchange, or even a drain of gold, may take place, when there is a great abundance of gold in England, a low rate of interest, and a high price of securities.

In the course of 1848 England received large quantities of silver from India, since good bills of exchange were rare and mediocre ones were not easily accepted, in consequence of the crisis of 1847 and the great lack of credit in the Indian business. All this silver, when hardly arrived, quickly found its way to the continent, where the revolution caused a formation of hoards at all points. The same silver largely made the trip back to India in 1850, since the stand of the rates of exchange made this profitable.

The monetary system is essentially Catholic, the credit system essentially Protestant. "The Scotch hate gold." In the form of paper the monetary existence of commodities has only a social life. It is Faith that makes blessed. Faith in money-value as the imminent spirit of commodities, faith in the prevailing mode of production and its predestined order, faith in the individual agents of production as mere personifications of selfexpanding capital. But the credit system does not emancipate itself from the basis of the monetary system any more than Protestantism emancipates itself from the foundations of Catholicism.

CHAPTER XXXVI. PRECAPITALIST CONDITIONS.

INTEREST bearing capital, or usurer's capital, as we may call it in its ancient form, belongs like its twin brother, commercial capital, to the antediluvian forms of capital, which long precede the capitalist mode of production and are found in the most diverse economic formations of society.

The existence of usurer's capital requires merely that at least a portion of the products should be converted into commodities, and that money with its various functions should have developed along with the trade in commodities.

The development of capital attaches itself to that of merchant's capital, more particularly to financial capital. In ancient Rome, starting from the last stages of the republic, when manufacture stood far below its ancient average development, merchants' capital, financial capital, and usurers' capital had reached their highest point within that ancient form.

We have seen that hoarding necessarily appears with money. But the professional hoarder does not become important until he becomes transformed into a usurer.

The merchant borrows money in order to make a profit with it, in order to use it as capital, that is, to spend it as such. Hence the money lender stands in the same relation to him in former stages of society as he does to the modern capitalist. This specific relation was felt also by the Catholic universities. "The universities of Alcala, of Salamanca, of Ingolstadt, of Freiburg in the Breisgau, Mayence, Cologne, Treves, one after another recognized the legality of interest for commercial loans. The first five of these approbations were deposited in the archives of the Consulate of the city of Lyons and published in the appendix of the *Traité de l'usure et des intérêts*, at Lyons, by Bruyset-Ponthus." (M. Augier, *Le Crédit Public*, etc., Paris, 1842, .)

In all forms, in which slave economy (not the patriarchal kind, but that of later Grecian and Roman times) serves as a means of amassing wealth, where money is a means of appropriating the labor of others by purchase of slaves, land, etc., there money becomes useful as capital, brings interest, for the reason that it may be so invested.

However, the most characteristic forms, in which usurers' capital exists in times antedating capitalist production, are two. I say purposely characteristic forms. The same forms repeat themselves on the basis of capitalist production, but as mere subordinate forms. They are then no longer the forms which determine the character of interest-bearing capital. These two forms are: First, usury by lending money to extravagant persons of the higher classes, particularly to land owners; secondly, usury by lending money to the small producer who is in possession of his own means of employment, which includes the artisan, but more particularly the peasant, since under precapitalist conditions, so far as they permit of independent individual producers, the peasant class must form the overwhelming majority.

Both the ruin of rich land owners by usury and the spoilage of the small producers leads to the formation and concentration of large money-capitals. But to what extent this process does away with the old mode of production, as happened in modern Europe, and whether it places in its stead the capitalist mode of production, depends entirely upon the stage of historical development and the circumstances surrounding it.

Usurers' capital as the characteristic form of interest-bearing capital corresponds to the predominance of small scale production, of selfemploying peasants and small craft masters. When the laborer is confronted by the means of employment and by the product of labor in the shape of capital, as he is under the capitalist mode of production, he has no occasion to borrow any money as a producer. When he does any borrowing of money, he does it to secure personal necessities, for instance, at the pawnshop. But wherever the laborer is the owner, whether actual or nominal, of his means of employment and of his product, he is confronted as a producer by the capital of the money lender, which stands in his way as

a usurer's capital. Newman expresses the matter weakly, when he says that the banker is respected while the usurer is hated and despised, because the banker lends to the rich, whereas the usurer lends to the poor. (J. W. Newman, *Lectures on Political Economy*, London, 1851, .) He overlooks the fact that the difference of two modes of social production and of the corresponding social orders intervenes here and that the matter is not exhausted by the distinction between rich and poor. On the contrary, the usury which sucks the life out of the small producer goes hand in hand with the usury which sucks the rich owner of large estates dry. As soon as the usury of the Roman patricians had completely ruined the Roman plebeians, the small peasants, this form of exploitation had an end and slave economy undisguised took the place of small peasant economy.

Under the form of interest the whole of the surplus over the necessary means of subsistence (the amount of what becomes wages later on) of the producers may here be devoured by usury (this assumes later the form of profit and ground rent), and hence it is very absurd to compare the level of this interest, which assimilates all the surplus-value with the exception of the share claimed by the state, with the level of the modern rate of interest, which gives to the interest normally no more than a part of the surplus-value. Such a comparison forgets that the wage worker gives to the capitalist, who employs him, profit, interest and ground rent, that is, the whole surplus-value produced by him. Carey makes this absurd comparison in order to show, how advantageous the development of capital and the fall in the rate of interest, that goes with it, is for the laborer. When it is said that the usurer, not content with squeezing the surplus-labor out of his victim, gradually acquires possession of the means of employment, house and land, of this victim and is thus continually engaged in expropriating him, it is forgotten that this complete expropriation of the laborer from his means of employment is not a result which the capitalist mode of production seeks to accomplish, but rather the established condition from which it starts out. The wage slave is barred from becoming a creditor's slave just as the real slave was, at least in his capacity as a producer. The wage slave may eventually become a creditor's slave in his capacity as a consumer. Usurer's capital in this form, in which it appropriates indeed all surplus-labor of the direct producers, does not alter the mode of production. The ownership, or at least the possession of the means of employment by the producers, and

small scale production corresponding to this, are its essential prerequisites. Here capital does not subordinate labor to itself directly, and does not confront the laborer as industrial capital, while usurer's capital merely impoverishes this mode of production, paralyzes the productive forces instead of developing them, and at the same time perpetuates these miserable conditions, in which the social productivity of labor is not developed at the expense of labor itself, as it is under the capitalist mode of production.

On the one hand, usury thus exerts an undermining and destructive influence on ancient and feudal wealth and ancient and feudal property. On the other hand it undermines and ruins small peasants' and small burghers' production, in short all forms, in which the producer still appears as the owner of his conditions of production. Under the developed capitalist mode of production, the laborer is not the owner of his means of employment, of the field which he cultivates, of the raw materials which he works up, etc. But under this system the separation of the producer from the means of employment is the expression of an actual revolution of the mode of production itself. The individual laborers are brought together in large workshops for the purpose of a division of labor, which dovetails one man's activity into another's. The tool becomes a machine. The mode of production no longer permits this dislocation of the means of production, which goes with small property, nor does it permit the isolation of the laborer himself. Under the capitalist mode of production, usury can no longer separate the producer from his means of production, for the simple reason that they have already been separated.

Usury centralises money wealth, where the means of production are disjointed. It does not alter the mode of production, but attaches itself to it as a parasite and makes it miserable. It sucks its blood, kills its nerve, and compels reproduction to proceed under even more disheartening conditions. Hence the popular hatred against usurers, which was most pronounced in the ancient world, where the ownership of the means of production by the producer himself was at the same time the basis of the political conditions, of the independence of the citizen. To the extent that slavery prevails, or to the extent that the surplus product is consumed by the feudal lord and his retinue, while either the slave owner or the feudal lord fall into the clutches

of the usurer, the mode of production remains the same. Only, it becomes harder on the laborer. The indebted slave holder or feudal lord becomes more oppressive, because he is himself more oppressed. Or he makes finally room for the usurer, who becomes a landed proprietor or a slave holder himself, like the knights in ancient Rome. Into the place of the old exploiters, whose exploitation was more or less patriarchal, because it was largely a means of political power, steps a hard, money-mad parvenue, But the mode of production itself is not altered thereby.

Usury works revolutionary effects in all precapitalist modes of production only so far as it destroys and dissolves those forms of property, which form the solid basis of the political organisation, and which must be continually reproduced in order that the political organisation may endure. Under the Asiatic forms usury may last for a long time, without producing anything else but economic disintegration and political rottenness. Not until the other prerequisites of capitalist production are present, does usury become a means of assisting in the formation of the new mode of production, by ruining the feudal lord and small scale production on the one hand, and centralising the means of production into capital on the other.

In the Middle Ages no country had any general rate of interest. The Church forbade all lending at interest from the outset. Laws and courts protected loans but very little. Interest was so much higher in individual cases. The limited circulation of money, the necessity of making most payments in cash, compelled people to borrow money, so much more the less the business of exchanging money was developed. There was a great deal of difference, both in the rates of interest and the conceptions of usury. In the time of Charlemagne it was considered usury to charge 100%. In Lindau on Lake Boden some resident burghers took 216 2/3% in 1348. In Zurich the City Council decreed that 43 1/3% should be the legal rate of interest. In Italy 40% had to be paid sometimes, although the ordinary rate did not exceed 20% from the 12th to the 14th century. Verona ordered that 12½% should be the legal rate. Emperor Frederick II. fixed the rate at 10%, but only for Jews. He did not care to speak for the Christians. In the Rhine provinces 10% was the rule as early as the 13th century. (Hüllmann, *Geschichte des Städtewesens*, II, p-57.)

Usurer's capital uses a capital's method of exploitation without its mode of production. This state of affairs repeats itself also inside of bourgeois economy, in backward lines of industry or in those lines, which resist the transition to the modern mode of production. For instance, if we wish to compare the English rate of interest with the Indian, we should not take the rate of interest of the Bank of England, but rather that, say, of the lenders of small machinery to small producers in domestic industry.

Usury as an enemy of consuming wealth is historically important inasmuch as it is itself a process generating capital. Usurer's capital and merchant's wealth promote the formation of moneyed wealth independent of landed property. The less products assume the character of commodities, and the less exchange-value seizes the whole breadth and depth of production, the more does money appear as real wealth, that, is, as wealth in general compared to its limited existence in use-values. This is the basis of hoarding. Aside from money as world money and a hoard, it assumes the absolute form of commodities particularly as a means of payment. And it is especially its function as a means of payment, which develops interest and with it money-capital. What squandering and corrupting wealth wants is money as such, money as a means of buying everything (also as a means of paying debts). The small producer needs money above all to make payments. (The conversion of tithes in kind and service in kind to landlords and to the state into money rent and money taxes plays a great role in this.) In either case money is used as money proper. On the other hand hoarding becomes real only in this way, and thus fulfills the dreams of the usurer. What the owner of a hoard demands is not capital, but money as such; but by means of interest he converts his hoard of money into capital for himself, that is, into a means of grabbing surplus-labor in part or entirely, and with it securing a hold on a part of the requirements of production itself, even though this may remain separate from him as a nominal property of others. Usury lives apparently in the pores of production in the same way as the gods live in the spaces between worlds according to Epicurus. Money is obtainable so much harder, the less products assume the general form of commodities. Hence the usurer acknowledges no other barrier but the capacity or resistive power of those who need money. In small peasants' and small burghers' production money serves as a means of purchase mainly, whenever the laborer (who is still to a predominant extent the

owner of his means of production under these modes of production) loses his means of employment by accident or by extraordinary upheavals, or at least does not become able to recover them in the ordinary course of reproduction. Means of subsistence and raw materials constitute the essential part of these requirements of production. If these become dearer, it may be impossible to reproduce them out of the returns for the product, just as mere crop failures may prevent the peasant from reproducing his seed grain in its natural form. The same wars, by which the Roman patricians ruined the plebeians, by compelling them to serve as soldiers and thus preventing them from reproducing the requirements of their productive activity and making paupers of them (and pauperization, depletion or loss of the prerequisites of reproduction is here the predominant form), filled the sheds and cellars of the patricians with looted copper, the money of that time. Instead of giving to the plebeians directly the necessary commodities, grain, horses, cattle, they loaned to them this copper, for which they had no use themselves, and availed themselves of this condition for the purpose of enforcing enormous interest by usury, thereby turning the plebeians into their debtor slaves. Under the reign of Charlemagne the Frankish peasants were likewise ruined by wars, so that nothing remained to them but to become serfs instead of debtors. In the Roman empire it happened frequently that famines caused the sale of children, or the voluntary sale of free men by themselves, into slavery to the rich. So much for general turning points. In individual cases the maintenance or loss of the requirements of production on the part of the small producers depend on a thousand accidents, and everyone of such accidents or losses signifies impoverishment and becomes an opening, into which the parasite of usury may enter. The mere death of a cow may render the small producer unable to renew his reproduction on the former scale. Then he falls into the clutches of the usurer, and once he is in the usurer's power he never extricates himself.

The typical great and peculiar domain of the usurer, however, is the function of money as a means of payment. Every payment of money, ground rent, tribute, tax, etc., which becomes due at a certain date, carries with it the necessity of securing money for such a purpose. Hence usury attaches itself from the days of the ancient Romans to those of modern times to the tax renters, the *fermiers généraux*, the *receveurs généraux*.

Furthermore, commerce and the extension of commodity-production carry with them the separation of purchase and payment by an interval of time. The money has to be on the spot at a definite date. In what manner this may lead to circumstances, in which the money-capitalist and usurer may merge into one even nowadays, is shown by the modern money panics. This same usury, however, becomes one of the principal means of further developing the necessity of using money as a means of payment, by getting the producer ever more deeply into debt and destroying his usual means of payment in such a way that the burden of interest makes even his normal reproduction impossible. In that case usury sprouts up out of money as a means of payment and extends this function of money into its own peculiar domain.

The development of the credit system takes place as a reaction against usury. But this should not be misunderstood, nor interpreted in the manner of the ancient writers, the church fathers, Luther, or the older socialists. It signifies no more and no less than the subordination of interest-bearing capital to the conditions and requirements of the capitalist mode of production.

On the whole, interest-bearing capital under the modern credit-system is adapted to the conditions of the capitalist mode of production. Usury as such does not merely perpetuate itself, but is even freed by nations with a developed capitalist production from those fetters, which were imposed upon it by the old legislation. Interest-bearing capital retains the form of usurer's capital in its transactions with such persons or classes, or those in such circumstances, as do not borrow in the sense corresponding to the capitalist mode of production, or in which borrowing cannot take place in that sense. This applies to borrowing from individual want at the pawnshop; to lending money for the purpose of squandering on the part of wealthy spendthrifts; or to borrowing money on the part of producers who are not capitalist producers, such as small farmers, craftsmen, etc., who are still the owners of their own requirements of production; finally to borrowing on the part of capitalist producers, who still operate on such a small scale, that they approach those self-employing producers.

What distinguishes the interest-bearing capital, so far as it is an essential element of the capitalist mode of production, from usurer's capital is in no way the nature or the character of this capital itself. It is merely the altered conditions, under which it operates, and consequently the totally changed character of the borrower, who transacts business with the money lender. Even in cases where a man without wealth receives credit in his capacity as an industrial or merchant, it is done for the confident expectation, that he will perform the function of a capitalist and appropriate some unpaid labor with the borrowed capital. He receives credit in his capacity as a potential capitalist. This circumstance, that a man without wealth, but with energy, solidity, ability and business sense may become a capitalist in this way, is very much admired by the apologists of the capitalist system, and the commercial value of each individual is pretty accurately estimated under the capitalist mode of production. Although this circumstance continually brings an unwelcome number of new soldiers of fortune into the field and into competition with the already existing individual capitalists, it also secures the supremacy of capital itself, expands its basis, and enables it to recruit ever new forces for itself out of the lower layers of society. In a similar way the circumstance, that the Catholic Church in the Middle Ages formed its hierarchy out of the best brains of people without regard to estate, birth, or wealth, was one of the principal means of fortifying priest rule and suppressing the laity. The more a ruling class is able to assimilate the most prominent men of a ruled class, the more solid and dangerous is its rule.

Instead of the anathema against interest-bearing capital in general, it is on the contrary its explicit recognition, from which the initiators of the modern credit system take their start.

We are not speaking here of such reactions against usury, as tried to protect the poor against it, like the Monts-de-piété (1350 in Sarlins of the Franche-Comté, later in Perugia and Savona of Italy, 1400 and 1479). These are remarkable mainly because they show the irony of history, which turns pious wishes into their very opposite as soon as they are realised. According to a moderate estimate the English working class pays 100% to the pawnshops, those modern successors of the Monts-de-piété.¹¹⁴ Neither are we speaking of the credit phantasies of a man like Dr. Hugh Chamberleyne

or John Briscoe, who attempted during the last decade of the 17th century to emancipate the English aristocracy from usury by means of a country bank with paper money based on real estate.¹¹⁵

The credit associations, which were established in the 12th and 14th centuries in Venice and Genoa, arose from the need of marine commerce and wholesale trade connected with it to emancipate themselves from the domination of ancient usury and from the monopolists of the money business. The fact that the bona fide banks, which were founded in those city-republics, assumed at the same time the shape of institutions for public credit, from which the state received loans on future tax revenues, is explained by the circumstance that the merchants forming such associations were the prominent men of those states and as much interested in emancipating their state as themselves from the exactions of usurers,¹¹⁶ and at the same time getting a better and more secure control of the states themselves. Hence, when the Bank of England was being planned, the Tories raised the objection: "Banks are republican institutions. Flourishing banks exist in Venice, Genoa, Amsterdam, and Hamburg. But who ever heard of a Bank of France or Spain?"

The Bank of Amsterdam, in 1609, did not mark an epoch in the development of the modern credit system any more than that of Hamburg in 1619. It was purely a bank for deposits. The checks issued by the bank were indeed merely receipts for the deposited, coined and uncoined, precious metal, and circulated only with the endorsement of those who received them. But in Holland commercial credit and dealing in money had developed together with commerce and manufacture, and the interest-bearing capital had been subordinated to industrial and commercial capital by the course of development itself. This showed itself even in the lowness of the rate of interest. And Holland was considered in the 17th century as the model country of economic development, as England is now. The monopoly of old-style usury, based on poverty, had been overthrown in that country of its own weight.

During the entire 18th century Holland is pointed out as an example and the cry raised for a compulsory lowering of the rate of interest (and legislation acted on this hint), in order to subordinate the interest-bearing

capital to the commercial and industrial capital, instead of maintaining the reverse condition. The main spokesman of this movement is Sir Josiah Child, the father of normal English bankedom. He declaims against the monopoly of the usurers in much the same way that the wholesale clothing manufacturer Moses & Son do when posing as the leaders of the fight against the monopoly of the private tailors. This Josiah Child is at the same time the father of English stock jobbing. Thus he, the autocrat of the East India Company, defends its monopoly in the name of free trade. About Thomas Manley ("Interest of Money Mistaken") he says: "As the champion of the timid and trembling band of usurers he erects his batteries at that point, which I have declared to be the weakest...he denies point blank that the low rate of interest is the cause of wealth and vows that it is merely its effect." *Traité sur le Commerce, etc.*, 1669, translated in Amsterdam and Berlin, 1754.) "If it is commerce that enriches a country, and if a lowering of interest increases commerce, then a lowering of interest or a restriction of usury is doubtless a fruitful primary cause of the wealth of a nation. It is not at all absurd to say that the same thing may be simultaneously a cause under certain circumstances, and an effect under others." (L. c., .) "The egg is the cause of the hen, and the hen is the cause of the egg. The lowering of interest may cause an increase of wealth, and the increase of wealth may cause a still greater reduction of interest." (L. c., .) "I am the defender of industry and my opponent defends laziness and sloth." (P. 179.)

This violent fight against usury, this demand for the subordination of the interest-bearing under the industrial capital, is but the herald of the organic creations, that establish these prerequisites of capitalist production in the modern banking system, which on the one hand robs usurer's capital of its monopoly by concentrating all fallow money reserves and throwing them on the money-market, and on the other hand limits the monopoly of the precious metals themselves by creating credit-money.

The same opposition to usury, the demand for emancipation of commerce, industry and of the state from usury, which we observe here in the case of Child, will be found in all writings on banking during the last third of the 17th and the beginning of the 18th centuries. With them go also colossal illusions about the miraculous effects of credit, the abolition of the monopoly of precious metals, their displacement by paper, etc. The

Scotchman William Patterson, the founder of the Bank of England and the Bank of Scotland, is by all odds Law the First.

Against the Bank of England all goldsmiths and pawn-brokers raised a howl of rage. (Macaulay, History of England, IV., .) During the first ten years the Bank had to struggle with great difficulties; great enmity from without; its notes were only accepted far below their nominal value...the goldsmiths (in whose hands the trade with precious metals served as a basis of a primitive banking business) intrigued considerably against the Bank, because their business was reduced by it, their discount lowered, and their business with the government had fallen into the hands of this antagonist. (J. Francis, l. c., .)

Even before the establishment of the Bank of England a plan for a national bank of credit was suggested in 1683, which had for its purpose, among others, “that business men, when they possess a considerable quantity of goods, may deposit their goods with the assistance of this bank and take up a credit on their tied-up supplies, employ their hands, and increase their business, until they find a good market, instead of selling at a loss.” After many difficulties this Bank of Credit was erected in Devonshire House in Bishopsgate Street. It made loans to industrials and merchants on security of deposited goods to the amount of three quarters of their value, in bills of exchange. In order to make these bills of exchange marketable, a number of people in each branch of business were organised into a society, from whom every possessor of such bills should be able to get goods with the same facility as though he were to offer them cash payment. This bank did not do a flourishing business. Its machinery was too complicated, the risk too great in case of a depreciation of commodities.

If we go by the real content of those writings, which accompany and promote theoretically the formation of the modern credit system in England, we shall not find anything in them but the demand for a subordination of interest-bearing capital, and of loanable means of production in general, under the capitalist mode of production as one of its prerequisites. On the other hand, if we cling to the mere phraseology, we shall be frequently surprised by their agreement, down to the very expressions, with the banking and credit illusions of the Saint-Simonists.

Just as the cultivateur in the writings of the physiocrats does not signify the actual tiller of the soil, but the great land owner, so the travailleur with Saint-Simon, and continuing on through his disciples, does not signify the laborer, but the industrial and commercial capitalist. “A travailleur (worker) needs help, backers, laborers; he looks for such as are intelligent, able, devoted; he puts them to work, and their labor is productive.” (*Religion saint-simonienne, Économie politique et Politique*. Paris, 1831, .)

In fact, one should not forget that only in his last work, *Le Nouveau Christianisme*, does Saint-Simon speak directly for the working class and declare their emancipation to be the end of his efforts. All his former writings are, indeed, mere glorifications of modern bourgeois society against feudal society, or of industrials and bankers against marshals and jurist law-makers of the Napoleonic era. What a difference compared with the contemporaneous writings of Owen!117

Among his followers, like wise, the industrial capitalist remains the travailleur par excellence, as the above quoted passage indicates. After reading their writings critically, one will not be surprised, that the realization of their dreams of banks and the upshot of their critique materialised in the *Crédit mobilier* founded by the Ex-Saint-Simonist Emile Pereire. This form of credit could become prevalent only in a country like France, where neither the credit system nor great industries had become developed to a modern scale.

In the following passage of the “*Doctrine de Saint-Simon, Exposition, Première année, 1828-29*” (Third edition, Paris, 1831), the germ of the *Crédit mobilier* is already contained. It is easy to understand, that the banker can lend money more cheaply than the capitalist and the private usurer. The bankers are, therefore, “able to procure tools to the industrials far more cheaply, that is, at a lower interest than the real estate owners and capitalists can, who may be more easily mistaken in their choice of borrowers.” (P. 202.) But the authors themselves add in a footnote: “The advantage that would follow from an intervention of bankers between the idle and the travailleurs is often balanced, or even annulled, by the opportunities offered by our disorganized society to Egoism, which may manifest itself in various

forms of fraud and charlatanry. The bankers often come between the idle and the travailleurs for the purpose of exploiting both of them to the injury of society.” Travailleur means here industrial capitalist. For the rest it is a mistake to consider the means at the command of banks merely as means of idle people. In the first place the banks hold that portion of capital, which industrials and merchants own temporarily in the form of unemployed money, as a money reserve or as capital to be invested. It is idle capital, but not capital of idle people. In the second place the banks hold that portion of the revenues and savings of all kinds which is to be temporarily or permanently accumulated. Both things are essential for the character of the banking system.

But it should never be forgotten, that money, in the first place, in the form of precious metals, remains the basis from which the credit system naturally can never detach itself. In the second place, it must be kept in mind that the credit system has for its premise the monopoly of the social means of production in the hands of private people (in the form of capital and landed property), that it is itself on the one hand an immanent form of the capitalist mode of production, and on the other hand one of the impelling forces of the development of this mode of production to its highest and ultimate form.

The banking system, so far as its formal organisation and centralisation is concerned, is the most artificial and most developed product turned out by the capitalist mode of production, a fact already expressed in 1697 in “Some Thoughts of the Interests of England.” This accounts for the immense power of such an institution as the Bank of England over commerce and industry, although their actual movements remain quite outside of its sphere and it is passive toward them. It presents indeed the form of universal bookkeeping and of a distribution of products on a social scale, but only the form. We have seen that the average profit of the individual capitalist, or of every individual capital, is determined, not by the surplus-labor appropriated at first hand by each capital, but by the total quantity of surplus-labor appropriated by the total capital, whereof each individual capital receives a dividend as an aliquot part of the total capital. This social character of capital is promoted and fully realised by the complete development of the credit and banking system. On the other hand

this goes still farther. It places at the disposal of the industrial and commercial capitalists all the available, or even potential, capital of society, so far as it has not been actively invested, so that neither the lender nor the user of such capital are its real owners or producers. This does away with the private character of capital and implies in itself, to that extent, the abolition of capital. By means of the banking system the distribution of capital as a special business, as a social function, is taken out of the hands of the private capitalists and usurers. But at the same time banking and credit thus become the most effective means of driving capitalist production beyond its own boundaries, and one of the most potent instruments of crises and swindle.

The banking system shows, furthermore, by putting different forms of circulating credit in the place of money, that money is in reality nothing but a special expression of the social character of labor and its products, so that this character, as distinguished from the basis of individual production, must present itself in the last analysis as a thing, as a peculiar commodity by the side of the other commodities.

Finally, there is no doubt that the credit system will serve as a powerful lever during the transition from the capitalist mode of production to the production by means, of associated labor; but only as one element in connection with other great organic revolutions of the mode of production itself. On the other hand, the illusions concerning the miraculous power of the credit and banking system, as nursed by some socialists, arise from a complete lack of familiarity with the capitalist mode of production and the credit system as one of its forms. As soon as the means of production have ceased to be converted into capital (which includes also the abolition of private property in land), credit as such has no longer any meaning. This was understood also by the advocates of Saint-Simonism. But so long as the capitalist mode of production lasts, interest-bearing capital as one of its forms also continues and constitutes actually the basis of the credit system. Only that sensational writer, Proudhon, who wanted to perpetuate the production of commodities and yet abolish money¹¹⁸, was capable of dreaming of a *crédit gratuit*, this monster which was supposed to realise the pious wish of small capitalist production.

In the “Religion saint-simonienne, Économie et Politique,” we read on page 45: “Credit serves the purpose, in a society in which some own the instruments of industry without the ability or the will to employ them, and in which other industrious people have no instruments of labor, of transferring these instruments in the easiest manner possible from the hands of the former, their owners, to the hands of the others who know how to use them. Note that this definition regards credit as a result of the way in which property is constituted.” Therefore credit disappears with this constitution of property. We read, furthermore, on page 98, that the present banks “consider it their business to yield to that movement which is started by the transactions taking place outside of their domain, not to give them an impulse on their part; in other words, the banks perform the role of capitalists in their transactions with those travailleurs, to whom they loan money.” The idea that the banks themselves should take the lead and distinguish themselves “through the number and usefulness of the organised establishments and of the promoted works” contains the *Crédit mobilier* in embryo. In the same way Charles Pecqueur demands that the banks (or what the Saint-Simonists call a *Système général des banques*) “should rule production.” Pecqueur is essentially a Saint-Simonist, only much more radical. He desires that “the credit institute...should control the entire movement of national production.”— “Try to create a national credit institute, which shall advance means to propertyless talent and merit, without, however, knitting these borrowers by compulsion into a close solidarity in production and consumption, but on the contrary rather enabling them to determine their own exchanges and production. In this way you will accomplish only what the private banks accomplish even now, that is, anarchy, a disproportion between production and consumption, the sudden ruin of one, and the sudden enrichment of another; so that your institute will never get any farther than the point of producing a great deal of welfare for one, which amounts to a great deal of suffering endured by another...only that you will have given to the wage laborers assisted by you the means of competing among one another in the same way that their capitalist masters do now.” (Ch. Pecqueur, *Théorie Nouvelle d’ Économie Sociale et Politique*, Paris, 1842, .)

We have seen that merchants’ capital and interest-bearing capital are the most ancient forms of capital. In the nature of the case, interest-bearing

capital assumes in the popular conception the form of capital par excellence. In the case of merchants' capital, the activity of a middle man is performed, no matter whether it be rated as cheating, labor, or anything else. But in the case of interest-bearing capital the self-reproducing character of capital, the self-expansion of value, the production of surplus-value, surrounds itself with the qualities of the occult. This accounts for the fact that even a part of the political economists, particularly in countries in which industrial capital is not yet fully developed, as in France, cling to interest-bearing capital as the fundamental form of capital and regard, for instance, ground rent merely as a modified form of it, because the form of lending predominates also in it. In this way the internal articulation of the capitalist mode of production is completely misunderstood, and the fact is entirely overlooked that land, like capital, is loaned only to capitalists. Of course, natural means of production, such as machines, business buildings, etc., may also be loaned instead of money. But they always represent a certain sum of money, and the fact that not only interest, but also wear and tear has to be paid for them, is due to their use-value, the specific natural form of these elements of capital. The thing which decides in this case is whether they are loaned to the direct producers, which would imply the non-existence of the capitalist mode of production, at least in the sphere in which this takes place, or whether they are loaned to the industrial capitalists, which is the basic assumption under the capitalist mode of production. It is still more improper and meaningless to drag the lending of houses, etc., for individual consumption into this part of the discussion. That the working class is swindled to an enormous extent, in this way as well as in others, is an evident fact; but this is done also by the retail dealer, who sells them means of subsistence. It is a secondary exploitation, which runs parallel with the primary one taking place in the process of production itself. The distinction between selling and loaning is quite immaterial in this case and merely formal, and cannot appear as essential to any one, unless he be wholly unfamiliar with the actual condition of the problem.

Both usury and commerce exploit the various modes of production. They do not create it, but attack it from the outside. Usury tries to maintain it directly, in order to be able to exploit it ever anew, but it is conservative and makes it only more miserable. The less the elements of production enter the process of production as commodities and come out of it as commodities,

the more does their descent from money appear as a separate act. The more significant the role played by circulation in the social reproduction, the more does usury flourish.

That moneyed wealth develops as a special kind of wealth means with reference to usurer's capital that it collects all its claims in money. It develops so much more in any country, the more the mass of production limits itself to natural services, etc., that is, to use-values.

To that extent usury has a double effect. First, it frames up an independent moneyed wealth by the side of the merchant class. In the second place it appropriates to itself the prerequisites of labor, that is, it ruins the owners of the old requisites of production. Thus it becomes a powerful lever for the formation of the requirements of industrial capital.

Interest in the Middle Ages.

In the Middle Ages the population was purely agricultural. And there, as under feudal rule, commerce can be but small and consequently profit but slight. Hence the laws against usury were justified in the Middle Ages. Moreover, in an agricultural country one has rarely any occasion for borrowing money, except when reduced by poverty and misery....Henry VIII limits interest to 10%, Jacob I. to 8%, Charles II, to 6%, Anne to 5%....In those days the money-lenders, if not legally, were at least in fact monopolists, and therefore it was necessary to place them under restriction like other monopolists....In our times the rate of profit regulates the rate of interest; in those times the rate of interest regulated the rate of profit. If the money-lender loaded a heavy rate of interest on the merchant, then the merchant had to add a higher rate of profit to the price of his commodities. Consequently a large sum of money was taken out of the pockets of the buyers in order to put it into the pockets of the money-lenders. (Gilbart, History and Principles of Banking, p, 165.)

“I have been told that 10 gulden are now taken annually on every Leipsic fair, that is 30 on each hundred; some add the Neuenburg fair and make it 40 per hundred; whether that is so, I don't know. For shame, where the devil is that going to end?...Whoever has now 100 florins at Leipsic, takes 40 annually, which is the same as devouring one peasant or burgher each year.

If one has 1,000 florins, he takes 400 annually, which means devouring a knight or a rich noble per year. If one has 10,000 florins, he takes 4,000 per year, which means devouring a rich count each year. If one has 100,000 florins, as the great merchants must have, he takes 40,000 annually, which means devouring one great rich prince each year. If one has 1,000,000 florins, he takes 400,000 annually, which means devouring one great king each year. And he does not run any risks, either in his person or his wares, does not work, sits near his fireplace and roasts apples; so might a petty robber be sitting at home and devour a whole world in ten years.” (Bücher vom Kaufhandel und Wucher, 1524. Luther’s Works, Wittenberg, 1589, Part VI.)

“Fifteen years ago I wrote against usury, when it had spread so alarmingly, that I did not hope for any improvement. Since then it has become so proud, that it does not care to be classed as a vice, sin, or shame, but gets itself praised as a pure virtue and honor, just as though it were doing people a great favor and Christian service. What are we going to do now that shame has become honor and vice virtue? (Martin Luther, An die Pfarherrn wider den Wucher zu predigen. Wittenberg, 1540.)

Jews, Lombards, usurers and bloodsuckers were our first bankers, our original bank sharks, their character being such as to be called almost infamous....They were joined by the London goldsmiths. On the whole...our original bankers...were a very bad crowd, they were greedy usurers, stony-hearted vampires. (J. Hardcastle, Banks and Bankers. Second edition, London, 1843, pages 19 and 20.)

The example given by Venice (in the matter of establishing a bank) was quickly imitated; all sea towns, and in general all towns which had made a name for themselves by their independence and their commerce, founded their first banks. The return of their ships, which often took a long time, led inevitably to the custom of giving credit, which was further intensified by the discovery of America and the commerce with it. (This is one of the main points.) The freighting of ships made the taking of heavy loans necessary, a thing already occurring in ancient Athens and Greece. In 1380 the Hansa town of Bruges had an insurance company. (M. Augier, l. c., pages 202 and 203.)

To what extent the making of loans to land owners, and to wealth consumers in general, still prevailed in the last third of the 17th century, even in England, before the development of the modern credit system, may be seen in the works of Sir Dudley North, among others. He was not only one of the first English merchants, but also one of the most prominent theoretical economists of his time. And he says: The money loaned among our people at interest is not even to a tenth part given to business people for carrying on their affairs; it is loaned for the greater part for articles of luxury, and for the expenditures of people, who, although great real estate owners, nevertheless spend money faster than is made by their real estate; and since they hate to sell their estates, prefer to mortgage them. (Discourses upon Trade. London, 1691, pages 6 and 7.)

Poland in the 18th century: “Warsaw did a great business in exchange, which, however had for its principal basis and aim the usury of its bankers. In order to secure money, which they might lend to spendthrift nobles at 8% and more, they sought and obtained abroad an exchange credit in blank, that is, it had no commerce with commodities at all for a foundation, but the foreign endorser of the bill stood it patiently, so long as the returns from swindling with bills of exchange did not fail. However, they paid heavily for this by the bankruptcies of men like Tapper and other highly respected Warsaw bankers.” (J. G. Büsch, *Theoretisch-praktische Darstellung der Handlung*, etc., third edition, Hamburg, 1808, volume II, pages 232 and 233.)

Advantage of the Prohibition of Interest for the Church.

“The taking of interest had been forbidden by the church. But the sale of property for the purpose of getting out of a tight place had not been forbidden. It had not even been forbidden to transfer property for a certain period to the money lender as a security, until such time as the debtor should repay his loan, so that the money lender might have the use of the property as a reward for the absence of his money....The church itself and the various corporations and communes belonging to it derived much profit from this practice, particularly during the period of the crusades. This brought a very large portion of the national wealth into the possession of the so-called ‘dead hand,’ all the more so because the Jews were barred from

engaging in such usury, the possession of such fixed liens not being concealable....Without the ban on interest the churches and cloisters would never have become so rich.” (L. c., .)

PART VI. TRANSFORMATION OF SURPLUS PROFIT INTO GROUND-RENT.

CHAPTER XXXVII. PRELIMINARIES.

THE analysis of landed property in its various historical forms belongs outside of the limits of this work. We shall occupy ourselves with it in this place only to the extent that a portion of the surplus-value produced by the industrial capital falls into the hands of the land owner. We assume, then, that agriculture is dominated by the capitalist mode of production, just as manufacture is, in other words, that agriculture is carried on by capitalists, who differ primarily from the other capitalists only through the element, in which their capital and the wage-labor set in motion by this capital are invested. So far as we are concerned, the capitalist farmer produces wheat, etc., in the same way that the manufacturer produces yarn or machines. The assumption that the capitalist mode of production has seized agriculture implies that it rules all spheres of production and bourgeois society, so that its prerequisites, such as free competition among capitals, the possibility of transferring them from one sphere of production to another, a uniform level of the average rate of profit, etc., are fully matured. The form of landed property which we consider here is a specifically historical one, a form altered through the influence of capital and of the capitalist mode of production, and evolved either out of feudal land ownership, or out of small peasants' agriculture carried on for a living, in which the possession of land constitutes one of the prerequisites of production for the direct producer, and in which his ownership of land appears as the most advantageous condition for the prosperity of his mode of production. Just as capitalist production is conditioned in a general way on the expropriation of the laborers from their requirements of production, so capitalist agriculture demands the expropriation of the rural laborers from the land and their subordination to a capitalist, who carries on agriculture for the sake of profit. For the results of our analysis the objection, that other forms of landed property and of agriculture have existed or still exist, is quite irrelevant. Such an objection cannot apply to any one else but to those economists, who treat of the capitalist mode of production in agriculture, and of the form of landed property corresponding to it, as though it were not a historical but an eternal category.

For our purposes it is necessary to study the modern form of landed property, because it is our business to consider the typical conditions of production and commerce, which arise from the investment of capital in agriculture. Without this our analysis of capital would not be complete. We therefore confine ourselves exclusively to the investment of capital in agriculture strictly so-called, that is, capital invested in the production of the principal plant crop, on which a certain population lives. We may say wheat, because it is the principal article of food among the modern capitalistically developed nations (or mining instead of agriculture, because the laws of both are the same).

It is one of the great merits of Adam Smith to have shown that the ground rent for capital invested in the production of such crops as flax, dye stuffs, independent cattle raising, etc., is determined by the ground rent obtained from capital invested in the production of the principal article of subsistence. In fact no progress has been made in this since his time. What we might add in the way of exception or supplement belongs in a separate study of landed property, not here. Hence we shall not speak of landed property outside of the land destined for the production of wheat in the manner of exports, but shall merely refer to it occasionally by way of illustration.

For the sake of completeness we shall remark, that we include also water, etc., in the term land, so far as it has an owner and belongs as an accessory to the soil.

Landed property is conditioned on the monopolisation of certain portions of the globe by private persons, for the purpose of making these portions the exclusive spheres of their private will and keeping all others away from it.¹¹⁹ With this in mind, the problem is to ascertain the economic value, that is, the employment of this monopoly on the basis of capitalist production. With the legal power of these persons to use or misuse certain portions of the globe nothing is settled. The use of this power depends wholly upon economic conditions, which are independent of their will. The legal conception itself signifies nothing else but that the land owner may do with the soil what the owner of commodities may do with them. And this conception, this legal conception of free property in land, arises in the

ancient world only with the dissolution of the organic order of society, and in the modern world only with the development of capitalist production. Into Asia it has been imported by Europeans in but a few places. In that Part of our work, which deals with primitive accumulation (Volume I, chapter XXVI), we have seen that this mode of production presupposes on the one hand the separation of the direct producers from their position as mere attachments to the soil (in their capacity of bondsmen, serfs, slaves, etc.), on the other hand the expropriation of the mass of the people from the land. To this extent the monopoly of landed property is a historical premise, and remains the basis, of the capitalist mode of production, just as it does of all other modes of production, which rests on the exploitation of the masses in one form or another. But that form of landed property, which the capitalist mode of production meets in its first stages, does not suit its requirements. It creates for itself that form of property in land, which is adapted to its requirements, by subordinating agriculture to the dominion of capital. It transforms feudal landed property, tribal property, small peasants' property in mark communes, whatever may be their legal form, into the economic form corresponding to the requirements of capitalism. It is one of the great outcomes of the capitalist mode of production, that it transforms agriculture from a merely empirical and mechanically perpetuated process of the least developed part of society into a consciously scientific application of agronomics, so far as this is at all feasible under the conditions going with private property;¹²⁰ that it detaches property in land on the one side from the relations between master and servant, and on the other hand totally separates land as an instrument of production from property in land and land owners, for whom it represents merely a certain tribute of money, which he collects by force of his monopoly from the industrial capitalist, the capitalist farmer. It dissolves all these connections so thoroughly, that the owner of the land may spend his whole life in Constantinople, while his estates are in Scotland. Private property in land thus receives its purely economic form by discarding all its former political and social trappings and implications, in brief all those traditional accessories, which are denounced as a useless and absurd attachment by the industrial capitalists and their theoretical spokesmen in the heat of their struggle with landed property, as we shall see later. The rationalising of agriculture on the one hand and thus rendering it capable of operation on a social scale, and the reduction ad absurdum of private property in land on the other hand, these

are the great merits of the capitalist mode of production. Like all its other historical advances it bought these also by first completely pauperizing the direct producers.

Before we pass on to the problem itself, we must make a few more preliminary remarks in order to forestall misunderstanding.

The premises for a capitalist production in agriculture are these: The actual tillers of the soil are wage-laborers, employed by a capitalist, the capitalist farmer, who carries on agriculture merely as a special field of exploitation for his capital, an investment of his capital in a special sphere of production. This renting capitalist pays to the land owner, the owner of the soil exploited by him, a sum of money at definite periods fixed by contract, for instance annually (just as the borrower of money-capital pays a fixed interest), for the permission to invest his capital in this particular sphere of production. This sum of money is called ground-rent, no matter whether it is paid for agriculture soil, building lots, mines, fishing grounds, forests, etc. It is paid for the entire time, during which the land owner has rented his land to the capitalist by contract. Ground-rent, therefore, is that form, in which property in land realizes itself economically, that is, produces value. Here, then, we have all three classes together, which constitute the frame work of modern society, and they have divergent interests — wage-laborers, industrial capitalists, land owners.

Capital may be fixed in the soil, may be incorporated in it, either in a transient manner, as it is by improvements of a chemical nature, fertilization, etc., or more permanently, as in drainage canals, irrigation works, leveling, farm buildings, etc. In another place I have called the capital thus incorporated in the soil land-capital.¹²¹ It belongs in the categories of fixed capital. The interest on the capital thus incorporated in the soil and the improvements thus made in it as an instrument of production may form a part of the rent paid by the capitalist farmer to the land owner,¹²² but it does not constitute that ground-rent, strictly speaking, which is paid for the use of the soil as such, whether it be in a natural state or cultivated. In a systematic treatment of private property in land, which is not included in our plan, this part of the revenue of the land owner would have to be discussed at length. But a few words about it will suffice here.

The more transient investments of capital which go with the ordinary processes of production in agriculture, are made without exception by the capitalist farmer. These investments, like cultivation proper, improve the soil,¹²³ if cultivation is carried on in a moderately rational manner and does not reduce itself to a brutal spoilage of the soil, such as used to be in vogue among the former slave holders in the United States, a thing against which the land owners may provide by contract. In this way material land is transformed into land-capital. A cultivated field is worth more than an uncultivated one of the same natural quality. Likewise the more permanent fixed capitals, which are incorporated in the soil and worn out in longer time, are largely, and in some spheres often exclusively, invested by the capitalist farmer. But as soon as the time stipulated by contract has expired — and this is one of the reasons why the land owners seek to shorten the time of contract as much as possible when capitalist production develops — the improvements embodied in the soil become the property of the land owner as an inseparable part of the land. In the new contract, which the land owner makes, he adds the interest for the capital incorporated in the soil to the real ground-rent. And he does this whether he leases the land to the same capitalist who made these improvements or to some other capitalist farmer. His rent is thus increased; or, if he wishes to sell his land (we shall see immediately how its price is determined), its value has risen. He sells not merely the soil, but the improved soil, the capital incorporated in the soil for which he did not pay anything. Quite aside from the movements of real ground-rent, this is one of the secrets of the increasing enrichment of the land owners, of the continuous inflation of their rents, and of the growing money-value of real estate in proportion as economic development proceeds. Thus they pocket a result of social development brought about without their help, *fruges consumere nati*, they are born to consume the fruits of the earth. But this is at the same time one of the greatest obstacles to a rational development of agriculture, because the capitalist renter avoids all improvements and expenses, for which he cannot expect any returns during the time of his lease. We find this fact denounced as such an obstacle, not only in the 18th century by James Anderson, the actual discoverer of the modern theory of rent, who was also a practical capitalist farmer and an advanced agronomist for his time, but also in our own days by the opponents of the present constitution of landed property in England.

A. Walton, in his "History of the Landed Tenures of Great Britain and Ireland," London, 1865, says on this score: All the efforts of the numerous agricultural institutes in our country cannot accomplish any very important or really appreciable results in the actual progress of improved cultivation, so long as such improvements increase in a far higher degree the value of real estate and the size of the rent roll of the land owner, than they improve the condition of the tenant or the farm laborer. The tenants in general know quite as well as the land owner, his rent collector, or even the president of an agricultural society, that good drainage, ample manuring, and good management, together with an increased application of labor, cleaning the land thoroughly and working it over, will produce wonderful results, both in the improvement of the soil and in an increased production. But all this demands considerable expense, and the tenants also know very well, that no matter how much they may improve the soil or raise its value, the land owner will in the long run get the principal benefit of it in raised rents and increased land values....They are cunning enough to observe, what those speakers [land owners and their agents speaking at agricultural feasts] always forget to tell them, namely that the lion's share of all improvements made by the tenants must always pass ultimately into the pockets of the land owners....No matter how much the former tenant may have improved his leasehold, his successor will always find, that the land owner will raise the rent in proportion to the increased land value due to previous improvements. (Pages 96 and 97.)

In agriculture proper this process does not yet appear quite so plainly as when the land is used for building lots. The overwhelming part of the land used in England for building purposes, but not sold as a freehold, is rented by the land owners for 99 years, or for a shorter time if possible. After the lapse of this time the buildings fall into the hands of the land owner together with the land. The tenants are obliged, says Walton, to deliver the house to the great land owner in a good inhabitable condition after the expiration of the lease, after they have paid up to this time an exorbitant ground-rent. Hardly has the lease expired, when the agent or inspector of the landlord comes, inspects your house, takes care that you get it into good condition, takes possession of it and annexes it to the domain of his landlord. The fact is that if this system is permitted to exert its full effects for some time longer, the entire ownership of houses as well as of country real estate will

be in the hands of the great landed proprietors. The whole West End of London, north and south of Temple Bar, belongs almost exclusively to half a dozen great landlords, is rented at enormous ground-rents, and if the leases have not quite expired, most of them expire in rapid succession. The same applies in a greater or smaller degree to every city in the Kingdom. But even here this greedy system of exclusiveness and monopoly does not stop. Nearly all the docking facilities of our port cities are in the hands of the great land leviathans in consequence of the same process of usurpation. (L. c., .) Under these circumstances it is evident that if the census for England and Wales in 1861 gives the total population as 20,066,224 and the number of house owners as 36,032, the proportion of the owners to the number of houses and to the population would take on a very different aspect, if the great house owners were placed on one side and the small ones on the other.

This illustration of property in buildings is important. In the first place, it clearly shows the difference between real ground-rent and interest on fixed capital incorporated in the soil, which may form an addition to the ground-rent. The interest on buildings, like that on capital incorporated in the soil by the tenant, falls into the hands of the industrial capitalist, the building speculator, or the tenant, so long as the lease lasts, and has in itself nothing to do with the ground-rent, which must be paid annually at stated dates for the use of the soil. In the second place it shows, that the capital incorporated in the soil ultimately passes into the hands of the landlord together with the land, and that the interest on it helps to swell his rent.

Some writers, either acting as spokesmen of landlordism against the attacks of bourgeois economists, or endeavoring to transform the capitalist system of production from a system of antagonisms into one of "harmonies," as did Carey, have tried to represent ground-rent, the specific economic expression of private property in land, as identical with interest. For this would obliterate the antagonism between landlords and capitalists. The opposite method was employed in the beginning of capitalist production. In those days landed property was still regarded by popular conception as the primitive and respectable form of private property, while interest on capital was decried as usury. Dudley North, Locke and others, therefore represented interest on capital as a form analogous with ground-

rent, just as Turgot deduced the justification of interest from the existence of ground-rent. — Aside from the fact that ground-rent may, and does, exist in its pure form without any addition for interest on capital incorporated in the soil, these more recent writers also forget, that in this way the landlord does not only receive interest on the capital of other people that cost him nothing, but also pockets this capital of others without any compensating return. The justification of private property in land, like that of all other forms of property within a certain mode of production, is that the mode of production is itself a transient historical necessity, and this includes the conditions of production and exchange, which flow from it. It is true, as we shall see later, that property in land differs from the other kinds of property by the fact that it appears superfluous, and even noxious, at a certain stage of development, even from the point of view of capitalist production.

In another form, ground-rent may be confounded with interest and its specific character overlooked. Ground-rent assumes the shape of a certain sum of money, which the landlord draws annually out of the lease of a certain piece of the globe. We have seen that every sum of money may be capitalised, that is, considered as the interest on an imaginary capital. For instance, if the average rate of interest is 5%, then an annual ground-rent of 200 pounds sterling may be regarded as the interest on a capital of 4,000 pounds sterling. Ground-rent so capitalised forms the purchase price or value of the land, a category which is on its face irrational, just as the price of labor is, since the earth is not the product of labor and therefore has no value. But on the other hand a real relation in production is concealed behind this irrational form. If a capitalist buys land yielding a rent of 200 pounds sterling annually and pays 4,000 pounds sterling for it, then he draws the average interest of 5% on his capital of 4,000 pounds sterling, just as though he had invested this capital in interest-bearing papers or loaned it directly at 5% interest. It is the utilisation of a capital of 4,000 pounds sterling at 5%. On this assumption he would recover the purchase price of his estate in twenty years by its revenues. In England, therefore, the purchase price of land is calculated on so many years' purchase, and this is merely a different expression for the capitalisation of the ground-rent. It is in fact the purchase price, not of the land, but of the ground-rent yielded by it, calculated on the ordinary rate of interest. But this capitalisation of rent has for its premise the existence of rent, for rent cannot be explained and

derived from its own capitalisation. Its existence, independent of its sale, is rather the condition from which the inquiry must start.

It follows, then, that the price of land may rise or fall inversely as the rate of interest rises or falls, if we assume that ground-rent is a constant magnitude. If the ordinary rate of interest should fall from 5% to 4%, then the annual ground-rent of 200 pounds sterling would represent the annual self-expansion of a capital of 5,000 pounds sterling instead of 4,000 pounds sterling. The price of the same piece of land would thus have risen from 4,000 to 5,000 pounds sterling, or from 20 years' to 25 years' purchase. The reverse would take place in the opposite case. This is a movement of the price of land, which is independent of the movement of ground-rent itself and regulated only by the rate of interest. But as we have seen that the rate of profit has a tendency to fall in the course of social progress, and that the rate of interest has the same tendency, so far as it is regulated by the rate of profit; and since, furthermore, the rate of interest has a tendency to fall in consequence of the growth of loanable capital, aside from the influence of the rate of profit, it follows that the price of land has a tendency to rise, even independently of the movement of ground-rent and the prices of the products of the soil, of which the rent forms a part.

The mistaking ground-rent for the interest form, which it assumes for the buyer of the land — a mistake due to a complete unfamiliarity with the nature of ground-rent — must lead to the most absurd conclusions. Since landed property is considered, in all old countries, as a particularly noble form of property, and its purchase also as an eminently safe investment of capital, the rate of interest at which ground-rent is bought is generally lower than that of other investments of capital for a long time, so that a buyer of real estate draws, for instance, only 4% on his purchase price, whereas he would draw 5% for the same capital in other investments. In other words, he pays more capital for the ground-rent than he would for the same amount of income in other investments. This leads Mr. Thiers to conclude in his utterly valueless work on *La Propriété* (a reprint of a speech of his made in 1849 against Proudhon in the French National Assembly) that ground-rent is low, while it proves merely that its purchase price is high.

The fact that capitalised ground-rent represents itself as the price or value of land, so that the earth is bought and sold like any other commodity, serves to some apologists as a justification of private property in land, seeing that the buyer pays an equivalent for it the same as he does for other commodities, and that the major portion of property in land has changed hands in this way. The same reason would, in that case, serve also to justify slavery, since the returns from the labor of the slave, whom the slave holder has bought, represent merely the interest on the capital invested in this purchase. To derive from the sale and purchase of ground-rent a justification for its existence signifies to justify its existence by its existence.

It is very important for a scientific analysis of ground-rent, that is of the independent and specifically economic form of property in land on the basis of capitalist production, to study it in its pure form and free from all falsifying and obliterating by-work. And it is no less important for an understanding of the practical effects of property in land, even for a theoretical comprehension of a multitude of facts, which run counter to the conception and nature of ground-rent and yet appear as modes of existence of ground-rent, to know the elements which give rise to such obscurities in theory.

In practice everything appears naturally as ground-rent that is paid in the form of lease money by the tenant to the landlord for the permission of cultivating the soil. Whatever may be the composition of this tribute, whatever may be its sources, it has this in common with real ground-rent that the monopoly of the so-called owner of a piece of the globe enables him to levy such a tribute and impose such a tax. This tribute furthermore shares with the real ground-rent the fact that it determines the price of land, which, as we have indicated above, is nothing but the capitalised income from the lease of the land.

We have already seen, that the interest for the capital incorporated in the soil may form one of those foreign ingredients in ground-rent, an element which must become a continually growing addition to the total rent of a certain country in proportion as economic development proceeds. But aside from this interest it is possible that the lease money may conceal a

deduction from the average profit or from the normal wages, or both, being made up of them either in part or wholly, so that in some cases it may not represent any real ground-rent at all and the soil may be valueless. This portion of the profit, or of wages, appears then as ground-rent, because instead of falling normally into the hands of the industrial capitalist or the wage worker, it is paid to the land-lord in the form of lease money. Economically speaking neither the one nor the other of these portions constitutes any ground-rent; but in practice they constitute some of the revenue of the landlord, an economic utilisation of his monopoly, just as real ground-rent does, and they have a determining influence on land prices just as ground-rent has.

We are not now speaking of conditions, in which ground-rent, the form of landed property adapted to the capitalist mode of production, formally exists without the capitalist mode of production itself, so that the tenant is not an industrial capitalist, nor the mode of his management a capitalist one. Such is the case in Ireland. The tenant is here generally a small farmer. What he pays to the landlord in the shape of rent absorbs frequently not merely a part of his profit, that is, of his own surplus-labor, to which he is entitled as the possessor of his own instruments of production, but also a part of his normal wages, which he would receive under different conditions for the same amount of labor. Besides, the landlord, who does not do anything for the improvement of the soil, also expropriates him from his small capital, which he incorporates for the greater part in the soil by his own labor, just as a usurer would do under similar circumstances. Only the usurer would at least risk his own capital in the operation. This continual robbery is the center of the disputes over the Irish Land Bill, which has for its principal aim to compel the landlord, when giving notice to his tenant to vacate, should pay him an indemnity for the improvements made by him in the soil, or for the capital incorporated by him in the land. Palmerston used to meet this demand with the cynical answer: "The House of Commons is a house of landlords."

Nor do we speak of exceptional circumstances, in which the landlord may enforce a high rent even in countries with a capitalist production, although this rent may not be in any way connected with the product of the soil. Of such a nature is the renting of small patches of ground to laborers in

English factory districts, either for small gardens or for amateur agriculture in spare hours. (Reports of Inspectors of Factories.)

We are speaking of ground-rent in countries with a developed capitalist production. Among English tenants, for instance, there is a number of small capitalists, who are destined and compelled by education, training, tradition, competition, and other circumstances, to invest their capital as tenants in agriculture. They are compelled to be satisfied with less than the average profit, and to yield up a part of it to the landlords for rent. This is the only condition on which they are permitted to invest their capital in the soil, in agriculture. Since the landlords exert everywhere a considerable, in England even an overwhelming, influence on legislation, they are in a position to exploit this for the purpose of grinding down the entire class of tenants. The corn laws of 1815, for instance, a bread tax confessedly imposed upon the country for the purpose of securing for the idle landlords a continuation of their abnormally increased rentals during the anti-Jacobin wars, had indeed the effect, with the exception of a few extraordinarily rich years, of keeping the prices of agricultural products above the level which they could have held in free competition. But they did not have the effect of keeping prices at that level, which had been ordered by the law-making landlords to serve as standard prices in such a way as to form the legal limit for the importation of foreign corn. But the leases were made out under the impression created by these normal prices. As soon as the illusion passed away, a new law was made, with new normal prices, which were as much an impotent expression of the greedy land-lord's phantasy as the old ones. In this way the tenants were cheated from 1815 to the thirties. Hence we have during all this period the standing subject of agricultural distress. And with it we have during this period the expropriation and the ruin of a whole generation of tenants, and the appropriation of their places by a new class of capitalists.¹²⁴

A much more general and important fact, however, is the depression of the wages of the actual farm laborers below their normal average, so that a portion of the wages is deducted in order to become a part of the lease money and thus flowing into the pockets of the landlord instead of the laborer under the disguise of ground-rent. This is the case quite generally in England and Scotland, with the exception of a few favorably situated

counties. The inquiries of the Parliamentary Committees into the scale of wages made before the passing of the corn laws in England — so far the most valuable and almost unexploited contributions to a history of wages in the 19th century, and at the same time a monument of disgrace erected for themselves by the English aristocracy and bourgeoisie — proved convincingly and beyond a doubt that the high rates of rent and the corresponding raise in the land prices during the anti-Jacobin wars, were due in part to no other cause but the deductions from wages and the depression of wages even below the physical minimum. In other words, a part of the wages had been paid over to the landlords. Various circumstances such as the depreciation of money, the handling of the poor laws in the agricultural districts, etc., had made these operations possible, at a time when the incomes of the tenants were rising enormously and the landlords amassed fabulous riches. Yes, one of the main arguments for the introduction of the corn laws, used by both tenants and landlords, was that it was physically impossible to depress the wages of the farm laborers still more. This condition of things has not been materially altered, and in England as well as in all European countries a portion of the normal wages is absorbed by the ground-rent the same as ever. When Count Shaftsbury, then Lord Ashley, one of the philanthropic aristocrats, was so extraordinarily moved by the condition of the English factory laborers and acted as their spokesman in Parliament during the agitation for a ten hour day, the spokesmen of the industrials got their revenge by publishing statistics on the wages of the agricultural laborers in the villages belonging to him (see Volume I, chapter XXV, 5e, *The British Agricultural Proletariat*), which showed clearly, that a portion of the ground-rent of this philanthropist consisted of the loot, which his agents filched for him out of the wages of the agricultural laborers. This publication is also interesting for the reason, that the facts exposed by it may rank in the same class with the worst exposures made by the Committees in 1814 and 1815. As soon as circumstances permit of a temporary raise in the wages of the agricultural laborers, a cry goes up from the capitalist tenants to the effect that a raising of the wages to their normal level, as customary in other lines of industry, would be impossible and would ruin them, unless ground-rent were reduced at the same time. This is a confession, that the tenants deduct a portion from the wages of the laborers under the name of ground-rent and pay it over to the landlords. For instance, from 1849 to 1859 the wages of the agricultural

laborers rose in England through a combination of overwhelming circumstances, such as the exodus from Ireland, which cut off the supply of agricultural laborers coming from that country; an extraordinary absorption of the agricultural population by the factories; a demand for soldiers to go to war; an exceptional emigration to Australia and the United States (California), and other causes which need not be mentioned here. At the same time the average prices of grain fell by more than 16% during this period, with the exception of the poor agricultural years from 1854 to 1856. The tenant capitalists shouted for a reduction of their rents. They succeeded in single cases. But on the whole they failed to get what they wanted. They sought refuge in a reduction of the cost of production, among other things by introducing steam engines and new machinery in abundance, which partly replaced horses and crowded them out of the business, but partly also created an artificial overpopulation by throwing agricultural laborers out of work and thereby causing a fall in wages. And this took place in spite of the general relative decrease of the agricultural population during that decade, compared to the growth of the total population, and in spite of the absolute decrease of the agricultural population in some purely agricultural districts.¹²⁵ In the same way Fawcett, then professor of political economy at Cambridge, who died in 1884 as Postmaster General, said at the Social Science Congress, October 12, 1865: "The agricultural laborers began to emigrate and the tenants began to complain, that they would not be able to pay such high rents as they had been accustomed to pay, because labor became dearer in consequence of emigration." Here, then, the high ground-rent is directly identified with low wages. And so far as the level of the prices of land is determined by this circumstance increasing the rent, a rise in the value of the land is identical with a depreciation of labor, a high price of land with a low price of labor.

The same is true of France. "The price of rent rises, because the prices of bread, wine, meat, vegetables and fruit rise on the one side, while on the other the price of labor remains unchanged. If the older people compare the bills of their fathers, taking us back about 100 years, they will find that the price of one day's labor was then the same in rural France as it is now. The price of meat has trebled since them....Who is the victim of this revolution? Is it the rich, who is the proprietor of the estate, or the poor who works it?...The raising of the prices of rent is the proof of a national disaster." (Du

Mécanisme de la Société en France et en Angleterre. Par M. Rubichon, Second edition, Paris, 1837, .)

We now give some illustrations of rent representing deductions either from the average profit or from the average wages.

The above quoted Morton, real estate agent and agricultural engineer, says that the observation has been made in many localities that the rent for large estates is smaller than for small ones, because “competition for the latter is generally greater than for the former, and because small tenants, who are rarely able to take up any other business but farming, are frequently willing to pay a rent, which they themselves know to be too high, pressed by the want of finding some other business.” (John C. Morton, *The Resources of Estates*. London, 1858, .)

However, he is of the opinion that this difference is gradually disappearing in England, and he attributes this largely to the emigration of the class of small tenants. The same Morton gives an illustration, in which evidently the wages of the tenant himself, and still more surely of the laborers, suffer a deduction for ground-rent. This takes place in the case of estates of 70 to 80 acres, who cannot keep a two-horse plow. “Unless the tenant works as diligently with his own hands as any laborer, he cannot make out on his lease. If he leaves the execution of the work to his men and confines himself to superintending them, he will most likely find very quickly that he is unable to pay his rent.” (L. c., .) Morton concludes, therefore, that unless the tenants of a certain locality are very poor, the leaseholds should not be smaller than 70 acres, so that the tenants may keep two or three horses.

Extraordinary wisdom of Monsieur Léonce de Lavergne, Membre de l’Institut et de la Société Centrale d’Agriculture. In his *Economic Rurale de l’Angleterre* (quoted from the English translation, London, 1855), he makes the following comparison of the annual advantages from cattle, that work in France but not in England, where they are replaced by horses :

FRANCE	ENGLAND	Milk...	4 million p.st.	Milk...	16 million p.st.
Meat...	16 million p.st.	Meat...	20 million p.st.	Labor...	8 million p.st.
Labor...	28 million p.st.				36 million p.st.

But the higher amount for England is obtained here, according to his own statement, because milk is twice as dear in England than in France, while he counts the same prices for meat in both countries ; therefore the English milk product reduces itself to 8 million pounds sterling, and the total product to 28 million pounds sterling, the same as in France. It is indeed a strong dose, that Mr. Lavergne lumps the quantities and price differences together in his calculation, when England produces certain articles more expensively than France, so that this appears as an advantage of English agriculture, whereas it signifies at best only a higher profit for tenants and landlords.

That Mr. Lavergne is not only familiar with the advantages of English agriculture, but also believes in the prejudices of the English tenants and landlords, is proved by him on page 48: "One great disadvantage is generally connected with grain plants...they exhaust the soil that bears them." Mr. Lavergne believes not only that other plants do not do so, but he also believes that leguminous crops and root crops enrich the soil: "Leguminous plants draw the principal elements of their growth out of the air, while they give back to the soil more than they take from it; therefore they help both directly and indirectly through their return in the shape of animal manure to make good in a double way the damage caused by grain crops and other exhausting crops; hence it is a matter of principle that they should at least alternate with such crops; in this consists the Norfolk rotation." (Pages 50 and 51.)

No wonder that Mr. Lavergne, who believes these fairy tales of the English rural mind, also believes that the wages of the English farm laborers have lost their abnormality since the repeal of the corn tax. See what we have said on this point in another place, Volume I, chapter XXV, 5c, pages 739 to 766. But let us also listen to Mr. John Bright's speech in Birmingham, December 14, 1865. After mentioning the 5 million families that are not represented in Parliament, he continues: "Among these are one million, or rather more than one million in the United Kingdom, who are put down on the luckless list of paupers. Then there is still another million, who are holding themselves just above pauperism, but who are continually in danger of likewise becoming paupers. Their condition and prospects are

not any better. Now take a look at the ignorant lower strata of this portion of society. Consider their outcast condition, their poverty, their complete hopelessness. Even in the United States, even in the southern states during the reign of slavery, every negro looked forward to some jubilee year. But these people, this mass of the lowest strata of our country, I am here to express it, have neither the faith in any improvement nor even a longing for it. Did you read the other day that item about John Cross, a farm laborer of Dorsetshire? He worked six days in the week, had an excellent character from his employer, for whom he had worked 24 years for a weekly wage of 8 sh. John Cross had to keep a family of seven children in his hut out of this wage. In order to warm his sickly wife and her suckling babe, he took, or legally speaking he stole, a wooden hurdle worth six pence. For this crime he was sentenced to 14 or 20 days' imprisonment by the justices of the peace. I can tell you that many thousands of cases like that of John Cross may be found in the whole country, and particularly in the South, and that their condition is such, that so far the most sincere investigator has not been able to solve the secret, how they keep body and soul together. And now throw your glances over the whole country and look at those 5 million families and the desperate condition of this stratum of them. Can we not say truly that the mass of the nation excluded from the suffrage toils and toils again and knows almost no rest? Compare them with the ruling class — but if I do that I shall be accused of communism...but compare this great toiling and suffrageless nation with that part which may be regarded as the ruling class. Look at their wealth, their showiness, their luxury. Look at their weariness — for there is a weariness also among them, but it is the weariness of satiety — and see how they hasten from place to place, as though it were only a question of discovering new pleasures.” (Morning Star, December 15, 1865.)

We will show hereafter, in what manner surplus-labor, and consequently surplus-products, are confounded with ground-rent, which is, at least under the capitalist mode of production, qualitatively and quantitatively a specifically determined part of the surplus-product. The natural basis of surplus-labor in general, that is a natural condition without which such labor cannot be performed, is that nature must supply, either in animal or vegetable products of the soil or in fisheries, etc., the necessary means of subsistence by an expenditure of labor which does not consume the entire

working day. This natural productivity of agricultural labor (which implies here the labor of gathering, hunting, fishing, cattle raising) is the basis of all surplus-labor; so is all labor primarily and originally directed toward the appropriation and production of food. (The animal supplies at the same time skins for warmth in colder climates; also cave dwellers, etc.)

The same confusion between surplus-product and ground-rent, differently expressed, is shown by Mr. Dove. Originally agricultural and industrial labor are not separated. The second joins into the first. The surplus-labor and the surplus-product of the farming tribe, the house commune or family, comprise both agricultural and industrial labor. Both go hand in hand. Hunting, fishing, agriculture are impossible without suitable tools. Weaving, spinning, etc., were first carried on as side occupations to farming.

We have shown previously, that in the same way in which the labor of the individual workman may be separated into necessary and surplus-labor, the aggregate labor of the working class may be divided so that that portion, which produces the total means of subsistence for the working class (including the means of production required for this purpose) performs the necessary labor for the whole society. The labor performed by all the remainder of the working class may then be regarded as surplus-labor. But the necessary includes by no means only agricultural labor, but also that labor which produces all other products that necessarily pass into the average consumption of the laborer. Socially speaking, some perform only necessary, others only surplus-labor, and vice versa. It is but a division of labor between them. It is the same with the division of labor between agricultural and industrial laborers in general. The purely industrial character of labor on the one side is offset by the purely agricultural one on the other. This purely agricultural labor is by no means natural, but is rather a product, and a very modern one at that, which has not yet been acquired everywhere, of social development, and it corresponds to a very definite stage of development. Just as a portion of the agricultural labor is materialised in products, which either minister only to luxury or serve as raw materials in industry, but do not serve as food, particularly not as food for the masses, so a portion of the industrial labor is materialised in products, which serve as necessary means of consumption of both the

agricultural and industrial laborers. It is a mistake to consider this industrial labor, from a social point of view, as surplus-labor. It is in part as much necessary labor as the necessary portion of the agricultural labor. It is likewise but a separated form of a part of industrial labor which was formerly naturally connected with agricultural labor, it is a necessary and mutual supplement to the purely agricultural labor, which is now separated from it. (From a purely material point of view 500 mechanical weavers may produce surplus-fabrics to a far greater degree, that is, more than is required for their own clothing.)

It should finally be remembered in the study of the various forms which appear as ground-rent, that is, of the lease money paid under the name of ground-rent to the landlord for the use of the land for the purposes of production or consumption, that the price of things, which have in themselves no value, not being the products of labor, such as the land, or which at least cannot be reproduced by labor, such as antiquities, works of art of certain masters, etc., may be determined by many accidental combinations. In order to sell a thing, nothing more is required than that it can be monopolised and alienated.

There are three great errors, which should be avoided in the study of ground-rent, and which obscure its analysis.

Confusion of the various forms of rent, which correspond to different stages of development of the process of social production.

Whatever may be the specific form of rent, all types of it have this in common that the appropriation of rent is that economic form, in which property in land realises itself, and that ground-rent on its part is conditioned on the existence of private property in land, the ownership of certain portions of the globe by certain individuals. The owner may be the individual representing the community, as in Asia, Egypt, etc., or this private ownership in land may be merely accessory to the ownership of the persons of the direct producers by some individuals, as under the slave or serf system, or it may be a purely private ownership of nature by nonproducers, a mere title to land, or finally it may be a relation to the soil which, as in the case of colonists and small peasants owning land, seems

included under a system of isolated and unsocial labor in the appropriation and production of the products of certain pieces of land by the direct producers.

This common element in the various forms of rent, namely that of being the economic realisation of property in land, a legal fiction by grace of which certain individuals have an exclusive right to certain pieces of the globe, misleads into overlooking the differences.

All ground-rent is surplus-value, the product of surplus-labor. In its undeveloped form, as natural rent (rent in kind), it is as yet directly the surplus-product itself. This gives rise to the mistaken idea that the rent corresponding to the capitalist mode of production is explained by merely explaining the general prerequisites of surplus-value and profit, whereas this ground-rent is always a surplus over and above profit. It is a peculiar and specific portion of surplus-value, over and above that portion of the value of commodities, which is known as profit and consists itself of surplus-value (surplus-labor). The general conditions for the existence of surplus-value and profit are: The direct producers must work beyond the time necessary for the reproduction of their own labor-power. They must perform surplus labor in general. This is the subjective condition. The objective condition is that they must be able to perform surplus-labor. The natural conditions must be such that a part of their available labor time suffices for their reproduction and selfmaintenance as producers, that the production of their necessary means of subsistence shall not consume their whole labor-power. The fertility of nature forms a limit here, a starting point, a basis. The development of the social productivity of their labor forms the other limit. Still more strictly speaking, since the production of means of subsistence is the very first condition of their existence and of all production, the labor used in this production, that is the agricultural labor in the widest economic meaning, must be productive enough, so that it will not absorb the entire available labor time in the production of means of subsistence for the direct producers. Agricultural surplus-labor and an agricultural surplus-product must be possible. More widely applied, it means that the total agricultural labor, both necessary and surplus-labor, of a part of society suffices to produce the necessary subsistence for the whole society, including the laborers who are not agricultural. It means that this

great division of labor between farmers and industrials must be possible, also that between farmers producing subsistence and farmers producing raw materials. Although the labor of the producers of subsistence consists of necessary and surplus-labor, so far as their own point of view goes, it represents from the social standpoint only the labor necessary to produce the social subsistence. The same takes place in the case of division of labor within society as a whole, as distinguished from division of labor in the individual workshop. It is the labor necessary for the production of particular articles, for the satisfaction of some particular need of society. If this division is proportional, then the products of the various groups are sold at their values (at a later stage of development at their prices of production), or at prices which are modifications of their values or prices of production due to general laws. It is indeed the law of value enforcing itself, not with reference to individual commodities or articles, but to the total products of the particular social spheres of production made independent by division of labor. Every commodity must contain the necessary quantity of labor, and at the same time only the proportional quantity of the total social labor time must have been spent on the various groups. For the use-value of things remains a prerequisite. The use-value of the individual commodities depends on the particular need which each satisfies. But the use-value of the social mass of products depends on the extent to which it satisfies in quantity a definite social need for every particular kind of product in an adequate manner, so that the labor is proportionately distributed among the different spheres in keeping with these social needs, which are definite in quantity. (This point is to be noted in the distribution of capital to the various spheres of production.) The social need, that is the use-value on a social scale, appears here as a determining factor for the amount of social labor which is to be supplied by the various particular spheres. But it is only the same law, which showed itself in the individual commodity, namely that its use-value is the basis of its exchange-value and thus of its surplus-value. This point has any bearing upon the proportion between necessary and surplus-labor only in so far as a violation of this proportion makes it impossible to realise the value of the commodities and the surplus-value contained in it. For instance, take it that proportionally too much cotton goods have been produced, although only the labor-time necessary for this total product under the prevailing conditions is realised in it. But too much social labor has been expended in this particular line, in other words, a

portion of this product is useless. The whole of it is therefore sold only as though it had been produced in the necessary proportion. This quantitative limit of the quota of social labor available for the various particular spheres is but a wider expression of the law of value, although the necessary labor time assumes a different meaning here. Only just so much of it is required for the satisfaction of the social needs. The limitation is here due to the use-value. Society can use only so much of its total labor for this particular kind of products under the prevailing conditions of production. But the subjective and objective conditions of surplus-labor and surplus-value in general have nothing to do with the peculiar form of either the profit or the rent. These conditions apply to surplus-value as such, no matter what special form it may assume. Hence they do not explain ground-rent.

It is precisely the self-expansion of private property, the development of ground-rent, which reveals the characteristic peculiarity, that its amount is by no means determined by the actions of its recipient, but by the independent development of social labor, in which he does not take part. It may easily happen, therefore, that something is regarded as a peculiarity of rent (and of the products of agriculture in general), which is really a common feature of all lines of production and all their products on the basis of the production of commodities, or, more strictly speaking, of capitalist production.

The amount of ground-rent (and with it the value of the soil) develops with the progress of social advance as a result of the total labor of society. On the one hand this leads to a growth of the market and of the demand for products of the soil, on the other it stimulates the demand for the land itself, which is a prerequisite of competitive production in all lines of business, even in those which are not agricultural. Speaking strictly of real-ground rent, this rent, and with it the value of the soil, develops with the market for the products of the soil, and thus with the increase of the other than agricultural population, with its needs and demand for either means of subsistence or raw materials. It is the nature of capitalist production to reduce the agricultural population continually as compared to the non-agricultural, because in industry (strictly speaking) the increase of the constant capital compared to the variable capital goes hand in hand with an absolute increase, though relative decrease, of the variable capital; whereas

in agriculture the variable capital required for the exploitation of a certain piece of land decreases absolutely and cannot increase, unless new land is taken into cultivation, which implies a still greater previous growth of the non-agricultural population.

In fact we are not dealing here with a characteristic peculiarity of agriculture and its products. On the contrary, the same applies to all other lines of production and products on the basis of a production of commodities and of its absolute form, capitalist production.

These products are commodities, use-values, which have an exchange-value which can be realised, converted into money, only to the extent that other commodities form an equivalent for them, that other products face them as commodities and values. They have an exchange-value to the extent that they are not produced as immediate means of subsistence for the producers themselves, but as commodities, as products which become use-values only by their conversion into exchange-values (money), by being gotten rid of. The market for these commodities develops through the social division of labor; the separation of the productive labor into various departments transforms their respective products mutually into commodities, into mutual equivalents, makes them serve mutually as markets. This is in no way peculiar to agricultural products.

Rent can develop as money-rent only on the basis of a production of commodities, more strictly of capitalist production, and it so develops in proportion as the agricultural production becomes a production of commodities. This is the same proportion in which other than agricultural lines of production develop independently of agriculture, for to that extent does the agricultural product become a commodity, an exchange-value, a value. To the same extent that the production of commodities develops as a capitalist production, and as a production of value, does the production of surplus-value and surplus-products proceed. But to the same extent that this continues does property in land acquire the faculty of capturing an ever increasing portion of this surplus-value by means of its land monopoly. Thereby it raises its rent and the price of the land itself. The capitalist performs at least an active function himself in the development of surplus-value and surplus-products. But the land owner has but to capture his

growing share in the surplus-product and the surplus-value created without his assistance. It is this which is the characteristic peculiarity of his position, and not the fact that the value of the products of the soil and thus of the land increases in proportion as the market for them expands, the demand grows and with it the world of commodities which are not agricultural products, the mass of producers and products outside of agriculture. But as this is done without the assistance of the landowner, it appears as something specifically his own, that measures of value, measures of surplus-value, and the conversion of a portion of surplus-value into ground-rent should depend upon the process of social production, on the development of the production of the commodities in general. For this reason a man like Dove wants to develop rent out of this element. He says that rent does not depend upon the mass of agricultural products, but upon their value; but this depends upon the mass and productivity of the non-agricultural population. But it is also true of all other products that they cannot develop the character of commodities, unless the mass, the variety and the succession of other commodities form equivalents for them. We have shown this previously in the discussion of the general nature of value. On the one hand the exchangeability of a certain product depends altogether on the multiplicity of commodities existing outside of it. On the other hand this circumstance determines in particular to what extent this product shall be put out as a commodity.

No producer, whether an industrial or farmer, considered by himself alone, produces value or commodities. His product becomes a commodity only in definite social interrelations. It becomes a commodity, in the first place, to the extent that it represents social labor, so that the individual producer's labor counts as a part of the general social labor. And in the second place this social character of his labor appears impressed upon his product through its pecuniary character and through its general exchangeability determined by its price.

Instead of explaining rent, such vagaries confine themselves to explaining merely surplus-value in general, or, still more absurdly, surplus-products in general, and on the other hand they make the mistake of ascribing a character, which belongs to all products in their capacity as commodities, to agricultural products exclusively. This is still more

vulgarised by those who pass from a general analysis of value over to the realisation of a certain commodity's value. Every commodity can realise its value only in the process of circulation, and whether it realises its value, and to what extent it does so, depends on the prevailing market conditions.

It is not a peculiarity of ground-rent, then, that the products of agriculture develop into values and as values, that they face other commodities as commodities, and that products not agricultural face them as commodities, or that they develop as specific expressions of social labor. The peculiarity of ground-rent is rather that in proportion as the conditions develop, in which agricultural products develop as commodities (values), and in which they can realise their values, so does also property in land develop the power to appropriate an increasing portion of these values, which were created without its assistance, and so does an increasing portion of the surplus-value assume the form of ground-rent.

CHAPTER XXXVIII. DIFFERENTIAL RENT. GENERAL REMARKS.

IN the analysis of ground-rent we shall start from the assumption, that products paying such a rent, that is, products a portion of whose surplus-value and general price resolves itself into ground-rent, are sold at their prices of production, like all other commodities. It suffices for our purposes to confine ourselves to products of agriculture and mining. In other words, their selling prices are made up of the elements of their cost (the value of the consumed constant and variable capital) plus a profit, which is determined by the average rate of profit and calculated on the total capital advanced, whether consumed or not consumed. We assume, then, that the average selling prices of these products are equal to their prices of production. The question is now, how can a ground-rent develop under these conditions, how can a portion of the profit become converted into ground-rent, so that a portion of the prices of the commodities falls into the hands of the landlord.

In order to show the general character of this form of ground-rent, we assume that most of the factories of a certain country are driven by steam engines, while a certain smaller number of them are driven by natural waterfalls. Let us further assume that the price of production in those industries amounts to 115 for a quantity of commodities which have consumed a capital of 100. The 15% of profit are calculated, not merely on the consumed capital of 100, but on the total capital invested in the production of this value in the commodities. We have previously shown that this price of production is not determined by the individual cost-price of every single producing industrial, but by the cost-price required on an average for the commodity under the average conditions of capital in the entire sphere of production. It is, in fact, the market price of production, as distinguished from its oscillations. For it is in the form of the market price, and in a wider sense of the regulating market price, or market price of production, that the nature of value asserts itself in commodities. It becomes evident, in this way, that it is not determined by the labor time necessary in the case of any individual producer for the production of a certain quantity

of commodities, or of some individual commodity, but by the socially necessary labor time. This is that quantity of labor time, which is necessary for the production of the socially required total quantity of commodities of any kind on the market under the existing average conditions of social production.

As definite figures are immaterial in this case, we shall furthermore assume that the cost price in the factories driven by water power is only 90 instead of 100. Since the regulating market price of production of this quantity of commodities is 115, with a profit of 15%, the factories driven by water power will also sell their commodities at 115, the average price regulating the market price. Their profit would then be 25 instead of 15; the regulating market price of production would allow them a surplus-profit of 10%, not because they sell their commodities above the price of production, but because they sell them at the price of production, because their commodities are produced, or their capital expanded, under exceptionally favorable conditions, under conditions, which are above the average prevailing in this sphere.

Two things become evident at once.

The surplus-profit of the producers, who use the natural waterfall as motive power, is in the same class with all surplus-profit (and we have already analysed this category when discussing the prices of production), which is not the result of mere transactions in the sphere of circulation, of mere fluctuations of market prices. This surplus-profit, then, is likewise equal to the difference between the individual price of production of these favored producers and the general social price of production regulating the market in this entire sphere. This difference is equal to the excess of the general price of production of the commodities over their individual price of production. The two regulating limits of this excess are on the one hand the individual cost price, and thus the individual price of production, on the other hand the general price of production. The value of the commodities produced with water power is smaller, because a smaller quantity of labor is required for their production, namely less labor materialised in the constant capital. The labor here employed is more productive, its individual power of production is greater than that employed in the majority of the factories of

the same kind. Its greater productive power is shown in the fact that it requires a smaller quantity of constant capital, a smaller quantity of materialised labor, than the others. It also requires less living labor, because the water wheel need not be heated. This greater individual power of production of the employed labor reduces the value, and at the same time the cost price and price of production of the commodity. For the individual industrial capitalist this expresses itself in a lower cost price of his commodities. He has to pay for less materialised labor, and less wages for less labor-power employed. Since the cost price of his commodities is smaller, his individual price of production is also smaller. His cost price is 90 instead of 100. His individual price of production would therefore be only $103\frac{1}{2}$ instead of 115 ($100: 115 = 90: 103\frac{1}{2}$). The difference between his individual price of production and the general one is limited by the difference between his individual cost price and the general one. This is one of the magnitudes which form the limits of his surplus-product. The other is the magnitude of the general price of production, into which the average rate of profit enters as a regulating factor. If coal should become cheaper, the difference between his individual cost-price and the general cost-price would decrease, and with it his surplus-profit. If he should be compelled to sell his commodities at their individual value, or at the price of production determined by its individual value, then the difference would disappear. It is on the one side a result of the fact that the commodities are sold at their general market-price, the price brought about by the equalisation of individual prices through competition, on the other side a result of the fact that the greater individual productivity of the laborers employed by him does not benefit the laborers, but their employer, as does all productivity of labor. This productivity represents itself as a faculty of capital.

Since the level of the general price of production is one of the limits of the surplus-product, the level of the average rate of profit being one of its factors, it can have no other source but the difference between the general and the individual price of production, and consequently the difference between the general and the individual rate of profit. An excess of this difference would imply the sale of products above the price of production regulated by the market, not at this price.

So far as the surplus profit of the manufacturer using natural water power instead of steam for motive power does not differ in any way from any other surplus profit. All normal surplus profit, that is all surplus profit not due through accidental sales or fluctuations of the market price, is determined by the difference between the individual price of production of the commodities of these particular capitals and the general price of production, which regulates in a general way the market prices of the commodities produced by the capitals of this sphere of production, or the market prices of the commodities of the total capital invested in this sphere of production.

But now we come to the difference.

To what circumstance does the industrial capitalist in the present case owe his surplus-profit, the surplus resulting for him personally from the price of production regulated by the average rate of profit?

He owes it in the last resort to a natural power, the motive power of water, which is found ready at hand in nature and which is not itself a product of labor like coal, which transforms water into steam. The water has no value, it need not be paid by an equivalent, it costs nothing. It is a natural agency of production, which is not produced by labor.

But this is not all. The manufacturer who works with a steam engine also employs natural powers, which cost him nothing and yet make his labor more productive and, to the extent that they cheapen the manufacture of the means of subsistence required for the laborers, increase the surplus-value and with it the profit. These natural powers are quite as much monopolised by capital as the natural powers of social labor arising from co-operation, division, etc. The manufacturer pays for the coal, but not for the faculty of the water to alter its aggregate state, of passing over into steam, not for the elasticity of the steam, etc. The monopolisation of natural powers, that is of the increased productivity of labor due to them, is common to all capital working with steam engines. It may increase that portion of the product of labor which represents surplus-value as against that portion which is converted into wages. To the extent that it does this, it raises the general rate of profit, but it does not make any surplus-profit, for this consists of the

excess of the individual profit over the average profit. The fact that the application of a natural power, of a waterfall, creates a surplus-profit in this case, cannot therefore be due solely to the circumstance that the increased productivity of labor is here due to a natural force. There must be still other modifying circumstances.

Look at the reverse side. The mere application of natural powers to industry may influence the level of the general rate of profit, because it affects the quantity of labor necessary to produce the means of subsistence. But in itself it does not create any deviations from the general rate of profit, and this is the point in which we are interested here. Furthermore, the surplus-profit, which some individual capital may ordinarily realise in its particular sphere of production — for the deviations of the rates of profits in the various spheres of production are continually balanced by competition into an average rate — are due, aside from accidental deviations, to a reduction of the cost-price, of the cost of production. This reduction arises either from the fact that a capital is used in greater than ordinary quantities, so that the dead expenses of the production are reduced, while the general causes increasing the productivity of labor, such as co-operation, division, etc., can exert themselves with a higher degree of intensity, their field of expression being larger. Or it may arise from the fact that, aside from the greater volume of the invested capital, better methods of labor, new inventions, improved machinery, chemical secrets in manufacture, etc., in short new and improved means of production and methods are used, which are above the average. The reduction of the cost price and the surplus profit arising from it arise here from the manner, in which the self-expanding capital is invested. They arise either from the circumstance that it is concentrated in one hand in extraordinarily large masses (a circumstance which is neutralised when capitals of the same size become the average), or from the circumstance that a capital of a certain size expands itself under exceptionally favorable circumstances (a circumstance which is neutralised as soon as the exceptional method of production becomes general or is superseded by a still more developed one).

The cause of the surplus profit, then, arises here from the capital itself (which includes the labor set in motion by it); it is either due to the greater size of the capital employed, or to its more improved application; and there

is no particular reason why all the capital in the same sphere of production should not be invested in the same way. In fact, the competition between the capitals tends to neutralise their differences more and more. The determination of value by the socially necessary labor time asserts itself by the cheapening of commodities and the necessity of making commodities under the same favorable conditions. But it is different with the surplus profit of the industrial capitalist who uses water power. The increased productive power of his labor is not due either to his capital or his labor, nor to the mere application of some natural force separate from capital and labor, but incorporated in the capital. It arises from the greater natural power of production of labor in conjunction with some other natural power, which natural power is not at the command of all capitals in this sphere, whereas such a thing as the elasticity of steam is. The application of this other natural power does not follow as a selfunderstood matter, whenever capital is invested in this sphere. It is a monopolised natural power, which, like a water fall, is only at the command of those who can avail themselves of particular pieces of the globe and its opportunities. It is not within the power of capital to call to life this natural premise for a greater productivity of labor, whereas any capital may transform water into steam. Water power is found only locally in nature, and wherever it does not exist, it cannot be created by any investment of capital. It is not dependent upon products which labor can secure, such as machines, coal, etc. It is dependent upon definite natural conditions of definite portions of the globe. That section of industrial capitalists who own waterfalls excludes the other section who do not own any from the application of this power, because the land, and particularly land supplied with water power, is limited. Of course this does not prevent the quantity of water power available for industrial purposes from being increased, even if the number of natural waterfalls in a certain country is limited. Water power may be artificially diverted, in order to exploit its motive force fully. Under certain conditions a water wheel may be improved so as to use the highest possible amount of water power; in places where the ordinary wheel is not suitable for supplying water, turbines may be used, etc. The possession of this natural power forms a monopoly in the hand of its owner, it is a premise for the increase of the productivity of the invested capital, which cannot be created by the process of production of the capital itself.¹²⁶ This natural power, which can be monopolised in this way, is always attached to the soil. Such a natural power does not

belong to the general conditions of that particular sphere of production, and not to those conditions, which may be made general.

Now let us assume that the waterfalls with the land on which they are found are held in the hands of persons, who are considered the owners of these portions of the globe, who are land owners. These owners may exclude others and prevent them from investing capital in the waterfalls or using waterfalls by means of capital. They can permit such a use or forbid it. The capital cannot create a waterfall out of itself. Therefore the surplus profit, which arises from this employment of waterfall, is not due to capital, but to the harnessing of a natural power, which can be monopolised and has been monopolised, by capital. Under these circumstances the surplus-profit is transformed into ground-rent, that is, it falls into the hands of the owner of the waterfall. If the industrial capitalist pays to the owner of the waterfall 10 pounds sterling annually, then his profit is 15 pounds sterling, that is 15% on the 100 which then make up his cost of production; and he is just as well off, or possibly better, as all other capitalists of his sphere of production, who work with steam. It would not matter, if this capitalist should be the owner of the waterfall. He would in that case pocket the surplus profit of 10 pounds in his capacity as a landowner, not in his capacity as an industrial capitalist, just because this surplus is not due to his capital as such, but to a limited natural power separate from his capital, over which he has command, because he has a monopoly of it. And so it is converted into ground-rent.

It is evident that this is always a differential rent, for it does not enter as a determining factor into the average price of production of commodities, but rather is based on it. It always arises from the difference between the individual price of production of the individual capital having command over monopoly of natural power and the general price of production of the total capital invested in that particular sphere of production.

This ground-rent does not arise from the absolute increase of the productivity of the employed capital, or of the labor appropriated by it, since this can only reduce the value of commodities; it is due to the greater relative fertility of definite individual capitals invested in a certain sphere of production, as compared with investments of capital, which are excluded

from these exceptional and natural conditions favoring the productivity. For instance, if the use of steam should offer overwhelming advantages not attached to the use of water power, or tending to neutralise the benefits to be derived from water power, then, water power would not be used and could not produce any surplus profit, or ground-rent, even though coal has a value and water power has not.

The natural power is not the source of the surplus profit, but only its natural basis, because this natural basis permits an increase in the productive power of labor. In the same way the use-value is the general bearer of the exchange-value, but not its cause. If the same use-value could be created without labor, it would have no exchange-value, yet it would have the same useful effect as ever. On the other hand, nothing can have an exchange-value unless it has a use-value, unless it has this useful bearer of labor. Were it not for the fact that the different values are neutralised into prices of production, and the different individual prices of production into one average price of production regulating the market, the mere increase in the productivity of labor by the use of a waterfall would merely lower the price of the commodities produced with the waterfall, without adding anything to the share of profit contained in those commodities. On the other hand, this increased productivity of labor would not be converted into surplus-value, were it not for the fact that capital appropriates the natural and social productivity of labor as though it were its own.

The private ownership of the waterfall has nothing to do with the creation of that portion of the surplus-value (profit), and of the price of a commodity in general, which is produced by the help of the waterfall. This surplus profit would also exist, if private property did not prevail, for instance, if the land supplied with the waterfall were appropriated by the industrial capitalist as masterless booty. Hence private property in land does not create that portion of value, which is transformed into surplus profit, but it merely enables the landowner, who has possession of the waterfall, to coax this surplus profit out of the pocket of the industrial capitalist into his own. It is the cause, not of the creation of this surplus profit, but of its transformation into ground-rent, of the appropriation of this portion of the profit, or of the price of commodities, by the owner of the land or of the waterfall.

It is evident that the price of the waterfall, that is the price which the owner of it would receive if he were to sell it to some other man, perhaps to the industrial capitalist, would not enter directly into the general price of production of the commodities, although it would enter into the individual cost-price of the industrial capitalist. For the rent arises here from the price of production of the commodities produced by steam machinery, and this price is regulated independently of the waterfall. Furthermore, this price of the waterfall is an irrational expression, behind which a real economic relation is concerned. The waterfall, like the earth in general, and like any natural force, has no value, because it does not represent any materialised labor, and therefore it really has no price, which is normally but the expression of value in money. Where there is no value, it is obvious that it cannot be expressed in money. This price is merely capitalised rent. The ownership of land enables the landowner to catch the difference between the individual profit and the average profit. The profit thus acquired, which is renewed every year, may be capitalised, and then it appears as the price of a natural power itself. If the surplus profit realised by the use of the waterfall amounts to 10 pounds sterling per year, and the average interest is 5%, then these 10 pounds sterling annually represent the interest on a capital of 200 pounds sterling; and this capitalisation of the annual 10 pounds sterling, which the waterfall enables its owner to catch, appears then as the capital-value of the waterfall itself. That it is not the waterfall itself, which has a value, but that its price is a mere reflex of the appropriated surplus profit, which the use of the waterfall yields to the industrial capitalist, capitalistically calculated, becomes at once evident in the fact that the price of 200 pounds sterling represents merely the product of a surplus profit of 10 pounds sterling for 20 years, whereas the same waterfall will enable its owner to catch these 10 pounds sterling every year for 30 years, or 100 years, or an indefinite number of years, so long as circumstances remain the same. On the other hand, if some new method of production, which is not suitable for water power, should reduce the cost price of the commodities produced by steam machinery from 100 to 90 pounds sterling, the surplus profit, and with it the rent, and with it the price of the waterfall, would disappear.

Now that we have explained our general conception of differential rent, we will pass on to its consideration in agriculture, strictly so-called. What applies to it will also apply on the whole to mines.

CHAPTER XXXIX. THE FIRST FORM OF DIFFERENTIAL RENT.

(Differential Rent I.)

RICARDO is quite right when he writes the following sentences:

“Rent is always the difference between the produce obtained by the employment of two equal quantities of capital and labor” (Principles,). [He means differential rent, for he assumes that no other rent but differential rent exists.] He should have added “On the same quantities of land,” so far as ground-rent and not surplus profit in general is concerned.

In other words, surplus profit, if normal and not due to accidental transactions in the process of circulation, is always produced as a difference between the products of two equal quantities of capital and labor. This surplus profit is transformed into ground rent, when two equal quantities of capital and labor are employed on equal quantities of land with unequal results. However, it is by no means absolutely necessary that this surplus profit should arise from unequal results of equal quantities of invested capital. The various investments may also employ unequal quantities of capital. Indeed, this is generally the case. But equal aliquot parts, for instance 100 pounds sterling of each, give unequal results; that is, their rates of profit are different. This is the general prerequisite for the existence of surplus profit in any sphere, where capital is invested. The second prerequisite is the transformation of this surplus profit into ground-rent (and of rent in general as distinguished from profit); it should always be analysed, when, how, under what conditions this transformation takes place.

Ricardo is also right in the following sentence, provided it is limited to differential rent: “Whatever diminishes the inequality in the produce obtained on the same or on new land, tends to lower rent; and whatever increases that inequality, necessarily produces an opposite effect and tends to raise it.” (P. 74.)

However, among these causes are not merely the general ones (fertility and location), but also 1) the distribution of taxes, according to whether it works uniformly or not; it always has the latter effect, for instance in England, when it is not centralised and when the tax is levied on the land, not on the rent; 2) the inequalities arising from the different development of agriculture in different parts of the country, since this line of industry, on account of its traditional character, is more difficult to level than manufacture; 3) the inequality in the distribution of capital among the capitalist tenants. Since the capture of agriculture by the capitalist mode of production, the transformation of independently producing farmers into wage workers, is in fact the last conquest of this mode of production, these inequalities are greater here than in any other line of industry.

After these preliminary remarks I will give a brief summary of the peculiarities of my own analysis as distinguished from that of Ricardo, etc.

We consider first the unequal results of equal quantities of capital, applied to different lands of equal area; or on lands with unequal areas, but calculated on the same aliquot parts of it.

The two general causes of these unequal results independent of capital, are 1) Fertility. (With reference to this first point the analysis should state, what is included in the natural fertility of lands, and what elements enter into it.) 2) The location of the lands. This is a deciding factor in colonies, and in general determines the succession in which lands shall be taken under cultivation. Furthermore it is evident that these two different causes of differential rent, fertility and location, may work in opposite directions. A certain soil may be very favorably located and yet be very poor in fertility, and vice versa. This circumstance is important, for it explains how it is that the work of opening the soil of a certain country to cultivation may equally well proceed from the worse to the better soil, instead of vice versa. Finally it is clear that the progress of social production has on the one hand the general effect of leveling the differences arising from location as a cause of ground-rent, by creating local markets and improving locations by means of facilities for communication and transportation; and that, on the other hand, it increases the differences of the individual locations in a certain district by separating agriculture from manufacture and forming great

centers of production on the one hand while relatively isolating the agricultural districts on the other hand.

For the present, however, we leave this point, location, out of consideration and confine ourselves to natural fertility. Aside from climatic factors, etc., the difference in natural fertility is one of the chemical compositions of the top soil, that is of its different contents in plant nourishment. However, assuming the chemical composition and natural fertility in this respect to be the same for two areas, the actual fertility will be different according to whether these elements of plant nourishment have a form, in which they may be more or less easily assimilated and immediately utilised for nourishing plants. Hence it will depend partly upon the chemical, partly upon the mechanical development of agriculture, to what extent the same natural fertility may be made available in fields of the same natural fertility. Fertility, although an objective quality of the soil, always implies economic relations, a relation to the existing chemical and mechanical development in agriculture, of course it changes with such a development. By dint of chemical applications (such as the use of certain liquid manures to stiff clay loam, or burning of heavy clay soils) or of mechanical appliances (such as special plows for heavy soils) the obstacles may be removed, which made a soil of the same fertility as some other actually less fertile (drainage also belongs under this head). Or even the succession of soils in cultivation may be changed thereby, as was the case, for instance, with light sandy soil and heavy clay soil in a certain period of development of English agriculture. This shows once more that historically, in the succession of soils under cultivation, one may pass just as well from very fertile soils to less fertile ones as vice versa. The same may come to pass by any artificially created improvement in the composition of the soil, or by a mere change in the methods of agriculture. Finally the same result may be brought about by a change in the succession of the predominant kinds of soil, owing to different conditions of the subsoil, as soon as it is likewise taken into cultivation and turned over into top layers. This is caused either by the employment of new methods of agriculture (such as planting of stock feed), or any mechanical appliances, which either turn the subsoil into top layers, or mix it with the top soil, or cultivate the subsoil without throwing it up.

All these influences upon the differential fertility of different lands amount to the practical result that for the economic fertility the state of the productivity of labor, in this case the faculty of agriculture of making the natural fertility of the soil immediately available, a faculty which varies in different periods of development, is as much an element in the so-called natural fertility of the soil as its chemical composition and its other natural qualities.

We assume, then, the existence of a certain stage of development of agriculture. We assume furthermore, that the predominant succession of soils is calculated with reference to this stage of development, a thing which is, of course, always the case with simultaneous investments of capital on the different soils. Under such circumstances differential rent may form either in an ascending or a descending succession, for although the succession is an established fact for the totality of the actually cultivated lands, a movement of succession leading to this formation always preceded it.

Let us assume the existence of four kinds of soil, A, B, C, D. Let us furthermore assume that the price of one-quarter of wheat is three pounds sterling, or 60 shillings. Since rent is here merely a differential rent, this price of 60 shillings per quarter for the worst soil is equal to the cost of production, that is equal to the capital plus the average profit.

Let A be this worst soil and yield for each 50 shillings of expenditure one-quarter of wheat worth 60 shillings, so that the profit is 10 shillings, or 20%.

Let B yield for the same expenditure 2 quarters of wheat, or 120 shillings. This would be 70 shillings of profit, or a surplus profit of 60 shillings.

Let C yield for the same expenditure 3 quarters, or 180 shillings; total profit 130 shillings, surplus profit 120 shillings.

Let D yield 4 quarters, 240 shillings, 190 shillings of profit, 180 shillings of surplus profit.

Then we shall have the following succession:
lf0445-03-0764-t0001.gif

The respective rents are: $D = 190 \text{ sh.} - 10 \text{ sh.}$, or the difference between D and A; $C = 130 - 10 \text{ sh.}$, or the difference between C and A; $B = 70 - 10 \text{ sh.}$, or the difference between B and A; and the total rent for B, C, D equals 6 quarters, or 360 shillings, equal to the sum of the differences between D and A, C and A, B and A.

This succession representing a certain product in a certain condition may, abstractly considered, descend from D to A, from very fertile to less and less fertile soil, or rise from A to D, from relatively poor to more and more fertile soil, or may fluctuate in a now rising, now descending curve, for instance from D to C, from C to A, from A to B (and we have already mentioned the reasons why this might take place in reality).

The process leading to the descending succession took place in the following manner: The price of one-quarter of wheat rose gradually from, say, 15 shillings to 60 shillings. As soon as the 4 quarters produced by D (assume them to have been so many million quarters) did not suffice any more, the price of wheat rose to a point where the missing supply could be raised by C. That is to say, the price of wheat must have risen to 20 shillings per quarter. When it had risen to 30 shillings per quarter, B could be taken under cultivation, and when it reached 60 shillings per quarter, A could be taken in, and the capital invested in it did not have to be content with a lower rate of profit than 20%. In this way a rent was formed for D, first of 5 shillings per quarter, or 20 shillings for the 4 quarters produced by it; then of 15 shillings per quarter, or 60 shillings, then of 45 shillings per quarter, or a total of 180 shillings for 4 quarters.

If the rate of profit of D originally was likewise 20%, then its total profit on 4 quarters of wheat was also but 10 shillings, but this stood for more grain when the price was 15 shillings than it does when the price is 60 shillings. But since the grain enters into the reproduction of labor-power, and a portion of each quarter has to make good some wages and another some constant capital, the surplus-value under this condition was higher,

and to that extent, other things being the same, the rate of profit. (The matter of the rate of profit will have to be analysed separately and in detail.)

On the other hand, if the succession went the opposite way, that is, if the movement started from A, then the price of wheat at first rose above 60 shillings, when new land had to be taken under cultivation. But when the necessary supply was raised by B, a supply of 2 quarters, the price fell once more to 60 shillings. B raised wheat at a cost of 30 shillings per quarter, but sold it at 60 shillings, because its supply sufficed just to cover the demand. In this way a rent was formed, first of 60 shillings for B, and in the same way for C and D; always assuming that the market price remained at 60 shillings, although C and D relatively raised wheat having a value of 20 and 15 shillings respectively, because the supply of the one-quarter raised by A was as much needed as ever to satisfy the total demand. In this case the rising of the demand above the supply first raised by A, then by A and B, would not have made it possible to cultivate successively B, C and D, but would merely have caused a general extension of the sphere of cultivation, by which the more fertile lands came under its control later.

In the first succession, an increase in the price would raise the rent and lower the rate of profit. The lowering of the rate of profit might be entirely or partially checked by opposing circumstances. This point will have to be treated later. It should not be forgotten, that the general rate of profit is not determined uniformly in all spheres of production by the surplus-value. It is not the agricultural profit, which determines the industrial profit, but vice versa. But of this more anon.

In the second succession the rate of profit on the invested capital would remain the same. The mass of profit would present itself in less grain; but the relative price of grain, compared with that of other commodities, would have risen. Only, whatever increase there might be in the profit, would separate itself from the actual profit in the form of rent, instead of flowing into the pockets of the capitalist tenant and appearing as a growing profit. The price of grain, however, would remain unchanged under the conditions assumed here.

The development and growth of differential rent would remain the same, both with unaltered and with increasing prices, and with a continued progress from worse to better land as well as with a continued regression from better to worse land.

So far we have assumed 1) that the price rises in the one succession and remains stationary in the other; 2) that there is a continual progression from better to worse soil, or from worse to better soil.

But now let us assume that the demand for grain rises from its original figure of 10 to 17 quarters; furthermore, that the worst soil A is displaced by another soil A', which raises $1\frac{1}{3}$ quarters at a price of production of 60 shillings (50 sh. cost plus 10 sh. for 20% profit), so that its price of production for one-quarter is 45 shillings; or, perhaps, the old soil A may have become improved through a continued rational cultivation, or may be cultivated more productively at the same cost, for instance, by the introduction of clover, etc., so that its product with the same investment of capital rises to $1\frac{1}{3}$ quarters. Let us also assume that the classes B, C and D of soil supply the same product as ever, but that new classes of soil have been introduced, for instance, A' of a fertility between A and B, furthermore B' and B'' of a fertility between B and C. In that case we should witness the following phenomena:

The price of production of one-quarter of wheat, or its regulating market price, would have fallen from 60 shillings to 45 shillings, or by 25%.

The cultivation would have proceeded simultaneously from more fertile to less fertile soil, and from less fertile to more fertile soil. The soil A' is more fertile than A, but less fertile than the hitherto cultivated soils B, C and D. And B' and B'' are more fertile than A, A' and B, but less fertile than C and D. The succession would thus have proceeded in crisscross fashion. Cultivation would not have proceeded to soil absolutely less fertile than A, etc., but it would have proceeded to relatively less fertile than the soils C and D; on the other hand, cultivation would not have taken up soil absolutely more fertile, but at least relatively more fertile compared to the hitherto least fertile soils A or A and B.

The rent on B would have fallen; likewise the rent on C and D; but the total rental would have risen from 6 quarters to $7 \frac{2}{3}$; the mass of the cultivated and rent paying lands would have increased, and the mass of the product would have risen from 10 quarters to 17. The profit, if remaining the same for A, expressed in grain, would have risen; but the rate of profit itself might have risen, because the relative surplus-value did. In this case the wages, and with them the investment of variable capital, and with it the total investment, would have been reduced on account of the cheapening of the means of subsistence. The total rental would have fallen from 360 shillings to 345 shillings.

Let us draw up the new succession.

lf0445-03-0768-t0001.gif

Finally, if only the classes of soil A, B, C and D were cultivated, but their productivity raised in such a way that A would produce 2 quarters instead of 1, B, 4 quarters instead of 2, C, 7 quarters instead of 3, and D, 10 quarters instead of 4, so that the same causes would have acted differently upon the various classes of soil, the total production would have increased from 10 quarters to 23. Assuming that the demand would absorb these 23 quarters by an increase of the population and the falling of prices, we should get the following table:

lf0445-03-0768-t0002.gif

The numbers in this and in other tables are arbitrarily chosen, but the assumptions are quite rational.

The first and principal assumption is that the improvement in agriculture acts differently upon different soils, and in this case more so upon the best classes of soil, C and D, than upon the A and B classes. Experience has shown that this is indeed the case, although the opposite may also take place. If the improvement should affect the lesser soils more than the better ones, the rent on these last ones would have fallen instead of rising.

But in our table we have assumed that the absolute growth of the fertility of all classes of soil is simultaneously accompanied by an increase of the higher relative fertility of the better classes of soil, C and D, which implies

an increasing difference between the various products with the same investment of capital, and thus an increase of the differential rent.

The second assumption is that the total demand must keep step with the increase of the total product. In the first place, one need not imagine such an improvement to come abruptly, but gradually, until the succession in table III is reached. In the second place, it is a mistake to say that the consumption of necessities of life does not grow with their cheapening. The abolition of the corn laws in England proved the reverse (see Newman), and the contrary view is derived merely from the fact that great and sudden differences in the harvests, caused by the weather, bring about at one time an extraordinary fall, at another an extraordinary rise in the prices of cereals. While in such a case the sudden and short cheapness does not get time to exert its full effect upon the extension of consumption, the opposite takes place when the cheapening process arises out of the lowering of the regulating price of production itself and has permanency. In the third place, a portion of the grain may be consumed in the shape of whiskey or beer. And the rising consumption of these articles is by no means confined within narrow limits. In the fourth place, this matter depends partly upon the increase of the population, and for the other part the country may be a grain exporting one, as England was far beyond the middle of the 18th century, so that the demand is not regulated by the boundaries of a mere national consumption. Finally the increase and cheapening of the wheat production may have the result of making wheat instead of rye or oats the principal article of consumption for the masses, so that the demand for it may grow for this reason alone, just as the opposite may take place when the product decreases and prices rise. — Under these assumptions, and with the figures previously chosen, succession No. III would show a fall in the price per quarter from 60 shillings to 30, that is 50%, that production compared to succession No. I would increase from 10 quarters to 23, in other words, by 130%; that the rent would remain stationary upon the soil B, be doubled upon C, and more than doubled upon D, and that the total rental would increase from 18 pounds sterling to 22, a growth of $22\frac{1}{9}\%$.

A comparison of these three tables (taking table I twice, one rising from A to D, and one descending from D to A), which may be considered either as existing gradations under some definite stage of society, for instance, as

existing side by side in three different countries, or as succeeding one another in different periods of development in the same country, would show:

That the succession, when complete, whatever may have been the course of its formative process, always has the appearance of being in a descending line; for in studying the rent, the point of departure will always be the soil producing the maximum of rent, and the closing point will be the soil yielding no rent.

That the price of production of the worst soil, which yields no rent, is always the regulating market price, although this market price in table I, if its succession was formed in an ascending line, could not remain stationary, unless better and better soil were cultivated. In that case the price of the grain produced on the best soil is a regulating one to the extent that it depends upon the quantity produced on such soil in what measure the soil of class A shall remain the regulator. For instance, if B, C, D should produce more than the demand calls for, then A would cease to be the regulator. This is what Storch has in mind, when he adopts the best class of soil as the regulating one. In this manner the American price of cereals regulates the English price.

Differential rent arises from the differences in the natural fertility of the soil which depends upon the prevailing degree of development of cultivation (leaving aside for the present the question of location), in other words, from the limited area of the best lands, and from the circumstance that equal capitals must be invested in unequal soils, which yield unequal products with the same capital.

The existence of differential rent and of a graduated succession of differential rents may be due quite as much to a descending succession, which leads from the better to the worse soils, as to an ascending one, which takes the opposite direction. Or it may be brought about by alternating forward and backward movements. (Succession No. II may form by a process from D to A, or from A to D; succession No. II comprises both movements.)

According to its mode of formation, differential rent may develop with a stationary, rising or falling price of the products of the soil. With a falling price the total production and the total rental may rise, and rent may form on hitherto rentless lands, even though the worst soil A may have been displaced by a better one, or may itself have become improved, and although the rent may decrease on other better, or even the best, lands (table II); this process may also be accompanied by a fall of the total rent (in money). Finally, when prices are falling on account of a general improvement of cultivation, so that the product and the price of the product of the worst soils decrease, the rent may remain the same or may fall on a part of the better soils, but rise on the best soils. It is true that the differential rent of every soil, compared with the worst soil, depends upon the price, say, of the quarter of wheat, when the difference of the quantity of products is given. But when the price is given, differential rent depends upon the magnitude of the differences of the quantity of products, and if, with an increasing absolute fertility of all soils that of the better soil grows relatively more than that of the worse soil, the magnitude of this difference grows to that extent. In this way (see Table I), when the price is 60 shillings, the rent of D is determined by its differential product as compared to A, in other words, by its surplus of 3 quarters. The rent is therefore three times sixty, or 180 shillings. But in Table III, in which the price is 30 shillings, the rent is determined by the quantity of the surplus product of D as compared to A, that is 8 quarters, and therefore it is eight times thirty, or 240 shillings.

This does away with the primitive misconception of differential rent still found among men like West, Malthus, Ricardo, to the effect that it necessarily requires a progress toward worse and worse soil, or an ever decreasing productivity of agriculture. It rather may exist, as we have seen, with a progress to a better and better soil; it may exist when a better soil takes the lowest position formerly occupied by the worst soil; it may be accompanied with a progressive improvement of agriculture. Its premise is merely the inequality of the different kinds of soil. So far as the development of productivity is concerned, it implies that the increase of absolute fertility of the total area does not do away with this inequality, but either increases it, or leaves it unchanged, or merely reduces it somewhat.

From the beginning to the middle of the 18th century England's cereal prices fell continually in spite of the falling prices of gold and silver, while at the same time (viewing this entire period) there was an increase of rent, of the rental, of the area of the cultivated lands, of agricultural production, and of the population. This corresponds to Table I combined with Table II in an ascending line, but in such a way that the worst land A is either improved or eliminated from the grain area; this does not imply that it was not used for other agricultural or industrial purposes.

From the beginning of the 19th century (the date should be given more precisely) until 1815 there is a continual rise in the cereal prices, accompanied by a steady growth of the rent, of the rental, of the volume of the cultivated lands, of agricultural production, and of the population. This corresponds to Table I in a descending line. (Quote here some passages on the cultivation of inferior lands in those times.)

In Petty's and Davenant's time, the farmers and land owners complain about the improvements and the breaking of new ground; the rent on the superior soils falls, the total rental increases through the extension of the soils yielding rent.

(These three points should be illustrated later on by quotations; likewise the difference in the fertility of the different cultivated portions of the soil in a certain country.)

The general rule in differential rent is that the market-value always stands above the total price of production of the mass of products. For instance, take Table I. The ten quarters of the total product are sold at 600 shillings, because the market price is determined by the price of production of A, which amounts to 60 shillings per quarter. But the actual price of production is:

A 1 qr. = 60 sh. 1 qr. = 60 sh. B 2 qrs. = 60 sh. 1 qr. = 30 sh. C 3 qrs. = 60 sh. 1 qr. = 20 sh. D 4 qrs. = 60 sh. 1 qr. = 15 sh. 10 qrs. = 240 sh. Average 1 qr. = 24 sh.

The actual price of production of these 10 quarters is 240 shillings. But they are sold at 600 shillings, 250% too dear. The actual average price for 1

quarter is 24 shillings; the market price is 60 shillings, also 250% too dear.

This is a determination by the market-value, which is enforced on the basis of capitalist production by means of competition; it creates a false social value. This arises from the law of the market-value, to which the products of the soil are subject. The determination of the market-value of the products, including the products of the soil, is a social act, although performed by society unconsciously and unintentionally. It rests necessarily upon the exchange-value of the product, not upon the soil and its differences in fertility.

If we imagine that the capitalistic form of society is abolished and society is organized as a conscious and systematic association, then those 10 quarters represent a quantity of independent labor, which is equal to that contained in 240 shillings. In that case society would not buy this product of the soil at two and a half times the labor time contained in it. The basis of a class of land owners would thus be destroyed. This would have the same effect as a cheapening of the product to the same amount by foreign imports. While it is correct to say that, by retaining the present mode of production but paying the differential rent to the state, the prices of the products of the soil would remain the same, other circumstances remaining unchanged, it is wrong to say that the value of the products would remain the same, if capitalist production were superseded by association. The sameness of the market prices for commodities of the same kind is the way in which the social character of value asserts itself on the basis of capitalist production, as it does of any production resting on the exchange of commodities between individuals. What society in its capacity as a consumer pays too much for the products of the soil, what constitutes a minus for the realisation of its labor time in agricultural production, is now a plus for a portion of society, for the landlords.

A second circumstance, important for the analysis to be given under II in the next chapter, is the following:

It is not merely a question of the rent per acre, or per hectare, nor in general of a difference between the price of production and the market price, nor between the individual and general price of production per acre,

but it is also a question of how many acres of each class of soil are under cultivation. The point of importance is here primarily the magnitude of the rental, that is, of the total rent of the entire cultivated area; but it serves us at the same time as a transition to the development of a rise in the rate of the rent, although there is neither a rise in the prices, nor an increase in the differences of the relative fertility of the various kinds of soil when prices are falling.

We had above:

lf0445-03-0774-t0001.gif

Now let us assume that the number of cultivated acres is doubled in every class. Then we have:

lf0445-03-0775-t0001.gif

Let us assume two other cases, and let the first be one, in which production expands on the two inferior classes of soil, in the following manner:

lf0445-03-0775-t0002.gif

Finally let us assume an unequal expansion of production and of the cultivated area on all four classes, in the following manner:

lf0445-03-0775-t0003.gif

In the first place, the rent per acre remains the same in all these four cases I, I a, I b and I c. For in fact the result of the same investment of capital per acre of the same class of soil has remained unchanged. Nothing more has been assumed than a fact which may be observed in any country at any given moment, namely that the various classes of soil participate in certain definite proportions in the entire cultivated area. And furthermore, a fact which may be observed in any two countries that are compared, or in the same country at different periods of time, namely that the proportion varies in which the cultivated area is distributed among these classes.

If we compare Ia with I, then we see, if the cultivation of the soils of all four classes grows in the same proportion, that a doubling of the cultivated

acres doubles the total production, and at the same time doubles the rent in grain and money.

If we compare Ib and Ic successively with I, we see that in both cases a triplication of the area subject to cultivation takes place. It rises in both cases from 4 acres to 12, but in Ib it is the classes A and B which get the greatest share of the increase, although A pays no rent, and B yields the smallest differential rent. But of 8 newly cultivated acres A and B get 3 each, or 6 between the two of them, whereas C and D get only 1 acre each, or together 2 acres. In other words, three-quarters of the increase go to A and B, and only one-quarter to C and D. According to this assumption and comparing Ib with I, the trebled area of cultivation does not result in a trebled product, for the product does not increase from 10 to 30, but only to 26. On the other hand, seeing that a considerable portion of the increase takes place on A, which does not yield any rent, and since the principal portion of the remaining increase takes place on B, the rent in grain rises only from 6 quarters to 14, and the rent in money from 18 pounds sterling to 42.

But if we compare Ic with I, where the soil yielding no rent does not increase in area, and the soil yielding a minimum rent increases but slightly, while the principal portion of the increase takes place on C and D, we find that the trebled area results in an increase of production from 10 quarters to 36, more than three times the quantity. The rent in grain has risen from 6 quarters to 24, or quadrupled; and so has the money rent from 18 pounds sterling to 72.

In all these cases the price of the agricultural product naturally remains stationary. The total rental increases in all cases with the extension of cultivation, unless it takes place exclusively on the worst soil, which does not pay any rent. But the growth is unequal. In proportion as the extension of cultivation takes place upon the superior classes of soil and consequently the quantity of the products grows not merely at the ratio of expansion of the area, but even faster, the rent in grain and money increases. In proportion as the worst soil and the class next above it share principally in the expansion of the area (provided that the worst soil represents a constant class), the total rental does not rise in proportion to the extension of

cultivation. If there are two countries, in which the class A, that yields no rent, is of the same nature, the rental stands in the reverse ratio to the aliquot part represented by the worst soil and the lesser classes next above it in the total area of the cultivated soil, and therefore in the reverse ratio to the quantity of the products of equal investments of capital on the same total areas of land. The proportion between the quantity of the worst cultivated soil and that of the better soil, within the total cultivated area of a certain country, thus has the opposite effect upon the total rental than the proportion between the quality of the worst cultivated soil and that of the better soil has upon the rent per acre and, other circumstances remaining the same, upon the total rental. The confounding these two things has given rise to many mistaken objections to differential rent.

The total rental, then, increases by the mere extension of the cultivation, and by the consequent greater investment of capital and labor in the soil.

But the most important point is this: Although it is our assumption that the proportion of the rents upon the various classes of soil remains the same, calculated per acre, and therefore also the rate of rent considered with reference to the capital invested in each acre, yet we must observe the following: If we compare Ia with I, the case in which the number of cultivated acres and the capital invested in them have been proportionately increased, we find that just as the total production has increased proportionately to the expanded agricultural area, that is just as both of them have been doubled, so has the rental. It has risen from 18 pounds sterling to 36, just as the number of acres has risen from 4 to 8.

If we take the total area of 4 acres, we find that the total rental amounted to 18 pounds sterling, or the average rent, including the soil which does not pay any rent, $4\frac{1}{2}$ pounds sterling. This calculation might be made, say, by a landlord owning all 4 acres. And in this way the average rent is statistically calculated upon a whole country. The total rental of 18 pounds sterling is secured by the investment of a capital of 10 pounds sterling. We call the ratio of these two figures the rate of rent; in the present case it is 180%.

The same rate of rent follows in Ia, where 8 instead of 4 acres are cultivated, but all classes of land have shared in the same proportion in the

increase. The total rental of 36 pounds sterling gives for 8 acres and an invested capital of 20 pounds sterling an average rent of $4\frac{1}{2}$ pounds sterling per acre and a rate of rent of 180%.

But if we consider Ib, in which the increase has taken place mainly upon the two inferior classes of soil, we find there a rent of 42 pounds sterling upon 12 acres, or an average rent of $3\frac{1}{2}$ pounds sterling per acre. The invested total capital is 30 pounds sterling, and the rate of rent 140%. The average rent per acre has decreased by one pound sterling, and the rate of rent has fallen from 180 to 140%. Here then we have an increase of the total rental from 18 pounds sterling to 42, and yet a fall of the average rent, calculated both per acre and per capital, while production grows also, but not proportionately. This takes place, although the rent upon all classes of soil, both per acre and per capital, remains the same. It does so, because three-quarters of the increase go to the class A, which does not pay any rent, and upon class B, which pays only the minimum rent.

If the total extension in the case Ib had taken place only upon the soil A, then we should have 9 acres upon A, 1 acre upon B, 1 acre upon C and 1 acre upon D. The total rental would be 18 pounds sterling, the same as before, the average rent upon the 12 acres would be $1\frac{1}{2}$ p. st. per acre; and a rent of 18 pounds sterling on an invested capital of 30 pounds sterling would give a rate of rent of 60%. The average rent, both per acre and per invested capital, would have decreased, and the total rental would not have increased.

Finally, let us compare Ic with I and Ib. Compared to I, the area has been trebled, also the invested capital. The total rental is 72 pounds sterling upon 12 acres, or 6 pounds sterling per acre against $4\frac{1}{2}$ pounds sterling in case I. The rate of rent upon the invested capital (72: 30 pounds sterling) is 240% instead of 180%. The total product has risen from 10 quarters to 36.

Compared to Ib, where the total area of the cultivated acres, the invested capital, and the difference between the cultivated classes are the same, but the distribution different, the product is 36 quarters instead of 26, the average rent per acre is 6 pounds sterling instead of $3\frac{1}{2}$, and the rate of rent with reference to the same invested total capital is 240% instead of 140%.

No matter whether we regard the various conditions in Tables Ia, Ib and Ic as existing side by side in different countries, or as existing successively in the same country, we come to the following conclusions: so long as we have the conditions mentioned hereafter, that is, so long as the price of cereals remains unchanged, because the worst rentless soil has the same product; so long as the differences in the productivity of the different cultivated soils remain the same; so long as the respective products of the same invested capitals are the same for aliquot parts (acres) of the areas cultivated in every class of soil; so long as the ratio between the rents per acre of each class of soils and with the same rate of rent upon the capital invested in each portion of the same kind of soil is constant: 1) the rental always increases with the extension of the cultivated area and with the consequent increased investment of capital, with the exception of the case in which the entire increase falls on the rentless soil. 2) Both the average rent per acre (total rental divided by the total number of acres) and the average rate of rent (total rental divided by the invested total capital) may vary very considerably; both of them in the same direction, but in different proportions compared to one another. If we leave out of consideration the case, in which the increase takes place upon the rentless soil, we find that the average rent per acre and the average rate of rent upon the capital invested in agriculture depend upon the proportional shares, which the various classes of soil claim in the cultivated area; or, what amounts to the same, upon the distribution of the employed total capital among the classes of soil of different fertility. Whether much or little land is cultivated, and whether the total rental is therefore larger or smaller (with the exception of the case, in which the increase is confined to A) the average rent per acre, or the average rent per invested capital, remains the same so long as the proportions of the participation of the various classes of soil in the total cultivated area remain unchanged. In spite of the rise, even of a very considerable one, in the total rental with the extension of cultivation and the expansion of the invested capital, the average rent per acre and the average rent per capital fall whenever the extension of the rentless lands, or of the lands of inferior fertility, increases more than that of the superior rent paying ones. On the other hand the average rent per acre and the average rent per capital increase in proportion as the better lands constitute a greater

part of the total area and employ a relatively greater share of the invested capital.

Hence, if we consider the average rent per acre, or hectare, of the total cultivated soil, in the way that is generally done in statistical works, by comparing either different countries at different epochs, or different epochs in the same country, we find that the average level of the rent per acre, and consequently the total rental, corresponds in certain proportions (although by no means equal ones, but rather more rapidly moving ones) to the absolute, not to the relative, productivity of agriculture in a certain country, that is, to the mass of products brought forth by it on an average upon the same area. For the larger the share taken by the superior soils in the total cultivated area, the greater is the mass of products brought forth by equal investments of capital upon equally large areas of land. And the higher is the average rent per acre. In the opposite case the reverse takes place. In this way the rent does not seem to be determined by the ratios of differential fertility, but of absolute fertility, and the law of differential rent seems thereby abolished. For this reason certain phenomena are disputed, or perhaps they are explained by non-existing differences in the average prices of cereals and in the differential fertility of the cultivated lands, whereas such phenomena are merely due to the fact that the ratio of the total rental, either to the total area of the cultivated soil, or to the total capital invested in this soil, so long as the fertility of the rentless soil remains the same and with it the price of production, and so long as the differences of the various classes of soil remain unchanged, is determined not merely by the rent per acre or the rate of rent per capital, but quite as much by the proportional number of acres of each class of soil in the total number of cultivated acres; or, what amounts to the same, by the distribution of the invested total capital among the various classes of land. Curiously enough this fact has been completely overlooked so far. At any rate we see (and this is important for the progress of our analysis), that the relative level of the average rent per acre, and the average rate of rent (or the ratio of the total rental to the total capital invested in the soil), may rise or fall, through the mere extensive expansion of cultivation, while prices remain the same, the differential fertilities of the various soils remain unaltered, and the rent per acre is constant, or while the rate of rent for the capital invested per acre in

every actual rent paying class of soil, or for every rent paying capital, remains unchanged.

We have to make the following additional remarks with reference to the form I of the differential rent, which also apply partly to form II:

We have seen that the average rent per acre, or the average rate of rent per capital, may rise with an extension of cultivation, with stationary prices, and unaltered differential fertilities of the cultivated lands. As soon as all the land in a certain country has been appropriated, while the investment of capital in land, the cultivation of the soil, and the population, have reached a certain level — all of which conditions are matters of fact as soon as the capitalist mode of production becomes the prevailing one and invades also agriculture — the price of the uncultivated soil of various classes (assuming differential rent to exist) is determined by the price of the cultivated lands of the same quality and equivalent location. The price is the same — after deducting the cost of breaking the ground — although this soil does not carry any rent. The price of the land is, indeed, nothing but the capitalised rent. But even in the case of cultivated lands their price pays only future rents, as for instance, when the regulating rate of interest is 5% and the rent for twenty years is paid in advance at one time. When land is sold, it is sold as a rent paying land, and the prospective character of the rent (which is here considered as a fruit of the soil, which it is only seemingly) does not distinguish the uncultivated from the cultivated soil. The price of the uncultivated lands, like their rent, which it represents as though it were its contracted formula, is quite illusory, so long as the land is not actually used. But it is thus determined beforehand and realised as soon as a purchaser is found. Hence, while the actual average rent of a certain land is determined by its real average rental per year and by its proportion to the entire cultivated area, the price of the uncultivated portions of land is determined by that of the cultivated land, and is therefore but a reflex of the capital invested in cultivated land and of the results obtained by such investments. Since all lands with the exception of the worst carry rent (and this rent, as we shall see under the head of differential rent II, rises with the mass of the capital and the corresponding intensity of cultivation), the nominal price of the uncultivated portions of the soil is thus formed, and thus they become commodities, a source of wealth for their owners. This explains at the same

time, why the price of land increases in the whole region, even in the uncultivated part (Opdyke). The speculation in land, for instance in the United States, rests merely upon this reflex, which capital and labor throw on the uncultivated land.

The advance in the extension of the cultivated soil in general takes place either toward inferior soil, or upon the various existing soils in different proportions according to the way in which they present themselves. The step toward inferior soil naturally is never made voluntarily, but cannot be due to anything but to rising prices (assuming the capitalist mode of production to be a fact), and under any mode of production it will be a result of necessity. However, this is not absolutely so. An inferior soil is preferred to a relatively better soil on account of its location, which decides the point during all extension of cultivation in new countries; furthermore for the reason that, while the formation of the soil in a certain region may belong to the superior ones, the better will nevertheless be relieved here and there by inferior soil, so that the inferior soil must be cultivated along with the superior on account of its location. If inferior soil is surrounded by superior soil, then the better soil gives to the poorer soil the advantage of location as against other and more fertile soil, which is not connected with the already cultivated soil, or with soil about to be cultivated.

In this way the state of Michigan was one of the first to export corn. Yet its soil is on the whole poor. But its vicinity to the state of New York and its water routes by lakes and by the Erie Canal gave to it the advantage before the naturally more fertile states which were farther west. The example of this state, as compared to the state of New York, shows us also the transition from superior to inferior soil. The soil of the state of New York, particularly the western portion of it, is far more fertile, particularly in the raising of wheat. This fertile soil was made sterile by robbing it, and now the soil of Michigan appeared as the more fertile.

“In 1836 wheat flour was shipped from Buffalo to the West, principally from the wheat belt of New York and Canada. At present, only 12 years later, enormous supplies of wheat and flour are brought from the West, by way of Lake Erie, and shipped East upon the Erie Canal, in Buffalo and the neighboring port of Blackrock. The export of wheat and flour was

particularly stimulated by the European famine in 1847. The wheat in western New York thus became cheaper, and the raising of wheat less profitable; this caused the New York farmers to throw themselves more upon cattle raising and dairying, fruit growing, etc., lines in which the Northwest, in their opinion, will be unable to compete with them directly.” (J. W. Johnston, Notes on North America, London, 1851, I, .)

It is a mistaken assumption that the land in colonies, and in new countries generally, which can export cereals at cheaper prices, must for that reason be necessarily of a greater natural fertility. The cereals are not only sold below their value in such cases, but below their price of production, namely below the price of production determined by the rate of profit in the older countries.

The fact that we, as Johnston says “are accustomed to connect with these new states, which ship annually such large supplies of wheat to Buffalo, the idea of great natural fertility and endless stretches of rich soil,” depends primarily upon economic conditions. The entire population of such a country, for instance of Michigan, is at first almost exclusively engaged in agriculture, and particularly in producing agricultural goods in large masses, which they can alone exchange for products of industry and tropical goods. The whole surplus product of this population appears, therefore, in the shape of cereals. This distinguishes from the outset the colonial states founded on the basis of the modern world market from those of former, particularly of antique, times. They receive from the world market finished products, which they would have to make themselves under different circumstances, such as clothing, tools, etc. Only on such a basis were the southern states of the Union enabled to make of cotton their staple product. The division of labor upon the world market permitted this. Hence, if they seem to produce a large surplus product in spite of their youth and small relative population, it is not due to the fertility of their soil, nor to the productivity of their labor, but to the onesided form of their labor, and therefore of the surplus product, in which this labor is incorporated.

Furthermore, a relatively inferior soil, which is newly cultivated and was never touched by civilisation before, has accumulated much easily soluble plant food, at least in its upper layers, provided the climatic conditions are

not extremely hard, so that it will yield crops without any manure for a long time, even with very superficial cultivation. The western prairies have the additional advantage of requiring hardly any expenses for clearing, since nature has cleared them herself.¹²⁷ In less fertile districts of this kind a surplus is produced, not through the great fertility of the soil or the yield per acre, but through the large number of acres, which may be superficially cultivated, because this soil costs the cultivator little or nothing compared with older countries. For instance, where share farming exists, as it does in certain parts of New York, Michigan, Canada, etc., there this condition is found. A family cultivates superficially, say, 100 acres, and although the product per acre is not large, the product of 100 acres yields a considerable surplus for sale. In addition to this cattle may be kept on natural pastures for almost nothing, without any artificial grass meadows. It is the quantity, not the quality of the soil, which decides the point here. The possibility of this superficial cultivation is naturally more or less rapidly exhausted, in a reverse ratio to the fertility of the new soil, and in a direct ratio to the export of its products. “And yet such a country will yield excellent harvests, even of wheat; whoever skims the first cream off the soil, will be able to ship an abundant surplus of wheat to the market” (L. c.,). In countries of older civilisation the property relations, the determination of the price of the uncultivated soil by that of the cultivated, etc., make such an extensive economy impossible.

That this soil does not have to be very rich, as Ricardo imagines, nor soils of equal fertility have to be cultivated, may be seen from the following: In the state of Michigan 465,900 acres were planted in 1848 with wheat and produced 4,739,300 bushels, or an average of $10 \frac{1}{5}$ bushels per acre; deducting the seed grain this leaves less than 9 bushels per acre. Of the 29 counties of this state 2 produced an average of 7 bushels, 3 an average of 8 bushels, 2 one of 9, 7 one of 10, 6 one of 11, 3 one of 12, 4 one of 13 bushels, and only one county produced an average of 16 bushels, and another of 18 bushels per acre (L. c.,).

In practical agriculture a higher fertility of the soil coincides with a greater immediate utilisation of this fertility. This may be greater in a naturally poor soil than in a naturally rich one; but it is the kind of soil which a colonist will take up first, and must take up from lack of capital.

The extension of cultivation to greater areas — aside from the case just mentioned, in which recourse must be had to inferior soil than that hitherto cultivated — upon the various classes of soil from A to D, for instance, the cultivation of larger tracts of B and C, does not presuppose by any means a previous rise of the prices of cereals, any more than the annually increasing expansion, for instance of cotton spinning, presupposes a continual rise in the price of yarn. Although a considerable rise or fall of market prices affects the volume of production, nevertheless, aside from this, that relative overproduction which is in itself identical with accumulation always takes place even with average prices, whose stand has neither a paralysing nor an exceptionally stimulating effect upon production. This takes place in agriculture as well as in all other capitalistically managed lines of production. Under different modes of production, this relative overproduction is effected directly by the increase of population, and in colonies by continual immigration. The demand increases constantly, and in anticipation of this new capital is continually invested in new land, although the products of this land will vary according to circumstances. It is the formation of new capitals, which in itself brings this about. But so far as the individual capitalist is concerned, he measures the volume of his production by that of his available capital, to the extent that he himself can still superintend it. What he aims at is to occupy as much room as possible on the market. If there is any overproduction, he does not blame himself, but his competitors. The individual capitalist may expand his production by appropriating a larger aliquot share of the existing market, or by expanding the market itself.

CHAPTER XL. THE SECOND FORM OF DIFFERENTIAL RENT.

(Differential Rent II.)

So far we have considered differential rent only as the result of the different productivity of different investments of capital upon equal areas of land with different fertilities, so that the differential rent was determined by the difference between the yield of the capital invested in the worst, rentless, soil and that of the capital invested in the superior soils, Here we had the invested capitals side by side upon different areas of land, so that every new investment of capital signified a more extensive cultivation of the soil, an expansion of the cultivated area. But in the last analysis the differential rent was by its nature merely the result of the different productivity of equal capitals invested in land.

But could it make any difference, perhaps, whether masses of capital of different productivities are invested successively on the same piece of land, or side by side on different pieces of land, provided that the results are the same?

In the first place, it cannot be denied that it is immaterial, so far as the formation of surplus profit is concerned, whether 3 pounds sterling of cost of production are invested in one acre of A and yield one-quarter of wheat, so that 3 pounds sterling are the price of production and regulating market price of 1 quarter, while 3 pounds sterling of cost of production applied to one acre of B give 2 quarters, and with them a surplus profit of 3 pounds sterling, while in the same way 3 pounds sterling of cost of production applied to one acre of C give 3 quarters and 6 pounds sterling of surplus profit, and finally 3 pounds sterling of cost of production applied to one acre of D give 4 quarters and 9 pounds sterling of surplus profit; or whether the same result is accomplished by applying these 12 pounds sterling of cost of production, or 10 pounds sterling of capital, with the same results and in the same succession upon one and the same acre. It is in either case a capital of 10 pounds sterling, a part of whose successively invested shares of a

value of 2½ pounds sterling each, whether invested in four acres of different fertility side by side, or successively upon one and the same acre, does not yield any surplus profit on account of their different products, whereas the other parts yield a surplus profit in proportion to the difference of their yield from that of the rentless investment.

The surplus profits and the various rates of surplus profit for different parts of the value of capital are formed in the same way in either case. And the rent is nothing but a form of this surplus profit, which constitutes its substance. But at any rate, there are some difficulties in this second method in the way of the transformation of surplus profit into rent, of this change of form, which implies the transfer of the surplus profit from the capitalist tenant to the owner of the land. This accounts for the obstinate resistance of the English tenants to an official statistics of agriculture. It accounts for the struggle between them and the landlords over the ascertainment of the actual results of an investment of capital (Morton). For the rent is fixed when the lease for the land is made out, and after that the surplus profits arising from excessive investments of capital flow into the pockets of the tenant so long as the lease lasts. Therefore the tenants fought for long leases, and on the other hand the landlords enforced by their superior numbers an increase of the tenancies at will, which could be cancelled annually.

It is evident from the outset that even though it is immaterial for the law forming the surplus profit, whether equal capitals are invested with unequal results side by side upon equal areas of land, or whether they are invested successively on the same land, it does make a considerable difference for the conversion of surplus profit into ground-rent. The latter method confines this conversion within boundaries, which are narrower on one side and less definite on the other. For this reason the business of the tax assessor, as Morton shows in his "Resources of Estates," becomes a very important, complicated and difficult profession in countries with an intensive cultivation (and economically we mean by intensive cultivation nothing else but the concentration of capital upon the same piece of land, instead of its distribution over adjoining pieces of land). If the improvements of the soil are of the more permanent kind, the artificially raised differential fertility of the soil coincides with its natural fertility as

soon as the lease expires, and this leads to the assessment of the rent by the basis of that which is due to the mere differences of fertility in different soils generally. On the other hand, so far as the formation of surplus profit is determined by the magnitude of the working capital, the amount of the rent paid by a certain amount of capital is added to the average rent of the country and care is taken that the new tenant commands sufficient capital to continue cultivation in the same intensive manner.

In the study of differential rent II, the following points must be noted:

Its basis and point of departure, not merely historically, but even as concerns its movements at any given period, is differential rent I, that is the simultaneous cultivation side by side of soils of different fertility and location; in other words the simultaneous application, side by side, of different portions of the total agricultural capital upon soil areas of different quality.

Historically this is a matter of course. In colonies the colonists have but little capital to invest. The principal agents of production are labor and land. Every individual head of a family seeks to acquire for himself and his, an independent field of employment, apart from that of his fellow colonists. This must be generally the case even under precapitalist modes of production in agriculture proper. In the case of sheep pastures, and generally of cattle raising as an independent line of production, the exploitation of the soil is more or less collective, and it is extensive from the outset. The capitalist mode of production starts out from former modes of production, in which the means of production are actually or legally the property of the tiller himself, in which agriculture is carried on by professionals. Naturally this mode of agriculture gives way but gradually to the concentration of means of production and their transformation into capital with a simultaneous change of direct producers into wage workers. So far as the capitalist mode of production asserts itself here in a typical manner, it does so at first mainly in sheep pastures and cattle raising; after that it does not assert itself by a concentration of capital upon a relatively small area of land, but in production on a larger scale, so that the expense of keeping horses and other costs of production may be saved; but in fact not by investing more capital in the same land. It is furthermore in the nature of

field tillage that capital, which implies at this stage also the means of production already produced, should become the dominating element of agriculture, when cultivation has reached a certain height and the soil has become correspondingly exhausted. So long as the tilled land constitutes a small area compared to the untilled, and so long as the strength of the soil has not been exhausted (and this is the case so long as cattle raising prevails with meat as the staple food, before agriculture proper and plant food have become dominant), the beginnings of the new mode of production show their opposition to peasants' economy mainly by large tracts of land which are tilled for the account of some capitalist, in other words, the new mode of production itself starts out with an extensive application of capital to larger areas of land. It should therefore be remembered from the outset, that differential rent No. I is the historical basis from which a start is made. On the other hand, the movement of differential rent No. II puts in its appearance at any given moment only upon a territory, which is itself but the variegated basis of differential rent No. I.

In differential rent No. II, the differences in the distribution of capital (and of the ability to get credit) among tenants are added to the differences in fertility. In manufacture proper, each line of business rapidly develops its own minimum volume of business and a corresponding minimum of capital, below which no individual business can be carried on successfully. In the same way each line of business develops, above this minimum, a normal size of capital, which the mass of producers must be able to command and do command. Whatever exceeds this, can form extra profits; whatever is below this, does not get the average profit. The capitalist mode of production invades agriculture but slowly and unevenly, as may be seen in England, the classic land of the capitalist mode of production in agriculture. To the extent that no free importation of cereals exists, or that its effect is but limited, because its volume is small, the producers working upon inferior soil and thus with worse than average conditions of production determine the market price. A large portion of the total mass of capital invested in husbandry and available for it is in their hands.

It is true that the farmer spends much labor on his small plot of land. But it is labor isolated from the objective social and material conditions of productivity, labor robbed and stripped of these conditions.

This circumstance makes it possible for the real capitalist tenants to appropriate a portion of the surplus profit; this would not be so, at least so far as this point is concerned, if the capitalist mode of production were as uniformly developed in agriculture as in manufacture.

Let us first consider the formation of surplus profit in differential rent No. II, without taking notice for the present of the conditions under which the conversion of this surplus profit into ground rent may take place.

It is evident, in that case, that differential rent No. II is but a different expression of differential rent No. I, but that it coincides with it in substance. The different fertility of the various kinds of soil exerts its influence in the case of differential rent No. I only to the extent that it brings about unequal results of the capitals invested in the soil, so that the products of equal capitals, or of equal aliquot parts of unequal capitals, are unequal. Whether this inequality takes place for different capitals invested successively in the same land, or for capitals invested in various tracts of different classes of soil, cannot alter anything in the differences of fertility, or in the differences of their products, nor in the formation of the differential rent for the more productively invested parts of capital. It is still the soil which shows different fertilities with the same investment of capitals, only that in this case the same soil does for a capital successively invested in different portions what different kinds of soil do in the case of differential rent No. I for various equally large portions of social capital invested in them.

If the same capital of 10 pounds sterling, which is shown by Table I to be invested in the shape of separate capitals of $2\frac{1}{2}$ pounds sterling by different tenants in one acre of each of the soils A, B, C and D, were invested successively in one and the same acre D, so that its first investment yielded 4 quarters, the second 3 quarters, the third 2 quarters and the fourth 1 quarter (or vice versa), then the price of the 1 quarter, which is furnished by the least productive capital, namely the price of 3 pounds sterling, would not pay any differential rent, but would determine the price of production, so long as the supply of wheat with a price of production of 3 pounds sterling would be needed. And since our assumption is that the capitalist

mode of production prevails, so that the price of 3 pounds sterling includes the average profit made by a capital of $2\frac{1}{2}$ pounds sterling generally, the other three portions of capital of $2\frac{1}{2}$ pounds sterling each will make surplus profits according to the difference of their product, since this product is not sold at their own price of production, but at the price of production of the least productive investment of $2\frac{1}{2}$ pounds sterling, which does not pay any rent and whose price of production is determined by the general law of prices of production. The formation of the surplus profits would be the same as in Table I.

We see here once more that differential rent No. II is conditioned upon differential rent No. I. The minimum product raised by a capital of $2\frac{1}{2}$ pounds sterling upon the worst soil is here assumed to be 1 quarter. Take it then that the tenant using soil of class D invests in this same soil, aside from the $2\frac{1}{2}$ pounds sterling which raise 4 quarters and pay a differential rent of 3 quarters, still another capital of $2\frac{1}{2}$ pounds sterling, which raise only 1 quarter, like the same capital upon the worst soil A. This would be a rentless investment, which would pay him only the average profit. There would be no surplus profit, which could be converted into rent. On the other hand, this decreasing yield of the second investment of capital in D would not have any influence on the rate of profit. It would be the same as though $2\frac{1}{2}$ pounds sterling had been invested in another acre of the soil of class A, a circumstance which would in no way affect the surplus profit, nor for that reason the differential rent of the classes A, B, C, and D. But for the tenant this additional investment of $2\frac{1}{2}$ pounds sterling in D would have been quite as profitable as the investment of the original $2\frac{1}{2}$ pounds sterling had been per acre of D, according to our assumption, although this had raised 4 quarters. Furthermore, if two other investments of $2\frac{1}{2}$ pounds sterling each should yield an additional product of 3 quarters and 2 quarters respectively, another decrease would have taken place compared with the product of the first investment of $2\frac{1}{2}$ pounds sterling in D, which amounted to 4 quarters and paid a surplus profit of 3 quarters, But it would be merely a decrease in the amount of surplus profit, and would not affect either the average profit or the regulating price of production. It would have such an effect only if the additional production yielding this decreasing surplus profit should make the production upon A superfluous and throw class A out of cultivation. In that case the decreasing fertility of the additional investments

of capital in class D would be accompanied by a fall of the price of production, for instance from 3 pounds sterling to $1\frac{1}{2}$ pounds sterling, and the class B would become the rentless regulator of the market price.

The product of D would not be $4 + 1 + 3 + 2 = 10$ quarters, whereas it was only 4 quarters formerly. But the price per quarter as regulated by B would have fallen to $1\frac{1}{2}$ pounds sterling. The difference between D and B would be $10 - 2 = 8$ quarters, at $1\frac{1}{2}$ pounds sterling per quarter, or 12 pounds sterling, whereas the money rent in D used to be 9 pounds sterling. This should be noted. Calculated per acre, the amount of the rent would have risen by $33\frac{1}{3}\%$ in spite of the decreasing rate of the surplus profits on the two additional capitals of $2\frac{1}{2}$ pounds sterling each.

We see by this to what highly complicated combinations differential rent in general, and particularly form II coupled with form I, may give rise, whereas Ricardo, for instance, treats it very onesidedly and as a simple matter. One may meet, as in the above case, with a fall of the regulating market price and at the same time with a rise of the rent upon superior soils, so that both the absolute product and the absolute surplus product grow. (In differential rent No. I, in a descending line, the relative surplus product and thus the rent per acre may increase, although the absolute surplus product per acre may remain constant or even decrease.) But at the same time the fertility of the investments of capital made successively in the same soil decreases, although a large portion of them falls upon the superior lands. From a certain point of view — both as concerns the product and the prices of production — the productivity of labor has risen. But from another point of view it has decreased, because the rate of surplus profit and the surplus product per acre decrease for the various investments of capital in the same soil.

Differential rent No. II, with a decreasing fertility of the successive investments of capital, would be necessarily accompanied with a rise of the price of production and an absolute decrease of the productivity only in the case that these investments of capital could be made on none but the worst soil A. If one acre of A, which raised with an investment of a capital of $2\frac{1}{2}$ pounds sterling 1 quarter at a price of production of 3 pounds sterling, should raise only a total of $1\frac{1}{2}$ quarters with an additional investment of $2\frac{1}{2}$

pounds sterling, or a total investment of 5 pounds sterling, then the price of production of this 1½ quarter would be 6 pounds sterling, or that of one quarter 4 pounds sterling. Every decrease of the productivity with a growing investment of capital would imply a relative decrease of the product per acre in such a case, whereas it would signify only a decrease of the surplus product upon superior soils.

The nature of the matter will carry with it the fact that with the development of intensive culture, i.e., with successive investments of capital upon the same soil, mainly the superior soils will show this tendency, or will show it to a greater degree. (We are not speaking now of permanent improvements, by which a hitherto useless soil is converted into useful soil.) The decreasing fertility of the successive investments of capital must, therefore, have principally the effect indicated above. The better soil is chosen, because it offers the best prospects that the capital invested in it will be profitable, since this soil contains the greater quantity of the useful elements of fertility, which need but be utilised.

When after the abolition of the corn laws the cultivation in England was made still more intensive, a great deal of the former wheat land was used for other purposes, particularly for cattle pastures, while the tracts best adapted to wheat and fertile were drained and otherwise improved. The capital for wheat culture was thus concentrated into a more limited area.

In this case — and all possible surplus rates between the highest surplus product of the best soil and the product of the rentless soil A coincide here, not with a relative, but with an absolute increase of the surplus product per acre — the newly formed surplus profit (eventually rent) does not represent a portion of a former average profit converted into rent (not a portion of the product in which the average profit formerly incorporated itself) but an additional surplus profit, which converted itself out of this form into rent.

Only in the case in which the demand for cereals would increase to such an extent, that the market price would rise above the price of production of A, so that for this reason the surplus product of A, B, or any other class of soil could be supplied only at a higher price than 3 pounds sterling, would the decrease of the results of an additional investment of capital in A, B, C

and D be accompanied by a rise of the price of production and of the regulating market price. To the extent that this would last for a certain length of time without calling forth the cultivation of additional soil (which should be at least of the quality of A), or without bringing on a cheaper supply through other circumstances, wages would rise in consequence of the dearness of bread, other circumstances remaining the same, and the rate of profit would fall accordingly. In this case it would be immaterial, whether the increased demand would be satisfied by drawing upon inferior soil than A, or by additional investments of capital, no matter upon which of the four classes of soil. Differential rent would then rise in connection with a falling rate of profit.

This one case, in which the decreasing fertility of additional capitals invested in already cultivated soils may lead to an increase of the price of production, a fall in the rate of profit, and a formation of higher differential rents — for this rent would rise under the given circumstances upon all classes of soil just as though inferior soil than A were regulating the market — has been stamped by Ricardo as the only case, the normal case, to which he reduces the entire formation of differential rent No. II.

This would also be the case, if only the class A of soils were cultivated, and if successive investments of capital upon it were not accompanied by a proportional increase of the product.

Here then differential rent No. I is entirely lost sight of when analysing differential rent No. II.

With the exception of this case, in which the supply from the cultivated classes of soil is insufficient, so that the market price stands continually higher than the price of production, until new soil of an inferior character is taken under cultivation in addition to the others, or until the total product of the additional capitals invested in the various classes of soil can be supplied only at a higher price of production than the hitherto customary one, with the exception of this case the proportional decrease in the productivity of the additional capitals leaves the regulating price of production and the rate of profit unchanged. For the rest three cases are possible.

If the additional capital upon any one of the classes of soil A, B, C or D yields only the rate of profit determined by the price of production of A, then no surplus profit, and therefore no rent, is formed, any more than there would be, if additional soil of the A class had been cultivated.

If the additional capital yields a larger product, then a new surplus profit (potential rent) is, of course, formed, provided the regulating price remains the same. This is not necessarily the case, namely it is not the case when this additional production throws the soil A out of cultivation and thus out of the succession of the competing soils. In this case the regulating price of production falls. The rate of profit would rise, if a fall in wages were connected with this, or if the cheaper product were to enter into the constant capital as one of its elements. If the increased productivity of the additional capital had taken place upon the best soils C and D, it would depend entirely upon the degree of the increased productivity and the mass of the additional capitals to what extent a formation of increased surplus profit (and thus increased rent) would be connected with the fall in prices and the rise of the rate of profit. This rate may also rise without a fall in wages, by a cheapening of the elements of constant capital.

If the additional investment of capital takes place with decreasing surplus profits, but in such a way that the product of such additional investment still leaves a surplus above the product of the same capital in A, a new formation of surplus profits takes place under all circumstances, unless the increased supply throws the soil A out of cultivation. This new formation of surplus profit may take place simultaneously upon all four soils, D, C, B and A. But if the worst soil A is crowded out of cultivation, then the regulating price of production falls, and it will depend upon the proportion between the reduced price of 1 quarter and the increased number of quarters yielding a surplus profit, whether the surplus profit expressed in money, and consequently the differential rent, shall rise or fall. But at any rate we meet here with the peculiarity, that in spite of decreasing surplus profits of successive investments of capital the price of production may fall, instead of rising, as it seems it ought to do at first sight.

These additional investments of capital with decreasing surplus products correspond entirely to the case, in which four new and separate capitals

would be invested in soils having a fertility ranging between A and B, B and C, C and D, for instance four capitals of $2\frac{1}{2}$ pounds sterling each and yielding $1\frac{1}{2}$, $2\frac{1}{3}$, $2\frac{2}{3}$, and 3 quarters respectively. Surplus profits (potential rents) would form upon all these kinds of soil for all four additional capitals, although the rate of surplus profit, compared with the surplus profit of the same investment of capital, on the corresponding better soil, would have decreased. And it would be immaterial, whether these four capitals were invested in D, etc., or distributed between D and A.

We now come to one essential difference between the two forms of differential rent.

With a constant price of production and constant differences, the rental and the average rent per acre, or the average rent per capital, may rise under differential rent No. I. But the average is a mere abstraction. The actual amount of the rent, calculated per acre or per capital, remains the same here.

On the other hand, under the same conditions, the amount of the rent calculated per acre may rise, although the rate of rent, measured by the invested capital, remains the same.

Let us assume that production is doubled by the investment of 5 pounds sterling in each of the soils A, B, C and D instead of $2\frac{1}{2}$ pounds sterling, a total of 20 pounds sterling instead of 10 pounds sterling, with the relative fertilities unchanged. This would be the same as though 2 acres instead of 1 were being cultivated, with the same cost, on each one of these classes of soil. The rate of profit would remain the same, also its ratio to the surplus profit or the rent. But if A were raising 2 quarters now, and B, 4, C, 6, D, 8, the price of production would nevertheless remain at 3 pounds sterling per quarter because this increment is not due to a doubled fertility of the same capital, but to the same proportional fertility of a doubled capital. The two quarters of A would now cost 6 pounds sterling, just as one quarter used to cost 3 pounds sterling. The profit would have doubled on all four classes of soils, but only because the invested capital did. But in the same proportion the rent would also have become doubled. It would now be two quarters for B instead of one, four for C instead of two, and six for D instead of three.

And corresponding to this the money rent for B, C, and D would now be 6 pounds sterling, 12 pounds sterling, and 18 pounds sterling respectively. Like the product per acre, so the rent in money per acre would be doubled, and consequently the price of the land also, in which this rent is capitalised. If calculated in this manner, the amount of the rent in grain and money rises, and thus the price of land, because the standard by which the calculation is made, the acre, is a tract of a constant magnitude. On the other hand, calculating it as the rate of rent on the invested capital, no change has taken place in the proportional amount of the rent. The total rental of 36 is proportioned to the invested capital of 20 as the rental of 18 was proportioned to the invested capital of 10. The same holds good for the ratio of the money rent of all classes of soil to the capital invested in them, for instance, 12 pounds sterling of rent in C are proportioned to 5 pounds sterling of capital, as 6 pounds sterling of rent used to be proportioned to $2\frac{1}{2}$ pounds sterling of capital. No new differences arise here between the invested capitals, but new surplus profits arise, because the additional capital is invested in one of the rent paying soils, or in all of them, with the same proportional product. If this double investment were made only in one of these soils, for instance in C, the differential rent, calculated per capital, would remain the same between C, B, and D. For while its mass is doubled in C, so is the invested capital.

This shows that the amount of rent in products and money, and with it the price of the land, may rise while the price of production, the rate of profit, and the differences of fertility remain unchanged (and with them remain unchanged the rate of surplus profit or the rent, calculated on the capital).

The same may take place with decreasing rates of surplus profits and of rent, that is, with a decreasing productivity of the rent paying additional investments of capital. If the second investments of capital of $2\frac{1}{2}$ pounds sterling had not doubled the product, but B would raise only $3\frac{1}{2}$ quarters, C, 5 quarters, and D, 6 quarters, then the differential rent for the second capital of $2\frac{1}{2}$ pounds sterling in B would be only $\frac{1}{2}$ quarter instead of one quarter, in C, one quarter instead of two, and in D, two quarters instead of three. The proportions between rent and capital for the two successive investments would then be as follows:

lf0445-03-0800-t0001.gif

In spite of this decreased rate of the relative productivity of capital and thus of surplus profit, calculated per capital, the rent in grain and money would have risen in B from one to one and a half quarter (from 3 to $4\frac{1}{2}$ pounds sterling), in C, from two quarters to three (from 6 pounds sterling to 9 pounds sterling), and in D, from three quarters to five (from 9 pounds sterling to 15 pounds sterling). In this case the differences for the additional capitals, compared with the capital invested in A, would have decreased, the price of production would have remained the same, but the rent per acre, and consequently the price of the land per acre, would have risen.

The combinations of differential rent No. II, which are conditioned upon differential rent No. I as their basis, are analysed in the following chapters.

CHAPTER XLI. DIFFERENTIAL RENT II. — FIRST CASE: CONSTANT PRICE OF PRODUCTION.

THIS assumption implies that the market price is regulated the same as ever by the capital invested in the worst soil A.

If the additional capital invested in any one of the rent paying soils B, C, D, produces no more than the same capital upon the soil A, in other words, if it pays only the average profit by means of the regulating price of production, but no surplus profit, then the effect upon the rent is nil. Everything remains as it is. It is the same as though any number of acres of the A quality, of the worst soil, had been added to the cultivated area.

The additional capital brings forth upon every one of the different soils additional products proportional to their magnitude; in other words, the volume of production grows according to the specific fertility of every class of soil, in proportion to the magnitude of the additional capital. We started out in chapter XXXIX from the following Table I:

lf0445-03-0801-t0001.gif

This table is now transformed into Table II.

lf0445-03-0802-t0001.gif

It is not necessary in this case that the investment of capital should be doubled in all classes of soil, as it does in this Table. The law is the same, so long as additional capital is invested in one, or several, of the rent paying soils, no matter in what proportion. It is only necessary that production should increase upon every kind of soil in the same ratio as the capital. The rent rises here merely in consequence of an increased investment of capital in the soil, and in proportion to this increase. This increase of the product and of the rent in consequence of, and proportionately to, the increased investment of capital is just the same, so far as the quantity of the product and of the rent is concerned, as though the cultivated area of the rent paying

lands of the same quality had been increased and taken under cultivation with the same investment of capital as that previously invested in the same classes of land. In the case of Table II, for instance, the result would remain the same, if the additional capital of $2\frac{1}{2}$ pounds sterling per acre were invested in one additional acre each of B, C and D.

This assumption, furthermore, does not imply a more productive investment of capital, but only an investment of more capital upon the area with the same success as before.

All proportional relations remain the same here. True, if we do not consider the proportional differences, but the purely arithmetical ones, then the differential rent may change upon the various classes of soil. Let us assume, for instance, that the additional capital has been invested only in B and D. In that case the difference between D and A is 7 quarters, whereas it was only 3 before; the difference between B and A is 3 quarters, whereas it was one; that between C and B is minus one, whereas it was plus one, etc. But this arithmetical difference, which is decisive in differential rent I, so far as it expresses the difference of productivity with equal investments of capital, is here quite immaterial, because it is a consequence of different additional investments, or of no additional investments, of capital, while the difference for each aliquot part of capital upon the various lands remains unchanged.

The additional capitals bring forth surplus products and thus form surplus profits, but at a decreasing rate, not in proportion to their increase.

TABLE III

lf0445-03-0803-t0001.gif

In the case of this third assumption it is again immaterial, whether the additional second investments of capital are uniformly distributed over the various classes of soil or not; whether the decreasing production of surplus profit proceeds in equal or unequal proportions; whether the additional investments of capital fall all of them upon the same rent paying class of soil, or whether they are distributed equally or unequally over soils of different quality paying rent. All these circumstances are immaterial for the law which we are developing here. The only premise is that additional

investments of capital must yield a surplus profit upon any one of the rent paying soils, but in a decreasing ratio to the amount of the increase of capital. The limits of this decrease move in the above illustration of Table III between 4 quarters = 12 p.st., the product of the first investment of capital upon the best soil D, and 1 quarter = 3 p.st., the product of the same investment of capital upon the worst soil A. The product of the best soil on the first investment of capital forms the maximum boundary, and the product of the same investment of capital in the worst soil A, which pays no rent and yields no surplus profit, forms the minimum limit of the product, which the successive investments of capital yield upon any of the various classes of soils producing a surplus profit with successive investments of capital and a decreasing productivity. Just as assumption No. II corresponds to a condition, in which new pieces of the same quality are added to the cultivated area among the superior soils, so that the quantity of any one of the cultivated soils is increased, so assumption No. III corresponds to a condition, in which additional pieces of soil are cultivated in such a way that their various degrees of fertility are distributed among soils between D and A, among soils from the best to the worst kind. If the successive investments of capital take place exclusively upon the soil D, they may include the existing differences between D and A, likewise those between D and C and those between D and B. If all the successive investments are made upon soil C, they will comprise only differences between C and A and C and B; if made exclusively upon B, only differences between B and A.

But this is the law: That the rent increases absolutely upon all these classes of soil, although not in proportion to the additional capital invested.

The rate of surplus profit, considering both the additional capital and the total capital invested in the soil, decreases; but the absolute magnitude of the surplus profit increases. In like manner the decreasing rate of profit on capital in general is generally accompanied by an absolutely increasing mass of profit. Thus the average surplus profit of the investment of capital upon B amounts to 90% on the capital, whereas it amounted to 120% on the first investment of capital. But the total surplus profit increases from one quarter to one and a half quarter, or from 3 pounds sterling to 4½ pounds sterling. Considering the total rent by itself — and not comparing it with the

doubled magnitude of the advanced capital — it has risen absolutely. The differences of the rents of the various kinds of soil and their relative proportions may vary here; but this variation in the differences is here a consequence, not a cause, of the increase of the rents compared to one another.

The case, in which the additional investments of capital upon the superior soils bring forth a greater product than the original ones, requires no further analysis. It is a matter of course that under this assumption the rent per acre will rise, and will do so at a greater rate than the additional capital, no matter upon which kind of soil the investment may have been made. In this case the additional investment of capital is accompanied by improvements. This includes the case, in which an additional investment of less capital produces the same or a greater result than did formerly an investment of more capital. This case is not quite identical with the former one, and this is a distinction, which is important in all investments of capital. For instance, if 100 make a profit of 10, and 200, employed in a certain form, make a profit of 40, then the profit has risen from 10% to 20%, and to that extent it is the same as though 50, employed in a more effective form, make a profit of 10 instead of 5. We assume here that the profit is combined with a proportional increase of the product. But the difference is this, that I must double the capital in the one case, whereas in the other I produce the double effect by the same capital. It is by no means the same whether I bring forth the same product as before with half as much living and materialized labor, or twice the product as before with the same labor, or four times the former product with twice the labor. In the first case, labor in a living or materialised form is released, which may be employed otherwise; the power to dispose of capital and labor increases. The release of capital (and labor) is in itself an augmentation of wealth; it has just the same effect as though this additional capital had been obtained by accumulation, but it saves the labor of accumulation.

Take it that a capital of 100 has produced a product of ten yards. The 100 may include both constant capital, living labor and profit. In that case one yard costs 10. Now if I can produce 20 yards with the same capital of 100, then one yard costs 5. On the other hand, if I can produce 10 yards with a capital of 50, then one yard likewise costs 5, and a capital of 50 is released,

assuming the former supply of commodities to be sufficient. Again, if I have to invest 200 of capital in order to produce 40 yards, then one yard also costs 5. The determination of the value, or price, does not indicate such differences as these, neither does the mass of products proportional to the investment of capital. But in the first case, capital is released; in the second case additional capital is saved to the extent that a duplication of production would be required; in the third case the increased product can be obtained only by an augmentation of the invested capital, although not in the same proportion as it would be if the increased product had to be supplied by the old productive power. (This belongs in Part I.)

From the point of view of capitalist production the employment of constant capital is always cheaper than that of variable capital, not where it is a question of increasing the surplus-value, but of reducing the cost price. For a saving of costs even in the element creating the surplus-value, labor, performs this service for the capitalist and makes profit for him, so long as the regulating price of production remains the same. This presupposes in fact the existence of a development of credit and of an abundance of loan capital corresponding to the capitalist mode of production. On the one hand I employ 100 pounds sterling of additional constant capital, if 100 pounds sterling are the product of five laborers during one year; on the other hand, 100 pounds sterling in variable capital. If the rate of surplus-value is 100%, then the value created by those five laborers in 200 pounds sterling; on the other hand, the value of 100 pounds sterling of constant capital is 100 pounds sterling, or perhaps 105 pounds sterling in its capacity as loan capital, if the rate of interest is 5%. The same sums of money express largely different values in product, according to whether they are advanced to production as values of constant or variable capital. Furthermore, as concerns the cost of the commodities from the point of view of the capitalist, there is also this difference that of 100 pounds sterling of constant capital only the wear and tear passes into the value of the product to the extent that this money is invested in fixed capital, whereas 100 pounds sterling invested in wages pass wholly into the values of commodities and must be reproduced in them.

In the case of colonists and of independent small producers in general, who have no command at all over capital or at least command it only at a

high rate of interest, that part of the product which stands in place of wages is their revenue, whereas it constitutes an investment of capital for the capitalist. The colonist, therefore, regards this expenditure of labor as the indispensable prerequisite of his product, which is the thing that interests him first of all. As for his surplus-labor, after deducting that necessary labor, it is evidently realised in a surplus-product and as soon as he can sell this, or even use it for himself, he looks upon it as something that cost him nothing, because it cost him no materialised labor. It is only the expenditure of materialised labor which appears to him as an outlay of wealth. Of course, he tries to sell as high as possible; but even a sale below value and below the capitalist price of production still appears to him as a profit, unless this profit is claimed beforehand by debts, mortgages, etc. But for the capitalist the investment of both variable and constant capital represents an outlay of capital. The relatively large outlay of the capitalist reduces the cost-price, and in fact the value of commodities, provided other circumstances remain the same. Hence, although the profit arises only from surplus-labor, consequently only from the employment of variable capital, still it may seem to the individual capitalist that living labor is the most expensive element of his cost of production, which should be reduced to a minimum above all others. This is but a capitalistically distorted form of the correct view that the relatively greater use of past labor, compared to living labor, signifies an increase in the productivity of social labor and a greater social wealth. From the point of view of competition, everything appears thus distorted and invested.

Assuming the prices of production to remain unchanged, additional investments of capital may be made with an unaltered, an increasing, or a decreasing productivity upon the better soils, that is upon all soils from B upward. Upon soil A this would be possible, under the conditions assumed by us, only in the case that productivity should remain the same, in which case this land continues to pay no rent, or in the case that productivity increases in which case a portion of the capital invested in A would produce rent, while the remainder would not. But it would be impossible, if the productivity upon A were to decrease, for in that case the price of production would not remain unchanged, but would rise. But under all these circumstances the surplus-product and the surplus-profit corresponding to it increases per acre, and with them eventually the rent, in grain or in money,

regardless of whether the surplus-product yielded by them is proportional to their magnitude, or above or below this proportion, regardless of whether the rate of the surplus-profit of capital remains constant, rises or falls when this capital increases. The growth of the mere mass of surplus-profit, or of the rent calculated per acre, that is, an increasing mass calculated on the same unaltered unit, in the present case on a definite quantity of land, such as an acre or an hectare, expresses itself as an increasing ratio. Hence the magnitude of the rent, calculated per acre, increases under such circumstances simply in consequence of the increase of the capital invested in the soil. This takes place when the price of production remain the same, no matter whether the productivity of the additional capital stays unaltered, or decreases, or increases. These last named circumstances modify the volume, in which the level of the rent per acre rises, but not the fact of this increase itself. This is a phenomenon, which is peculiar to differential rent No. II and distinguishes it from differential rent No. I. If the additional investments of capital, instead of being made successively one after another upon the same soil, were made side by side upon new additional soil of the corresponding quality, the mass of the rental would have increased, and, as previously shown, the average rent of the cultivated total area would likewise have increased, but not the size of the rent per acre. When results remain the same so far as the mass the value of the total production and of the surplus product are concerned, the concentration of capital upon a smaller area of land develops the size of the rent per acre, whereas its distribution over a larger area, under the same circumstances, and other circumstances remaining the same, does not produce this effect. But the more the capitalist mode of production develops, the more develops also the concentration of capital upon the same area of land, and the higher rises the rent calculated per acre. Consequently, if we have two countries, in which the prices of production are identical, the differences of the various kinds of soil the same, and the same amount of capital invested, but in such a way that the investment is made in the form of successive outlays upon a limited area in one country, whereas in the other country it is made more in the shape of co-ordinated outlays upon a wider area, then the rent per acre, and with it the price of land, would be higher in the first and lower in the second country, although the mass of the rent would be the same in both countries. The difference in the size of the rent could not be explained in such a case out of the natural fertility of the various kinds of soil, nor out of the quantity

of employed labor, but solely out of the different ways in which the capital is invested.

In speaking of a surplus-product in this case, we mean that aliquot part of the product, in which the surplus-profit presents itself. Ordinarily we mean by surplus-product that portion of the product, in which the total surplus-value is materialised, or in some cases that portion, in which the average profit presents itself. The specific significance, which this term assumes in the case of rent-paying capital, give rise to misunderstanding, as we have shown in another place.

CHAPTER XLII. DIFFERENTIAL RENT II. — SECOND CASE: FALLING PRICE OF PRODUCTION.

THE price of production may fall, when the additional investments of capital take place with an unaltered, a falling, or a rising rate of productivity.

The Productivity of the Additional Investment of Capital Remains the Same.

In this case the assumption is that the product increases in the same proportion as the capital invested in the various soils and in accordance with their respective qualities. This implies, always assuming the differences of the various soil to remain unaltered, that the surplus-product increases in proportion to the increased investment of capital. This case, then, excludes any additional investment of capital upon soil A which might affect the differential rent. Upon this soil the rate of surplus-profit is 0; it remains 0, since we have assumed that the productive power of the additional capital and therefore the rate of surplus-profit remain the same.

But under these conditions the regulating price of production can fall only, because instead of the price of production of A that of the next best soil B, or of any better soil than A, becomes the regulator; so that the capital is withdrawn from A, or perhaps from B and A, in case the price of production of C should become the regulating one and all inferior soil should be eliminated from the competition of the wheat raising soils. The prerequisite for this would be, under the assumed conditions, that the additional product of the additional investments of capital should satisfy the demand, so that the product of the inferior soils A, etc., would become superfluous for the formation of a full supply.

Take, for instance, Table II, but in such a way that 18 quarters instead of 20 will satisfy the demand. Soil A would drop out; D and its price of

production of 30 shillings would become regulating. In that case the differential rent would assume the following form:

lf0445-03-0811-t0001.gif

In other words, compared to Table II the ground-rent would have fallen in money from 36 pounds sterling to 9 pounds sterling and in grain from 12 quarters to 6 quarters, whereas the total output would have fallen only by 2, from 20 to 18. The rate of surplus-profit, calculated on the capital, would have fallen by one-half, from 180% to 90%. The fall of the price of production in this case is accompanied by a decrease of the rent in grain and money.

Compared to Table I there is merely a decrease in the money rent; the rent in grain in both cases is 6 quarters. But in the one case these bring 18 pounds sterling, in the other only 9 pounds sterling. So far as the soils C and D are concerned, the rent in grain compared to Table I remains the same. In face, owing to the additional production put forth by the uniformly working additional capital, the product of A has been pushed out of the market, the soil A has been eliminated from the competition of the producing agents, and a new differential rent No. 1 has thus been formed, in which the better soil B plays the same role as formerly the inferior soil A. Consequently the rest of B disappears on the one side; on the other side nothing has been altered in the differences of B, C and D by the investment of additional capital, according to our assumption. For this reason that part of the product, which is converted into rent, is reduced.

If the above result, the satisfaction of the demand with A left out, should have been accomplished by the investment of more than double the capital upon C or D, or upon both, then the matter would assume a different aspect. Let us suppose, that a third investment of capital is made upon C.

lf0445-03-0812-t0001.gif

In this case, compared to Table IV, the product of C has risen from 6 quarters to 9, the surplus product from 2 quarters to 3, the money rent from 3 pounds sterling to 4½ pounds sterling. Compared to Table II, in which the money rent was 12 pounds sterling, and Table I, in which it was 6 pounds sterling, it has fallen off. The total rental in grain is 7 quarters. It has fallen

compared to Table II, in which it was 12 quarters, but has risen compared to Table I, in which it was 6 quarters. In money the rest is $10\frac{1}{2}$ pounds sterling and has fallen compared to both of the other Tables, in which it was 18 and 36 pounds sterling respectively.

If the third investment of capital, amounting to $2\frac{1}{2}$ pounds sterling, had been applied to soil B, it would indeed have altered the quantity of production, but would not have touched the rent, since the successive investments, according to our assumption, do not produce any differences upon the same soil, and soil B does not produce any rent.

Again, if we assume that the third investment of capital takes place upon D instead of C, we get

lf0445-03-0813-t0001.gif

Here the total product is 22 quarters, more than double that of Table I, although the invested capital is only $17\frac{1}{2}$ pounds sterling as against 10 pounds sterling, in other words, not twice the size. The total product is also larger by 2 quarters than that of Table II, although the capital in it is larger, namely 20 pounds sterling.

Compared to Table I, the rent in grain upon soil D has increased from 2 quarters to 6, whereas the money rent has remained the same, 9 pounds sterling. Compared to Table II the grain rent of D is the same, namely 6 quarters, but the money rent has fallen from 18 pounds sterling to 9 pounds sterling.

Comparing the total rents, the grain rent of IV b is 8 quarters, larger than that of I which is 6 and than that of IV a which is 7 quarters; but it is smaller than that of II which is 12 quarters. The money rent of IV b, 12 pounds sterling, is larger than that of IV a, which is $10\frac{1}{2}$ pounds sterling, and smaller than that of Table I, which is 18 pounds sterling and that of Table II, which is 36 pounds sterling.

In order that the total rental under the conditions of Table IV b, after the elimination of the rent upon B, may be equal to that of Table I, we need 6

pounds sterling of surplus product more, that is, 4 quarters at $1\frac{1}{2}$ pounds sterling, which is the new price of production. Then we shall have once more a total rental of 18 pounds sterling, the same as in Table I. The magnitude of the required additional capital will differ, according to whether we invest it upon C or D, or distribute it between these two.

In the case of C 5 pounds sterling of capital result in a surplus product of 2 pounds sterling, consequently 10 pounds sterling of additional capital will result in 4 quarters of additional surplus product. In the case of D 5 pounds sterling of additional capital would suffice for the purpose of producing 4 quarters of additional grain rent, under the conditions assumed here, namely that the productivity of the additional investments of capital will remain the same. We should then get the following Tables:

lf0445-03-0814-t0001.gif

lf0445-03-0814-t0002.gif

The total money rental would be exactly one-half of what it was in Table II, where the additional capitals were invested under conditions, in which the prices of production remained the same.

The most important thing is to compare the above Tables with Table I.

We find that the total money rental has remained the same, namely 18 pounds sterling, while the price of production has fallen by one-half, from 60 shillings to 30 shillings per quarter, and that the grain rent has been correspondingly duplicated, from 6 quarters to 12. The rent upon B has disappeared; the money rent has risen by one-half in IV c, but fallen by one-half in IV d; upon D the money rent has remained the same, 9 pounds sterling, in IV c, and has risen from 9 pounds sterling to 15 pounds sterling in IV d. The production has risen from 10 quarters to 34 in IV c, and to 30 quarters in IV d; the profit from 2 pounds sterling to $5\frac{1}{2}$ pounds sterling in IV c and to $4\frac{1}{2}$ pounds sterling in IV d. The total investment of capital has risen in one case from 10 pounds sterling to $27\frac{1}{2}$ pounds sterling, and in the other from 10 pounds sterling to $22\frac{1}{2}$ pounds sterling, in either case by more than one-half. The rate of rent, that is, the rent calculated on the invested capital, is everywhere the same in all the Tables from IV to IV d for the respective kinds of soils, for this was implied by the assumption that

every kind of soil should retain the same rate of productivity with the two successive investments of capital. But compared to Table I, this rate has fallen, both for the average of all kinds of soil and for each one of them individually. In Table I it was 180% on an average, whereas in IV c it is $(18 \div 27\frac{1}{2}) \times 100 = 65 \frac{5}{11}\%$ and in IV d it is $(18 \div 22\frac{1}{2}) \times 100 = 80\%$. The average money rent per acre has risen. Formerly, in Table I, its average was $4\frac{1}{2}$ pounds sterling per acre upon all four acres, whereas now, in IV c and IV d, it is 6 pounds sterling per acre upon the three acres. Its average upon the rent paying soil was formerly 6 pounds sterling, whereas now it is 9 pounds sterling per acre. Hence the money value of the rent per acre has risen, and represents now double the grain product that it did formerly; but the 12 quarters of grain rent are now less than one-half of the total product of 33 and 27 quarters respectively, whereas in Table I the 6 quarters represent $\frac{3}{5}$ ths of the total product of 10 quarters. Consequently, although the rent as an aliquot part of the total product has fallen, and has also fallen when calculated on the invested capital yet its money-value, calculated per acre, has risen and still more its value as a product. If we take soil D in Table IV d, we find that the cost of production expended in it amounts to 15 pounds sterling, of which $12\frac{1}{2}$ pounds sterling are invested capital. The money rent is 15 pounds sterling. In Table I, for the same soil D, the cost of production was 3 pounds sterling, the invested capital $2\frac{1}{2}$ pounds sterling the money rent 9 pounds sterling, that is, the money rent amounted to three times the cost of production and almost four times the capital. In Table IV d, the money rent for D, 15 pounds sterling, is exactly equal to the cost of production and only by $\frac{1}{5}$ th larger than the capital. Nevertheless the money rent per acre is two-thirds larger, namely 15 pounds sterling instead of 9 pounds sterling. In Table I the grain rent of 3 quarters constitutes three quarters of the total product of 4 quarters; in Table IV d it is 10 quarters, or one-half of the total product of 20 quarters of one acre of D. This shows that the money value and grain value of the rent per acre may rise, although it forms a smaller aliquot part of the total yield and has fallen in proportion to the invested capital.

The value of the total product in Table I is 30 pounds sterling. The rent is 18 pounds sterling, more than one-half of it. The value of the total product of IV d is 45 pounds sterling, the rent is 18 pounds sterling, or less than one-half of it.

The reason, why in spite of the fall of the price by $1\frac{1}{2}$ pounds sterling per quarter, a fall of 50%, and in spite of the reduction of the competing soil from 4 acres to 3, the total rent remains the same and the grain rent is doubled, while on a calculation per acre both the grain rent and money rent rise, is that more surplus product is created. The price of grain falls by 50%, the surplus product increases by 100%. But in order to accomplish this result, the total production under the conditions assumed by us must be trebled, and the investment of capital upon the superior soils must be more than doubled. In what proportion this last factor must increase, depends in the first place upon the distribution of the additional investments of capital among the superior and best kinds of soil, always assuming that the productivity of the capital upon every kind of soil increases proportionately to its size.

If the fall of the price of production were smaller, less additional capital would be required for the production of the same money rent. If the supply required for the purpose of throwing soil A out of cultivation — and this depends not merely upon the product per acre of A, but also upon the proportional share taken by A in the entire cultivated area — were larger, and with it also the amount of additional capital required upon better soils than A, then, other circumstances remaining the same, the money rent and the grain rent would have increased still more, although both of them would disappear upon the soil B.

If the eliminated capital of A had been 5 pounds sterling, we should have to compare Tables II and IV d: The total product would have increased from 20 quarters to 30. The money rent would be only half as large, that is, 18 pounds sterling instead of 36 pounds sterling; the grain rent would be the same, namely 12 quarters.

If a total product of 44 quarters, valued at 66 pounds sterling, could be produced upon D with a capital of $27\frac{1}{2}$ pounds sterling — corresponding to the old rate of D, 4 quarters per $2\frac{1}{2}$ pounds sterling of capital — then the total rental would once more reach the level of Table II, and we should get the following diagram:

lf0445-03-0817-t0001.gif

The total production would be 54 quarters as against 20 quarters in Table II, and the money rent would be the same, 36 pounds sterling. But the total capital would be $37\frac{1}{2}$ pounds sterling, whereas it was 20 in Table II. The invested total capital would almost be doubled, while production would be nearly trebled; the grain rent would have been doubled, the money rent would have remained the same. Hence, if the price falls as a result of the investment of additional money-capital, while productivity remains the same, upon the better soils which pay rent, that is, all soils above A, then the total capital has a tendency not to increase in the same proportion as the production and the grain rent; so that the increase of the grain rent may offer a compensation for the loss in money rent due to the falling price. The same law also manifests itself through the fact that the invested capital must be larger in proportion as it is more largely invested upon C than D, upon the soils paying a smaller rent rather than upon the soils paying a larger rent. The point is simply this: In order that the money rent may remain the same or rise, a certain additional quantity of surplus product must be created, and this requires less capital in proportion as the productivity of the soils yielding a surplus product is greater. If the difference between B and C, C and D were still greater, still less additional capital would be required. The proportion is determined 1) by the proportion in which the price falls, in other words, by the difference between soil B, which is not paying any rent now, and soil A, which formerly was the soil that did not pay any rent; 2) by the proportion between the differences of the better soils from B upward; 3) by the amount of newly invested additional capital, and 4) by its distribution among the different qualities of soil.

In fact, we see that this law expresses merely the same thing which we ascertained already in the case of the first illustration: When the price of production is given, no matter what may be its figure, the rent may increase in consequence of additional investments of capital. For owing to the elimination of A, we have now a new differential rent No. I with B as the worst soil and $1\frac{1}{2}$ pounds sterling per quarter as the new price of production? This applies to Tables IV as well as to Table II. It is the same law, only that we have as a basis soil B instead of A, and a price of production of $1\frac{1}{2}$ pounds sterling instead of 3 pounds sterling.

The important thing here is this: To the extent that so and so much additional capital was necessary for the purpose of withdrawing the capital from soil A and satisfying the supply without it, we find that this may be accompanied by an unaltered, a rising, or a falling rent per acre, if not upon all soils, then at least upon some and so far as the average of the cultivated lands is concerned. We have seen that the grain rent and the money rent do not maintain a uniform ratio to one another. However, it is merely due to tradition that grain rent is still playing any role at all in political economy. One might demonstrate equally well that a manufacturer can buy much more of his own yarn with his profit of 5 pounds sterling than he could formerly with a profit of 10 pounds sterling. It shows at any rate, that the landlords, when they are at the same time owners or partners of manufacturing establishments, sugar factories, distilleries, etc., may still make a considerable profit even when the money rent is falling, in their capacity as producers of their own raw materials.¹²⁸

The Rate of Productivity of the Additional Capitals Decreases.

This does not carry anything new into the problem, in so far as the price of production may also fall in this case as in the previously considered one, when additional investments of capital upon better soils than A make the product of A superfluous and withdraw the capital from A, or lead to the employment of A for the production of other things. We have analysed this eventuality exhaustively. We have shown that in this case the rent in grain and money per acre may increase, decrease, or remain unchanged.

For the purpose of easy comparison we reproduce

lf0445-03-0820-t0001.gif

Now let us assume that the figure of 16 quarters, supplied by B, C, D, with a decreasing rate of productivity, suffices to throw A out of cultivation. In that case Table III is transformed into the following

lf0445-03-0820-t0002.gif

Here the rate of productivity of the additional capitals is decreasing, and the decrease is different upon different soils, while the regulating price of production has fallen from 3 pounds sterling to $1 \frac{5}{7}$ pounds sterling. The

investment of capital has risen by one-half, from 10 pounds sterling to 15 pounds sterling. The money rent has fallen by almost one-half, from 18 pounds sterling to $9\frac{3}{7}$ pounds sterling, while the grain rent has fallen only by one-twelfth, from 6 quarters to $5\frac{1}{2}$ quarters. The total product has risen from 10 to 16, or by 160%. The grain rent constitutes a little more than one-third of the total product. The advanced capital has a ratio of 15 to $9\frac{8}{7}$ to the money rent, whereas formerly this ratio was 10 to 18.

The Rate of Productivity of the Additional Capitals Increases.

This differs from Case I in the beginning of this chapter, in which the price of production falls while the rate of productivity remains the same, merely by the fact that soil A is thrown more quickly out of competition, if an increase of the product is required to effect this.

This may work its effects differently, according to the distribution of the investments over the various soils, no matter whether productivity be rising or falling. In proportion as these different effects balance the differences, or accentuate them, the differential rent of the better soils, and with it the total rental, will fall or rise, as we have seen in discussing differential rent No. I. For the rest, everything depends upon the size of the area and of the capital, which are thrown out of competition together with soil A, and upon the relative advanced of capital required with a rising productivity for the purpose of supplying the capital which is to cover the demand.

The only point which it is worth while to analyse here, and which alone carries us back to the investigation of the way in which this differential profit is converted into differential rent, is the following:

In the first case, in which the price of production remains the same, the additional capital which may be invested in the soil A is immaterial for the differential rent as such, since this soil A does not yield any rent now any more than it did before, the price of its product remains the same and continues to regulate the market.

In the second case of Variant No. I, in which the price of production falls while the rate of productivity remains the same, soil A will necessarily be

thrown out, and still more so in Variant No. II, in which both the price and production and the rate of productivity fall, since otherwise the additional capital upon soil A would have to raise the price of production. But here, in Variant No. III of the second case, in which the price of production falls, because the productivity of the additional capital rises, this additional capital may eventually be invested upon the soil A as well as upon the better soils.

We will assume that an additional capital of $2\frac{1}{2}$ pounds sterling, when invested upon the soil A, produces $1\frac{1}{5}$ quarter instead of 1 quarter.

1f0445-03-0822-t0001.gif

This Table VI should be compared with both Basic Tables I and Table II, in which the double investment of capital is combined with a constant productivity proportional to the investment of capital.

According to our assumption the regulating price of production falls. If it were to remain constant, at 3 pounds sterling, then the worst soil which used to pay no rent with an investment of $2\frac{1}{2}$ pounds sterling, would then yield a rent, although no worse soil would have been drawn into cultivation. This would have been accomplished by increasing the productivity of this soil, but only for a part, not for the original capital invested in it. The first 3 pounds sterling of cost of production bring 1 quarter; the second bring $1\frac{1}{5}$ quarter; but the entire product of $2\frac{1}{5}$ quarters is now sold at its average price.

Since the rate of productivity increases with the additional investment of capital, this implies an improvement. This may consist of a general increase of the capital per acre (more fertilizer, more mechanical labor, etc.), or it may be due exclusively to this additional investment that any difference in the quality and productiveness of the investment is brought about. In both cases the investment of 5 pounds sterling of capital per acre brings forth a product of $2\frac{1}{5}$ quarters, whereas the investment of the one-half of this capital, or $2\frac{1}{2}$ pounds sterling, brought forth a product of only 1 quarter. The product of the soil A, leaving aside the question of transient market conditions, could not continue to be sold at a higher price of production instead of all the new average price unless a considerable area of the class A

would remain under cultivation with a capital of only $2\frac{1}{2}$ pounds sterling. But as soon as the new scale of 5 pounds sterling of capital per acre would become universal, and with it an improvement of cultivation, the regulating price of production would have to fall to 2 8-11 pounds sterling. The difference between the two portions of capital would disappear, and in that case the cultivation of one acre of soil A with a capital of only $2\frac{1}{2}$ pounds sterling would be abnormal, would not correspond to the new conditions of production. It would then no longer be a difference between the yields of different portions of capital upon the same acre, but between a sufficient and an insufficient investment of capital per acre. This shows, 1), that an insufficient capital in the hands of large number of capitalist farmers (it must be a large number, for a small number would simply be compelled to sell below their price of production) produces the same effect as a differentiation of soils in a descending line. The inferior cultivation upon inferior soil increases the rent upon the superior soils; it may even create a rent upon better cultivated soil of the inferior kind, which would otherwise yield no rent. It shows, 2), that differential rent, to the extent that it arises from successive investments of capital in the same total area, resolved itself in reality into an average, in which the effects of the different investments of capital are no longer visible and distinguishable, so that the worst soil does not yield any rent, but rather, a), the average price or the total product of, say, one acre of A is made the new regulating price, and, b), the effects of the different investment of capital appear as changes in the total quantity of capital per acre, which is required under the new conditions for the adequate cultivation of the soil, and thus the individual successions of invested capital as well as their respective effects are indistinguishably amalgamated. It is the same with the individual differential rents of the superior kinds of soil. In every case they are determined by the difference of the average products of the various soils, compared to the product of the worst soil, with the increase of capital which has become the normal one.

No soil yields any product without an investment of capital. Even in the case of simple differential rent, or differential rent No. I, some capital must be invested. When we say that one acre of class A, which regulates the price of production, gives so and so much of a product at that and that price, and that the superior soils B, C and D yield so much differential product and so much money rent at the regulating price of production, it is always

understood that a certain amount of capital is invested in A which is normal under the prevailing conditions. In the same way a certain minimum capital is required for every individual line of industry, in order that commodities may be produced at their price of production.

If this minimum is altered in consequence of successive investments of capital which are accompanied by improvements, it is done gradually. So long as a certain number of acres, say, of A, do not receive this additional first capital, a rent is created upon the better cultivated portions of A by the unaltered price of production, and the rent of all superior soils, such as B, C, D, is raised. But as soon as the new method of cultivation has become general enough to be the normal one, the prices of production falls; the rent of the superior soils declines then, and that portion of the soil A, which does not enjoy the normal running capital, must sell its product below its individual price of production, and therefore below the average profit.

In the case of a falling price of production this happens also, even assuming the productivity of the additional capital to be decreasing, as soon as the required total product is supplied in consequence of increased investments of capital by the superior classes of soil, so that the running capital is withdraw, say, from A and A does not compete any longer in the production of this one staple, say wheat. The quantity of capital, which is now required on an average as an investment upon the new regulating soil, B, is now considered the normal one; and when we speak of the different fertility of the soils, it is understood that this new normal quantity of capital is employed per acre.

On the other hand, it is evident that this average investment of capital, for instance 8 pounds sterling per acre in England before 1848, and 12 pounds sterling after that year, will form the standard in the making of leases for land. For any capitalist farmer spending more than that the surplus profit does not assume the form of rent during the time of his contract. Whether this takes place after the expiration of his contract, will depend upon the competition of the capitalist farmers, who are in a position to make the same extra advance. We are not speaking here of such permanent improvements of the soil as continue to guarantee an increased product with the same or with even a decreasing investment of capital. Such

improvements, although products of capital, have the same effect as the natural differences of quality of the land.

We see, then, that an element must be considered in the case of differential rent No. II, which does not appear in differential rent No. I as such, since this last rent may continue independently of any change in the normal investment of capital per acre. It is on one hand the obliteration of the results of different investments of capital upon the regulating soil A, the product of which now appears simply as a normal average product per acre. It is on the other hand the change in the average minimum, or in the average magnitude of invested capital per acre, so that this change presents itself as a quality of the soil. It is finally the difference in the manner of transforming surplus profit into the form of rent.

Table VI shows furthermore, compared with Tables I and II, that the grain has increased more than double as compared to I, and by 1 1/5 quarters as compared to II; while the money rent has doubled as compared to I, but has not changed as compared with II. It would have increased considerably, if (other conditions remaining the same) the additional capital had been placed more upon the superior soils, or if the effects of the addition of capital to A had been less appreciable, so that the regulating average price of the quarter from A had stood higher.

If the increase of productivity by means of additional capital should produce different results upon different soils, it would cause a change in their differential rents.

At any rate we have demonstrated, that the rent per acre, for instance with a doubled capital, may not only be doubled, but more than doubled, while the price of production is falling in consequence of an increased rate of productivity of the additional capitals (as soon as the productivity grows at a greater rate than the advance of capital). But it may also fall, if the price of production should fall much lower as a result of a more rapid increase of productivity upon the soil A.

Let us assume that the additional investments of capital, for instance upon B and C, do not increase the productivity as much as they do upon A,

so that the proportional differences would decrease for B and C, and the increase of the product did not make up for the fall in price, then, compared to Table II, the rent upon D would rise, and would fall upon B and C:

lf0445-03-0826-t0001.gif

Finally, the money rent would rise, if more additional capital were invested upon the superior soils under the same proportional increase of fertility than upon A, or if the additional investments of capital upon the superior soils worked with an increasing rate of productivity. In both cases the differences would increase.

The money rent falls, when the improvement due to additional investments of capital which reduces the differences all over, or in part, affects A more than B and C. It falls so much the more, the less the productivity of the superior soils increases. It depends upon the proportion of inequality in the effects, whether the grain rent shall rise, fall, or remain stationary.

The money rent rises, and so does the grain rent, assuming the proportional difference in the additional fertility of the different soils to remain unaltered, when more capital is added to the rent paying soils than to the rentless soil A, and more capital placed upon the soils with high than those with low rents, or when the fertility, assuming the same additional capital to be used, increases more upon the better and best soils than upon A, and at that in proportion as this increase in fertility is greater upon the better classes of soil than upon the lesser ones.

But under all circumstances the rent rises relatively, when the increased productive power is a result of an addition of capital, and not merely a result of increased fertility with an unaltered investment of capital. This is the absolute point of view, which shows that here, as in former cases, the rent and the increased rent per acre (as in the case of differential rent I upon the entire cultivated area — the amount of the average rental) are a result of an increased investment of capital in the soil, no matter whether this capital does its work with a constant rate of productivity at constant or decreasing prices, or with a decreasing rate of productivity at constant or falling prices, or with an increasing rate of productivity at falling prices. For our

assumption of a constant price with a constant, falling, or rising rate of productivity of the additional capitals, and of a falling price with a constant, falling, or rising rate of productivity, resolves itself into a constant rate of productivity of the additional capital at constant or falling prices, a falling rate of productivity at constant or falling prices, and a rising rate of productivity at constant and falling prices. Although the rent may remain stationary or may fall in all these cases, it would fall more, if the additional investment of capital, other circumstances remaining the same; were not a prerequisite of an increased fertility. An addition of capital, then, is always the cause of the relative magnitude of this rent, although it may have decreased absolutely.

CHAPTER XLIII. DIFFERENTIAL RENT NO. II. — THIRD CASE: RISING PRICE OF PRODUCTION.

[A RISING price of production presupposes that the productivity of the least productive quality of land, which pays no rent, decreases. The regulating price of production cannot rise above 3 pounds sterling per quarter, unless the 2½ pounds sterling invested in soil A produce less than one-quarter, or the 5 pounds sterling less than two-quarters, or unless, even inferior soil than A has to be taken under cultivation.

If the productivity of the second investment of capital should remain the same, this would be possible only in the case that the productivity of the first investment of capital would have decreased. This case occurs often enough. It happens, for instance, when the top soil, exhausted and superficially plowed, produces inferior crops with the old style of cultivation, and when the subsoil, thrown up by deeper plowing, produces better crops than formerly under a more rational treatment. But strictly speaking this special case does not belong here. The falling off in the productivity of the first investment of 2½ pounds sterling implies for the superior soils, even when conditions with them should be analogous, a decrease of the differential rent No. I; but here we are considering only differential rent No. II. Since the present special case cannot occur without the previous existence of differential rent No. II, but represents in fact a reaction of a certain modification of differential rent No. I upon No. II, we will give an illustration of it.

lf0445-03-0829-t0001.gif

The money rent, and the yield in money, are the same as in Table II. The increased regulating price of production makes up exactly for what has been lost in the quantity of the product; since both of them vary in an inverse proportion, it is a matter of course that the product of both will remain the same.

In the above case we had assumed that the productive power of the second investment of capital was higher than the original productivity of the first investment. The matter remains the same, if we assume that the second investment has only the same productivity as that of the first, as shown in the following:

lf0445-03-0829-t0002.gif

Here likewise the rising of the price of production at the same ratio fully compensates for the decrease in the productivity both in the yield and rent in money.

The third case shows itself in its pure form only when the second investment of capital declines in its productivity, while that of the first remains constant, as assumed everywhere in the first and second cases. Here differential rent No. I is not touched, the change affects only that part which arises from differential rent No. II. We give below two illustrations: In the first we assume that the productivity of the second investment of capital has been reduced by one-half, in the second by one-fourth.

lf0445-03-0830-t0001.gif

Table IX is the same as Table VIII, only that the decrease in productivity in VIII falls upon the first investment of capital, and in IX upon the second investment of capital.

lf0445-03-0830-t0002.gif

In this table, likewise, the total yield, the money rental, and the rate of rent remain the same as in Tables II, VII and VIII, because the product and the selling price have once more varied in an inverse proportion, while the invested capital has remained the same.

But how do matters stand in the other case, which is possible with a rising price of production, namely in the case that a soil, which so far was too poor to be cultivated, is taken under cultivation?

Let us suppose that such a soil, which we will designate by a, is entering into competition. Then the hitherto rentless soil A would yield a rent, and

the foregoing Tables VII, VIII and X would assume the following forms:

lf0445-03-0831-t0001.gif

lf0445-03-0831-t0002.gif

lf0445-03-0831-t0003.gif

By the interpolation of soil a there arises a new differential rent No. I. Upon this new basis differential rent No. II likewise develops in an altered form. The soil a has a different fertility in every one of the above three Tables. The series of successively increasing productivities begins only with soil A. The series of rising rents corresponds to this. The rent of the least rent producing soil forms a constant magnitude, which is simply added to all higher rents; only after the deduction of this constant magnitude does the series of differences clearly appear among the higher rents, and so does its parallelism with the succession of fertilities of the various kinds of soil. In all Tables, the fertilities from A to D have a proportion of 1: 2: 3 : 4, and the rents are correspondingly in VIIa as $1 : 1+7 : 1+2\times 7 : 1+3\times 7$, in VIIIa as $1\frac{1}{5} : 1\frac{1}{5} + 7\frac{1}{5} : 1\frac{1}{5} + 2\times 7\frac{1}{5} : 1\frac{1}{5} + 3\times 7\frac{1}{5}$, and in Xa as $\frac{2}{3} : \frac{2}{3} + 6\frac{2}{3} : \frac{2}{3} + 2\times 6\frac{2}{3} : \frac{2}{3} + 3\times 6\frac{2}{3}$. In brief, if the rent of A = n, and the rent of the soil of next higher fertility = n + m, then the series is as n : n + m : n + 2m : n + 3m, etc. — F. E.]

[Since the foregoing third case had not been elaborated in the manuscript, only its title being there, the editor had to supplement the work as he did above. It remains now to draw the general conclusions following from the entire foregoing analysis of differential rent in its three principal cases and nine subcases. The illustrations chosen in the manuscript do not suit this purpose very well. In the first place, they compare pieces of land, equal portions of which have yields at the ratio of 1 : 2 : 3 : 4. These are differences, which strongly exaggerate and which lead to utterly forced results in the further development of the assumptions and calculations made upon this basis. In the second place, these proportions create a wrong impression. If degrees of fertility of the proportion 1 : 2 : 3 : 4, etc., produce rents in a series of 0 : 1 : 2 : 3 : 4, etc., one feels tempted to derive the second series from the first and to explain the duplication, triplication, etc., of the rents out of the duplication, triplication, etc., of the total yields. But this would be wholly incorrect. The rents show proportions like that of 0 : 1 : 2 : 3 : 4 even when the degrees of fertility are proportioned as n : n + 1 : n

+ 2 : n + 3 : n + 4; the rents are not proportioned as the degrees of fertility, they are rather proportioned as the differences of fertility, beginning with the rentless soil as a zero point.

The tables of the original had to be given for the illustration of the text. But in order to obtain a suitable basis for the following results of our analysis, I present below a new series of tables, in which the yields are indicated in bushels (1/8 quarter or 36.35 liters) and shillings.

The first of these tables, Table XI, corresponds to the former Table I. It shows the yields and rents for five qualities of soil, A to E, with a first investment of a capital of 50 shillings, which makes a profit of 10 shillings, so that the total cost of production per acre is 60 shillings. The yields in grain are placed at low figures, 10, 12, 14, 16, 18 bushels per acre. The resulting regulating price of production is 6 shillings per bushel.

The following 13 tables correspond to the three cases of differential rent No. II, with an additional investment of a capital of 50 shillings per acre upon the same soil, with a constant, falling and rising price of production. Every one of these cases, again, is represented as it turns out, 1) with a constant, 2) with a falling, 3) with a rising productivity of the second investment of capital as compared to the first. This results furthermore in a few other cases, which are presented separately.

In case I, with a constant price of production, we have:

Variant No. 1: The productivity of the second investment of capital remains the same (Table XII.)

Variant No. 2: The productivity declines. This can take place only when soil A receives no second investment of capital, and it may take place in such a way that

the soil B likewise produces no rent (Table XIII), or,

the soil B does not lose all rent (Table XIV).

Variant No. 3: The productivity increases. (Table XV.) This case likewise excludes a second investment of capital upon soil A.

In case II, with a falling price of production, we have:

Variant No. 1: The productivity of the second investment of capital remains the same (Table XVI).

Variant No. 2: The productivity declines (Table XVII). These two variants are conditioned upon the throwing of soil A out of competition, and soil B producing no rent and regulating the price of production.

Variant No. 3: The productivity increases (Table XVIII). In this case the soil A remains the regulator.

In case III, with a rising price of production, two eventualities are possible; soil A may remain without rent and regulate the price, or, an inferior class of soil than A enters into competition and regulates the price, in which case A produces a rent.

First eventuality: Soil A remains the regulator.

Variant No. 1: The productivity of the second investment remains the same (Table XIX). This will happen under the conditions assumed by us only when the productivity of the first investment decreases.

Variant No. 2: The productivity of the second investment decreases (Table XX). This does not exclude the possibility that the first investment may retain the same productivity.

Variant No. 3: The productivity of the second investment (Table XIX) increases; this, again, presupposes a falling productivity of the first investment.

Second eventuality: An inferior quality of soil (designated as a) enters into competition; soil A yields a rent.

Variant No. 1: The productivity of the second investment remains the same (Table XXII).

Variant No. 2: The productivity declines (Table XXIII).

Variant No. 3: The productivity increases (Table XXIV).

These three variants appear under the general conditions of the problem and require no further remarks.

We herewith produce the Tables.

lf0445-03-0835-t0001.gif

When a second investment is placed upon the same soil, we have the following eventualities:

First Case: The Price of production remains unaltered.

Variant No. 1: The productivity of the second investment remains the same.

lf0445-03-0835-t0002.gif

Variant No. 2: The productivity of the second investment of capital declines; soil A receives no second investment.

If soil B ceases to yield a rent.

lf0445-03-0835-t0003.gif

If soil B does not lose all the rent.

lf0445-03-0836-t0001.gif

Variant No. 3: The productivity of the second investment of capital increases; no second investment upon soil A.

lf0445-03-0836-t0002.gif

Second case: The price of production declines.

Variant No. 1: The productivity of the second investment of capital remains the same. Soil A is thrown out of competition, soil B loses its rent.

lf0445-03-0836-t0003.gif

Variant No. 2: The productivity of the second investment of capital declines; soil A is thrown out of competition, soil B loses its rent.

lf0445-03-0837-t0001.gif

Variant No. 3: The productivity of the second investment of capital increases; soil A remains in the competition. Soil B produces rent.

lf0445-03-0837-t0002.gif

Third Case: The price of production rises.

If soil A remains without rent and continues to regulate the price.

Variant No. 1: The productivity of the second investment of capital remains the same; this implies a decreasing productivity of the first investment of capital.

lf0445-03-0837-t0003.gif

Variant No. 2: The productivity of the second investment of a capital decreases; this does not exclude a constant productivity of the first investment.

lf0445-03-0838-t0001.gif

Variant No. 3: The productivity of the second investment of capital rises, which implies, under the assumed conditions, a declining productivity of the first investment.

lf0445-03-0838-t0002.gif

If an inferior soil (designated as a) becomes the regulator of prices and soil A produces a rent. This admits of a constant productivity of the second investment in the case of all variants.

Variant No. 1: The productivity of the second investment of capital remains the same.

lf0445-03-0838-t0003.gif

Variant No. 2: The productivity of the second investment of capital declines.

lf0445-03-0839-t0001.gif

Variant No. 3: The productivity of the second investment increases.

lf0445-03-0839-t0002.gif

These tables lead to the following conclusions:

In the first place they show that the series of rents maintains the same proportions as the series of degrees of fertility, taking the rentless regulating soil as the zero point. Not the absolute yields, but only the differences in yield are the determining elements of rent. Whether the different kinds of soil produce 1, 2, 3, 4, 5 bushels, or whether they produce 11, 12, 13, 14, 15, bushels of yield per acre, the rents are in both cases seriatim 0, 1, 2, 3, 4, bushels, or money to that amount.

But the result of our analysis is far more important with respect to the total yields of rent with a repeated investment of capital upon the same soil.

In five cases out of the analysed thirteen the total amount of the rents is doubled with the duplication of the investment of capital; instead of 10 times 12 shillings it becomes 10 times 24 shillings, or 240 shillings. These cases are:

Case I, constant price, Variant No. 1, the increase of productivity remaining the same (Table XII).

Case II, falling price, Variant No. III: increasing expansion of production (Table XVIII).

Case III, increasing price, first eventuality, where soil A remains the regulator, in all three Variants (Tables XIX, XX, and XXI).

In four cases the rent increases by more than double, namely:

Case I, Variant No. III, constant price, increasing expansion of production (Table XV). The amount of the rent rises to 330 shillings.

Case III, second eventuality, where soil A produces a rent, in all three variants (Table XXII, rent 15 times 30 = 450 shillings; Table XXIII, rent 5

times 20 plus 10 times 28 = 380 shillings; Table XXIV, rent 5 times 15 plus 15 times $33 \frac{1}{3}$ = 581¼ shillings).

In one case the rent rises, but not to double the amount of the rent produced by the first investment of capital:

Case I, constant price, Variant II: falling productivity of the second investment, under conditions, in which B does not wholly lose its rent (Table XIV, rent 4 times 6 plus 6 times 21 = 150 shillings).

Finally, it is only in three cases that the total rent, with a second investment upon all kinds of soil, remains at the same level as with the first investment (Table XI); these are the cases, in which the soil A is thrown out of competition and soil B becomes the regulator and pays no rent. In this case the rent B is not only lost, but is also deducted from every succeeding link of the rent series. This is the basis of the above result. We mean the following cases:

Case I, Variant II, when the conditions are such that soil A is eliminated (Table XIII). The sum of the rent is six times twenty, or $10 \times 12 = 120$, as in Table XI.

Case II, Variants I and II. Here soil A is necessarily eliminated, according to the assumption (Tables XVI and XVII) and the sum of the rent is again $6 \times 20 = 10 \times 12 = 120$ shillings.

This is to say: In the great majority of all possible cases the rent rises, both per acre of the rent paying soils and for the total amount, as a result of an increased investment of capital upon the land. Only in three cases out of the thirteen analysed cases the total amount of the rent remains unaltered. These are the cases, in which the lowest quality of soil, which hitherto paid no rent, drops out of competition and the next higher one takes its place and loses its rent. But even in these cases do the rents upon the superior soils rise in comparison to the rents due to the first investment. When the rent of C falls from 24 to 20, then that of D and E rises from 36 to 48 respectively to 40 and 60 shillings.

A fall of the total rents below the level of the first investment of capital (Table XI) would be possible only in the case that soil B as well as soil A would drop out of competition and soil C become regulating and rentless.

The more capital is applied to a certain soil, and the higher the development of agriculture and of civilization in general is in a certain country, the more do the rents rise per acre and per total amount of rental, and the more immense becomes the tribute paid by society to the great land owners in the form of surplus profits — so long as the different soils taken under cultivation remain capable of competition.

This law explains the wonderful vitality of the class of great landlords. No social class lives so sumptuously, no other claims like it a right to a traditional luxury in keeping with its “estate,” regardless of where the money for that purpose may come from, no other class piles debt upon debt as lightheartedly as it. And yet it always lands on its feet — thanks to the capital invested by other people in the soil, whereby the landlord collects a rent, which stand in no proportion to the profits to be drawn out of the soil by the capitalist.

However, the same law also explains, why the vitality of the great landlord is gradually exhausted.

When the English corn taxes were abolished in 1846, the English manufacturers believed that they had transformed the landowning aristocracy into paupers. Instead of that they became richer than ever. How did that happen? Very simple. In the first place, the renting capitalists were now compelled by contract to invest 12 pounds sterling annually instead of 8 pounds, as heretofore. And in the second place, the landlords, being strongly represented also in the Lower House, granted to themselves a heavy subsidy for the drainage and other permanent improvements of their lands. Since no total displacement of the worst soil took place, but at the worst a temporary employment of such soil for other purposes, the rents rose in proportion to the increased investment of capital, and the landed aristocracy were better off than ever before.

But everything is perishable. The transoceanic steamboats and the railroads of North and South America and India enabled very peculiar masses of land to enter into competition upon the European grain markets. There were on the one hand the North American prairies, the Argentine pampas, steppes, made fertile for the plow by nature itself, virgin soil, which offered rich harvest for years to come even with a primitive cultivation and without any fertilization. Then there were the lands of the Russian and Indian communes, that had to sell a portion of their product, and an increasing one at that, for the purpose of obtaining money for the taxes wrung from them by the pitiless despotism of the state, very often by means of torture. These products were sold without regard to their cost of production, sold at the price offered by the dealer, because the peasant had to have money under all circumstances when tax paying day came around. And against the competition of the virgin prairie soils and of the Russian and Indian peasants ground down by taxation, the European capitalist farmer and peasant could not stand up at the old rents. A portion of the soil of Europe fell definitely out of the competition for the raising of grain, the rents fell everywhere. Our second case Variant II (falling prices and falling productivity of the additional investment of capital) became the rule for Europe. This accounts for the woes of the landlords from Scotland to Italy, and from Southern France to Eastern Prussia. Fortunately all prairie lands have not been taken under cultivation. There are enough of them left to ruin all the great landlords of Europe and the small ones into the bargain. — F. E.]

The heads, under which rent is to be analyzed, are the following:

Differential rent.

Meaning of differential rent. Illustration by water power. Transition to real agricultural rent.

Differential rent No. I, arising from different fertilities of different pieces of land.

Differential rent No. II, arising from successive investments of capital upon the same soil. Differential rent No. II is to be analysed

with a stationary price of production.

with a falling price of production.
with a rising price of production.

And furthermore

the transformation of surplus profit into rent.
Influence of this rent upon the rate of profit.

Absolute rent.
The price of land.
Final Remarks concerning ground rent.

As the general result of our analysis of differential rent we come to the following conclusions:

The formation of surplus profits may take place in different ways. On the one hand it may come about by the help of differential rent No. I, that is, by an investment of the entire agricultural capital upon one soil area consisting of soils of different fertilities. Or, it may come about by means of differential rent No. II, that is by means of the varying differential productivity of successive investments of capital upon the same soil, which signifies here a greater productivity, say in wheat measured by quarters, than is secured with the same investment of capital upon the worst rentless soil, which regulates the price of production. But no matter how these surplus profits may arise, their transformation into rents, their transfer from the capitalist farmer to the landlord, always presupposes that the various individual prices of production represented by the partial products of the individual capitals invested in succession (independently of the general price of production by which the market is regulated) have previously been reduced to an individual average price of production. The excess of the general regulating price of production of the product of one acre over its individual average price, forms and measures the rent per acre. In differential rent No. I the differential results may be distinguished by themselves, because they take place upon differentiated portions of land lying side by side, with an investment of capital and a degree of cultivation considered normal per acre. In differential rent No. II they must first be made distinguishable; they must in fact be reconverted into differential rent

No. I, and this cannot take place in any other but the indicated way. Take for instance Table III, Chapter XLI, 3.

Soil B gives for the first investment of capital $2\frac{1}{2}$ pounds sterling 2 quarters per acre, and for the second equally large one $1\frac{1}{2}$ quarters; together $3\frac{1}{2}$ quarters upon the same acre. These $3\frac{1}{2}$ quarters do not show what part of them is a product of the investment of capital No. I and what part a product of capital No. II, for they are all grown upon the same soil. They are in fact the product of the total capital of 5 pounds sterling; and the actual condition of the matter is that a capital of $2\frac{1}{2}$ pounds sterling produced 2 quarters, and a capital of 5 pounds sterling produced only $3\frac{1}{2}$ quarters, not 4 quarters. The case would be just the same, if these 5 pounds sterling were producing 4 quarters, so that the proceeds of both investments of capital would be the same, or even 5 quarters, so that the second investment of capital would yield a surplus of 1 quarter. The price of production of the first 2 quarters is $1\frac{1}{2}$ pounds sterling per quarter, and that of the second $1\frac{1}{2}$ quarters is 2 pounds sterling per quarter. Consequently the $3\frac{1}{2}$ quarters together cost 6 pounds sterling. This is the individual price of production of the total product, and it makes an average of 1 pound and $14\frac{2}{7}$ shillings per quarter, in round figures $1\frac{3}{4}$ pounds sterling. With the average price of production regulated by soil A, namely 3 pounds sterling, this makes a surplus profit of $1\frac{1}{4}$ pounds sterling per quarter, and for the total $3\frac{1}{2}$ quarters profit of $4\frac{3}{8}$ pounds sterling. With the average price of production of B this is represented by about $1\frac{1}{2}$ quarters. In other words, the surplus profit of B is represented by an aliquot portion of the product of B, by these $1\frac{1}{2}$ quarters, which express the rent in terms of grain, and which under the prevailing price of production sell at $4\frac{1}{2}$ pounds sterling. But on the other hand, the surplus product of one acre of B compared to that of A is not without ceremony a formation of surplus profit, is not offhand a surplus product. According to our assumption one acre of B produces $3\frac{1}{2}$ quarters, whereas one acre of A produces only 1 quarter. The surplus of the product of B is, therefore, $2\frac{1}{2}$ quarters, but the surplus product is only $1\frac{1}{2}$ quarters; for the capital invested in B is twice that of A, and for this reason its cost of production is doubled. If soil A should also receive an investment of 5 pounds sterling, and the rate of productivity should remain the same, then the product would amount to 2 quarters instead of 1 quarter, and it would then be seen that the actual surplus product is found, not by a comparison of

$3\frac{1}{2}$ with 1, but of $3\frac{1}{2}$ with 2, so that it would be only $1\frac{1}{2}$ quarter, not $2\frac{1}{2}$ quarters. Furthermore, if B should invest a third capital of $2\frac{1}{2}$ pounds sterling, which would produce only 1 quarter, so that this quarter would cost 3 pounds sterling, the same as that of A, then its selling price would cover only the cost of production, would yield only the average profit, but not a surplus profit, and would not offer anything that could be converted into rent. The product per acre of any kind of soil, compared with the product per acre of soil A, shows neither whether it is a product of the same or of a larger investment of capital, nor whether the additional product covers merely the price of production, nor whether it is due to a greater productivity of the additional capital.

With a decreasing rate of productivity of the additional investments of capital, whose limits, so far as the new formation of surplus profit is concerned, is that investment of capital which just covers the cost of production, in other words, which produces one quarter at the same expense as the same investment of capital in one acre of soil A, amounting to 3 pounds sterling according to our assumption, we come to the following conclusions on the basis of what has gone before: That the limit, where the total investment of capital in one acre of B would not yield any more rent, is reached when the individual average price of production of the product per acre of B would rise to the price of production per acre of A.

If B invests only such additional capital as pays just the price of production, but forms no surplus profit, no rent, then this raises only the individual average price of production per quarter, but does not affect the surplus profit, or eventually the rent, formed by previous investments of capital? For the average price of production always remains under that of A, and when the excess over the price per quarter decreases, then the number of quarters increases in the same ratio, so that the total excess over the price remains unaltered.

In the case assumed, the first two investments of capital of 5 pounds sterling produce $3\frac{1}{2}$ quarters upon B, which amounts to $1\frac{1}{2}$ quarters of rent, at $4\frac{1}{2}$ pounds sterling, according to our assumption. Now, if a third investment of capital of $2\frac{1}{2}$ pounds sterling is added, which produces only one additional quarter, then the total price of production (including a profit

of 20%) of the $4\frac{1}{2}$ quarters is 9 pounds sterling, so that the average price per quarter is 2 pounds sterling. The average price of production per quarter upon B has then risen from $1\frac{5}{7}$ pounds sterling to 2 pounds sterling, so that the surplus profit per quarter, compared with the regulating price of A, has fallen from $1\frac{2}{7}$ pounds sterling to 1 pound sterling. But $1 \times 4\frac{1}{2} = 4\frac{1}{2}$ pounds sterling, just as formerly $1\frac{2}{7} \times 3\frac{1}{2} = 4\frac{1}{2}$ pounds sterling.

upon B, and that these investments produce one quarter only at its average price of production, then the total product per acre would be $6\frac{1}{2}$ quarters, and their cost of production 15 pounds sterling. The average price of production per quarter of B would have risen once more, from 1 pound sterling to $2\frac{4}{13}$ pound sterling, and the surplus profit per quarter, compared with the regulating price of production of A, would have dropped once more, from 1 pound sterling to $\frac{9}{13}$ pound sterling. But these $\frac{9}{13}$ would now have to be calculated upon $6\frac{1}{2}$ quarters instead of $4\frac{1}{2}$ quarters. And $\frac{9}{13} \times 6\frac{1}{2} = 1 \times 4\frac{1}{2} = 4\frac{1}{2}$ pounds sterling.

The inference from this is, in the first place, that no raising of the regulating price of production is necessary under these circumstances, in order to make possible additional investments of capital even to the point where the additional capital ceases wholly to produce any surplus profit and yields only the average profit. It follows furthermore that the sum of the surplus profit per acre remains the same here, no matter how much the surplus profit per quarter may decrease; this decrease is always balanced by a corresponding increase of the quarters produced per acre. In order that the average price of production may rise to the general price of production (in this case to 3 pounds sterling for soil B) it is necessary that additions should be made to the capital, which must have a product of a higher price of production than the regulating one of 3 pounds sterling. But we shall see that this does not suffice without further ado in order to raise the average price of production per quarter of B to the general price of production of 3 pounds sterling.

Let us assume that soil B produced.

$3\frac{1}{2}$ quarters as before at a price of production of 6 pounds sterling; this with two investments of capital of $2\frac{1}{2}$ pounds sterling each, which both

form surplus profits, but of a decreasing amount.

1 quarter at 3 pounds sterling; an investment of capital, in which the individual price of production shall be equal to the regulating price of production.

1 quarter at 4 pounds sterling; an investment of capital, in which the individual price of production shall be higher by 25% than the regulating price.

We should then have $5\frac{1}{2}$ quarters per acre, at 13 pounds sterling, with an investment of a capital of 10 pounds sterling; this would be four times the original investment of capital, but not quite three times the product of the first investment of capital.

$5\frac{1}{2}$ quarters per acre at 13 pounds sterling make an average price of production of $2\frac{4}{11}$ pounds sterling, which would give a surplus of $\frac{7}{11}$ pound per quarter at the regulating price of production of 3 pounds sterling. This surplus may be converted into rent. $5\frac{1}{2}$ quarters sold at the regulating price of production of 3 pounds sterling make $16\frac{1}{2}$ pounds sterling. After deducting the cost of production of 13 pounds sterling a surplus, or rent of $3\frac{1}{2}$ pounds sterling remains, which, calculated at the present average price of production per quarter of B, that is, at $2\frac{4}{11}$ pounds per quarter, represent $1\frac{5}{72}$ quarters. The money rent would have fallen by 1 pound sterling, the grain rent by about $\frac{1}{2}$ quarter, but in spite of the fact that the fourth additional investment upon B does not produce a surplus profit, but even less than the average profit, a surplus profit and a rent still continue to exist. Let us assume that not only the investment of capital as illustrated in No. 3), but also that in No. 2), produce at a cost exceeding the regulating price of production, then the total production is $3\frac{1}{2}$ quarters at 6 pounds sterling plus 2 quarters at 8 pounds sterling, total $5\frac{1}{2}$ quarters at 14 pounds sterling cost of production. The average price of production per quarter would be $2\frac{6}{11}$ pounds sterling, and it would leave a surplus of $\frac{5}{11}$ pound sterling. The $5\frac{1}{2}$ quarters, sold at 3 pounds sterling, make $16\frac{1}{2}$ pounds sterling; subtract the 14 pounds sterling of cost of production, and $2\frac{1}{2}$ pounds sterling remain for rent. At the present average price of production

upon B this would be equivalent to $\frac{55}{56}$ quarters. In other words, a rent would still remain, although less than before.

This shows at any rate, that upon the better soils with additional investments of capital, whose product costs more than the regulating price of production, the rent does not disappear, at least not within the bounds of admissible practice, although it must decrease, and will do so in proportion, on the one hand, to the aliquot part formed by this unproductive capital in the total investment of capital, on the other hand in proportion to the decrease of its fertility. The average price of its fertility would still stand below the regulating price and would still leave a surplus profit that could be converted into rent.

Let us now assume that the average price per quarter of B coincides with the general price of production, in consequence of four successive investments of capital ($2\frac{1}{2}$, $2\frac{1}{2}$, 5 and 5 pounds sterling) with a decreasing productivity.

lf0445-03-0849-t0001.gif

The capitalist renter in this case sells every quarter at its individual price of production, and consequently the total number of quarters at their average price of production per quarter, which coincides with the regulating price of 3 pounds sterling. Hence he still makes a profit of 20%, or 3 pounds sterling, upon his capital of 15 pounds sterling. But the rent is gone. What has become of the surplus in this compensation of individual prices of production per quarter with the general price of production?

The surplus profit on the first $2\frac{1}{2}$ pounds sterling was 3 pounds sterling; on the second $2\frac{1}{2}$ pounds sterling it was $1\frac{1}{2}$ pounds sterling; total surplus profit on one-third of the invested capital, that is, on 5 pounds sterling, $4\frac{1}{2}$ pounds sterling, or 90%.

In the case of investment No. 3) the 5 pounds sterling do not only yield no surplus profit, but its product of $1\frac{1}{2}$ quarters, if sold at the general price of production, gives a minus of $1\frac{1}{2}$ pounds sterling. Finally, in the case of investment No. 4), which amounts likewise to 5 pounds sterling, its product of 1 quarter, if sold at the general price of production, gives a minus of 3

pounds sterling. Both investments of capital together give a minus of $4\frac{1}{2}$ pounds sterling, equal to the surplus profit of $4\frac{1}{2}$ pounds sterling, which was realized on investments Nos. 1) and 2).

The surplus profits and deficits balance one another. Therefore the rent disappears. In fact this is possible only because the elements of surplus-value, which form a surplus profit, or rent, now pass into the formation of the average profit. The capitalist renter makes this average profit of 3 pounds sterling on 15 pounds sterling, or of 20%, at the expense of the rent.

The compensation of the individual average price of production of B to the general price of production A, which regulates the market, presupposes that the difference, by which the individual price of the product of the first investment of capital stands below the regulating price, is more and more compensated and finally balanced by the difference, by which the product of the subsequent investments of capital stands above the regulating price. What appears as a surplus profit, so long as the product of the first investment of capitals sold by itself, becomes by degrees a part of their average price of production, and thereby enters into the formation of the average profit, until it is finally absorbed in this way.

If only 5 pounds sterling are invested in B, instead of 15 pounds sterling, and if the additional $2\frac{1}{2}$ quarters of the last Table are produced by taking $2\frac{1}{2}$ new acres of A under cultivation with an investment of $2\frac{1}{2}$ pounds sterling per acre, then the invested additional capital would amount only to $6\frac{1}{4}$ pounds sterling, so that the total investment on A and B for the production of these 6 quarters would be only $11\frac{1}{4}$ pounds sterling instead of 15 pounds sterling, and the total cost of production of these including the profit of $13\frac{1}{2}$ pounds sterling. The 6 quarters would still be sold at 18 pounds sterling, but the investment of capital would have decreased by $3\frac{3}{4}$ pounds sterling, and the rent upon B would be $4\frac{1}{2}$ pounds sterling per acre, as before. It would be different, if the production of additional $2\frac{1}{2}$ quarters would require that inferior soil than A, for instance A — 1, A — 2, should be taken under cultivation; so that the price of production per quarter, for $1\frac{1}{2}$ quarters on soil A — 1 would be 4 pounds sterling, and for the last quarter on soil A — 2 would be 6 pounds sterling. In this case these 6 pounds sterling would be the regulating price of production per quarter. The

3½ quarters of B would then be sold at 21 pounds sterling instead of 10½ pounds sterling, and this would leave a rent of 15 pounds sterling instead of 4½ pounds sterling, or in grain a rent of 2½ quarters instead of 1½ quarter. In the same way the one quarter on A would now leave a rent of 3 pounds sterling, or of ½ quarter.

Before we discuss this point any further, we will pause to make the following observation.

The average price of one quarter of B is compensated and coincides with the general price of production of 3 pounds sterling per quarter, regulated by A, as soon as that portion of the total capital, which produces the excess of 1½ quarter, is balanced by that portion of the total capital, which produces a deficit of 1½ quarter. How soon this compensation is effected, or how much capital with less than average productivity must be invested in B for that purpose, will depend, assuming the surplus productivity of the first investments of capital to be given, upon the relative underproductivity of the later invested capitals, compared with an investment of the same amount upon the worst regulating soil A, or upon the individual price of production of their product, compared with the regulating price.

We now come to the following conclusions from the foregoing:

So long as the additional capitals are invested in the same soil with a surplus productivity, even a decreasing one, the absolute rent in grain and money increases per acre, although it decreases relatively, in proportion to the advanced capital (in other words, the rate of surplus profit, or rent). The limit is here formed by that additional capital, which yields only the average profit, or the price of production of whose product coincides with the general price of production. The price of production remains the same under these circumstances, unless the production upon the lesser soils becomes superfluous through an increased supply. Even with a falling price may these additional capitals still produce a surplus profit, though a smaller one, within certain limits.

The investment of additional capital, which produces only the average profit, whose surplus productivity is therefore zero, does not alter anything

in the level of the existing surplus profit, and consequently of the rent. The individual average price per quarter increases thereby upon the superior soils; the surplus per quarter decreases, but the number of quarters, which carry this decreased surplus, increases, so that the product remains the same.

Additional investments of capital, whose product has an individual price of production exceeding the regulating price, whose surplus productivity is therefore not merely zero, but less than zero, that is, a minus lower than the productivity of the same investment of capital upon the regulating soil A, bring the individual average price of production of the total product of the superior soil closer to the general price of production, reduce more and more the difference between both, which forms the surplus profit, or rent. More and more of that which forms a surplus profit, or rent, passes over into the formation of the average profit. But nevertheless the total capital invested in one acre of B continues to yield a surplus profit, although a decreasing one in proportion as the capital with undernormal productivity and the degree of its underproductivity increase. The rent, with an increasing capital and increasing production, decreases in this case absolutely per acre, not merely relatively as compared to the increasing size of the invested capital, as in the second case.

The rent cannot disappear, unless the individual average price of production of the total product of the better soil B coincides with the regulating price, so that the entire surplus profit of the first more productive investment of capital is consumed in the formation of the average profit.

The minimum limit of the fall for the rent per acre is the point at which it disappears. But this point does not assert itself, as soon as the additional investments of capital work with an underproductivity, but rather as soon as the additional investment of the underproductive capitals becomes so great that their effect paralyzes the overproductivity of the first investments of capital, so that the productivity of the total capital becomes the same as that of A, and the individual average price of the quarter of B the same as that of the quarter of A.

In this case, likewise, the regulating price of production, 3 pounds sterling per quarter, remains the same, although the rent would have disappeared. Only after this point would have been passed, would the price of production have to rise in consequence of an increase of either the degree of underproductivity of the additional capital or of the magnitude of the additional capital of the same underproductivity. For instance, if in the above Table $2\frac{1}{2}$ quarters were produced instead of $1\frac{1}{2}$ quarters, at 4 pounds sterling per quarter, upon the same soil, then we should have altogether 7 quarters at 22 pounds sterling cost of production; the quarter would cost $3\frac{1}{7}$ above the general price of production which would have to rise.

For a long time, then, additional capital with underproductivity, or even increasing underproductivity, might be invested, until the individual average price per quarter of the best soils would become equal to the general price of production, until the excess of the latter over the former, and with it the surplus profit and the rent, would entirely disappear.

And even in this case the disappearance of the rent from the better kinds of soil would only signify that the individual average price of their products would coincide with the general price of production, so that this last price would not have to rise.

In the above illustration, upon soil B, which is there the lowest of the better rent paying soils, $3\frac{1}{2}$ quarters were produced by a capital of 5 pounds sterling with a surplus productivity, and $2\frac{1}{2}$ quarters by a capital of 10 pounds sterling with underproductivity, together 6 quarters, of which $\frac{5}{12}$ are produced by the capitals with underproductivity. And only at this point does the individual average price of production of the 6 quarters rise to 3 pounds sterling and coincide with the general price of production.

Under the law of landed property, however, the last $2\frac{1}{2}$ quarters could not have been produced in this way at 3 pounds sterling per quarter, with the exception of the case, in which they may be produced upon $2\frac{1}{2}$ new acres of the soil A. The case, in which the additional capital produces only at the general price of production, would have been the limit. Beyond it the additional investment of capital would have to cease upon the same soil.

If the capitalist renter once pays $4\frac{1}{2}$ pounds sterling of rent for the first two investments of capital, he must continue to pay them, and every investment of capital, which produces one quarter below 3 pounds sterling, would cause him a deduction from his profit. The compensation of the individual price of production, in the case of underproductivity, is thereby prevented.

Let us take this case in the previous illustration, in which the price of production of the soil A, at 3 pounds sterling per quarter, regulates the price for B.

lf0445-03-0854-t0001.gif

The cost of production of the $3\frac{1}{2}$ quarters in the first two investments is likewise 3 pounds sterling per quarter for the capitalist renter, since he has to pay a rent of $4\frac{1}{2}$ pounds sterling, the difference between his individual price of production and the general price of production not flowing into his pocket. In his case, then, the excess of the price of the first two investments of capital cannot serve for the compensation of the deficit incurred in the production of the third and fourth investment of capital.

The $1\frac{1}{2}$ quarters in investment No. 3) cost the capitalist renter, with profit included, 6 pounds sterling; but at the regulating price of 3 pounds sterling per quarter he can sell them only for $4\frac{1}{2}$ pounds sterling. In other words, he would not only lose his whole profit, but also $\frac{1}{2}$ pound sterling, or 10% of his invested capital of 5 pounds sterling. The loss of profit and capital in the case of investment No. 3) would amount to $1\frac{1}{2}$ pound sterling, and in the case of investment No. 4) 3 pounds sterling, together $4\frac{1}{2}$ pounds sterling, just as much as the rent of the better investments amounts to, whose individual price of production cannot take part in the compensation of the individual average price of production of the total product of B, because its surplus is paid as a rent to some third person.

If the demand should require that the additional $1\frac{1}{2}$ quarters must be produced by a third investment of capital, then the regulating market price would have to rise to 4 pounds sterling per quarter. In consequence of this rise in the regulating market price the rent upon B would rise for the first and second investment, and a rent would be formed upon A.

Although the differential rent is but a formal transformation of surplus profit into rent, since property in land enables the owner in this case to draw the surplus profit of the capitalist render into his own hands, we find nevertheless that the successive investment of capital upon the same land, or, what amounts to the same, the increase of the capital invested in the same land, reaches its limit far more rapidly when the rate of productivity of the capital decreases and the regulating price remains the same, so that in fact a more or less artificial barrier is erected as a consequence of the mere formal transformation of surplus profit into ground rent, — which is the result of private property in land. The rise of the general price of production, which becomes necessary when the limit is narrowed beyond the ordinary, is in this case not merely the cause of a rise of the differential rent, but the existence of differential rent as rent is at the same time a reason for the earlier and more rapid rise of the general price of production, in order to insure by this means the supply of the needed larger product.

Furthermore we must make a note of the following facts:

By an addition of capital to soil B the regulating price could not, as above, rise to 4 pounds sterling, if soil A should supply the additional product below 4 pounds sterling by a second investment of capital, or if new and worse soil than A should come into competition, whose price of production would be higher than 3 but lower than 4 pounds sterling. We see, then, that differential rent No. I and differential rent No. II, while the first is the basis of the second, are at the same time mutual limits for one another, by which now a successive investment of capital upon the same soil, now an investment of capital side by side upon new soil, is brought about. In like manner they act as mutual boundaries in other cases, for instance, when better land is taken up.

CHAPTER XLIV. DIFFERENTIAL RENT EVEN UPON THE WORST SOIL UNDER CULTIVATION.

LET us assume that the demand for grain is rising, and that the supply cannot be made to cover the demand, unless successive investments of capital with deficient productivity are made upon the rent-paying soils, or by an additional investment of capital, likewise with a decreasing productivity, upon soil A, or by the investment of capital in new lands of a lesser quality than A.

Let us take soil B as a representative of the rent paying soils.

The additional investment of capital demands a rising of the market price above the prevailing price of production of 3 pounds sterling per quarter, in order that the increased production of one quarter (which may here stand for one million quarters, as may every acre for one million acres) upon B may be possible. An increased production may also take place upon soils C and D, etc., the soils paying the highest rent, but only with a decreasing power to produce a surplus; but it is assumed that the one quarter upon B must necessarily be produced in order to cover the demand. If this one quarter is more easily produced by investing more capital in B than with the same addition of capital to A, or by descending to soil A — 1, which may, perhaps, produce one quarter only for 4 pounds sterling, whereas the additional capital upon A might do so at $3\frac{3}{4}$ pounds sterling per quarter, then the additional capital upon B will regulate the market price.

Let us also assume that A produces one quarter at 3 pounds sterling, as it did heretofore. Let B likewise, as before, produce altogether $3\frac{1}{2}$ quarters at an individual price of production of 6 pounds sterling for its total output. Now, if an addition of 4 pounds sterling becomes necessary upon B (including the profit) in order to produce an additional quarter, whereas it might be produced upon A at $3\frac{3}{4}$ pounds sterling, then it would naturally be produced upon A, not upon B. Let us assume, then, that this additional

quarter can be produced upon B with an additional cost of production of $3\frac{1}{2}$ pounds sterling. In this case $3\frac{1}{2}$ pounds sterling would become the regulating price for the entire production. B would now sell its product of $4\frac{1}{2}$ quarters at $15\frac{3}{4}$ pounds sterling. The cost of production of the first $3\frac{1}{2}$ quarters, or 6 pounds sterling, would have to be deducted from this, also that of the last quarter, or $3\frac{1}{2}$ pounds sterling, total $9\frac{1}{2}$ pounds sterling. This leaves a surplus profit for rent of $6\frac{1}{4}$ pounds sterling, as against the former $4\frac{1}{2}$ pounds sterling. In this case one acre of A would also yield a rent of $\frac{1}{2}$ pound sterling; but not the worst soil A, but the better soil B would regulate the price of production with $3\frac{1}{2}$ pounds sterling. Of course we assume here that new soil of the quality of A is not accessible in the same favorable location as that hitherto cultivated, but that either a second investment of capital upon the already cultivated soil A is required at a higher cost of production, or the cultivation of still inferior soil, such as A — 1. As soon as differential rent No. II comes into action by successive investments of capital, the limits of the rising price of production may be regulated by better soil, and the worst soil, the basis of differential rent No. I, may also carry a rent. Under these circumstances all cultivated lands would pay a rent under a mere differential rent system. We should then have the following two Tables, in which we mean by the term cost of production the sum of the invested capital plus 20% profit, in other words, on every $2\frac{1}{2}$ pounds sterling of capital $\frac{1}{2}$ pound sterling of profit, total 3 pounds sterling.

lf0445-03-0858-t0001.gif

This is the condition of affairs, before the new capital of $3\frac{1}{2}$ pounds sterling is invested in B, which supplies only one quarter. After this investment has been made, we have the following condition:,

lf0445-03-0858-t0002.gif

[This, again, is not quite correctly calculate. The capitalist renter of B has to meet a cost of production of $9\frac{1}{2}$ pounds sterling for the $4\frac{1}{2}$ quarters and besides $4\frac{1}{2}$ pounds sterling in rent, a total of 14 pounds sterling; average per quarter $3\frac{1}{2}$ pounds sterling. This average price of his total production thus becomes the regulating market price. According to this the rent upon A would amount to $\frac{1}{9}$ pound sterling instead of $\frac{1}{2}$ pound sterling and that upon B would remain $4\frac{1}{2}$ pounds sterling, as heretofore. $4\frac{1}{2}$ quarters at $3\frac{1}{2}$ pounds sterling make 14 pounds sterling, and if we deduct

9½ pounds sterling of cost of production we have 4½ pounds sterling left for surplus profit. We see, then, that in spite of the required change in figures this illustration shows the way in which the better rent paying soil, by means of differential rent No. II, may regulate the price and thus transform all soil, even a hitherto rentless one, into rent paying soil. — F. E.]

The grain rent must rise, as soon as the regulating price of production of the grain rises, that is, as soon as the quarter of grain rises upon the regulating soil, or the regulating investment of capital upon one of the various kinds of soil. It is the same as though all kinds of soil had become less productive, and as though they were producing only 5-7 quarter instead of one quarter with a new investment of 2½ pounds sterling. Whatever they produce more in grain with the same investment of capital, is converted into a surplus product, in which the surplus profit and with it the rent are incorporated. Assuming that the rate of profit remains the same, the capitalist renter will have to buy less grain with his profit. The rate of profit may remain the same, if the wages do not rise, either because they are depressed to the physical minimum, below the normal value of labor-power, or because the other things needed for consumption by the laborer and supplied by the manufacturer have become relatively cheaper; or because the working day has been prolonged or has become more intensive, so that the rate of profit in other than agricultural lines of production, which, however, regulates the agricultural profit, has remained the same or has risen; or, finally, because there may be more constant and less variable capital employed in agriculture, even though the total capital invested be the same.

Now we have considered the first condition in which rent may arise upon the worst soil A without taking still worse soil under cultivation; that is, in which rent may arise out of the difference between the old individual price of this land, which was hitherto the regulating price of production, and the new, higher, price of production, at which the last additional capital with less than normal productive power upon the better soil supplies the necessary additional product.

If the additional product had to be supplied by soil A — 1, which cannot produce one quarter at less than 4 pounds sterling, then the rent would have risen to one pound sterling upon A. But in this case the soil A — 1 would have taken the place of A as the worst cultivated soil, and A would have risen in the scale to the place of the lowest link in the series of rent paying soils. Differential rent No. I would have changed. This case, then, is outside of the consideration of differential rent II, which arises out of the different productivity of successive investments of capital upon the same piece of land.

But aside from this, differential rent may arise upon soil A in two other ways.

In the first place, it may arise so long as the price remains unchanged (any price, even a lower one compared to former ones), if the additional investment of capital creates a surplus product, which it must always do, on first sight, and up to a certain point, upon the worst soil.

In the second place, it may arise, if the productivity of the successive investments of capital upon soil A decreases.

The assumption in either case is that the increased production is required on account of the condition of the demand.

But from the point of view of differential rent, a peculiar difficulty arises here on account of the previously developed law, according to which it is always the individual average price of production per quarter in the total production (or the total investment of capital) which acts as the determining factor. In the case of soil A, however, it is not, as it is in the case of the better soils, a question of a price of production existing outside of it, which limits the equalization of the individual price of production and the general price of production, for new investments of capital. For the individual price of production of A is precisely the general price of production regulating the market price.

Let us assume:

When productive power of successive investments of capital is increasing, that one acre of A will produce 3 quarters instead of 2 quarters with an investment of 5 pounds sterling of capital, corresponding to 6 pounds sterling of cost of production. The first investment of $2\frac{1}{2}$ pounds sterling supplies one quarter, the second 2 quarters. In this case 6 pounds sterling of cost of production will correspond to a product of 3 quarters, so that the average price of one quarter will be 2 pounds sterling. If the 3 quarters are sold at 2 pounds sterling per quarter, then A does not produce any rent any more than it did before. Only the basis of differential rent No. II has been altered. The regulating price of production is now 2 pounds sterling instead of 3 pounds. A capital of $2\frac{1}{2}$ pounds sterling produces now an average of $1\frac{1}{2}$ quarters upon the worst soil instead of 1 quarter, and this is now the official productivity for all better soils with an investment of $2\frac{1}{2}$ pounds sterling. A portion of the ordinary surplus product now passes over into the formation of their necessary product, just as a portion of their surplus profit now passes over into the formation of the average profit.

But if the calculation is made as it is upon the better soils, where the average calculation does not alter anything in the absolute surplus, because the general price of production is the limit of the investment of capital, then one quarter of the first investment of capital costs 3 pounds sterling and the 2 quarters of the second investment costs only $1\frac{1}{2}$ pounds sterling. This would give rise to a grain rent of one quarter and a money rent of 3 pounds sterling upon A, but the 3 quarters would be sold at the old price of 9 pounds sterling all together. If a third investment of $2\frac{1}{2}$ pounds sterling of capital were made at the same productivity as the second investment, then the total production would be 5 quarters at 9 pounds sterling of cost of production. If the individual average price of A should remain the regulating price, then one quarter would be sold at $1\frac{4}{5}$ pound sterling. The average price would have fallen once more, not through a new rise of the productivity of the third investment of capital, but merely through the addition of a new investment of capital with the same additional productivity as the second one. Instead of raising the rent upon the rent paying soils, the successive investments of capital of a higher, but sustained, fertility upon the soil A would lower the price of production and with it the differential rent upon all other soils in the same proportion, under conditions remaining the same. On the other hand, if the first investment of

capital, which produces one quarter at 3 pounds sterling, should remain in force by itself, then 5 quarters would be sold at 15 pounds sterling, and the differential rent of the later investments of capital upon soil A would amount to 6 pounds sterling. The additional capital per acre of soil A, whatever might be the manner of its application, would be an improvement in this case, and it would make the original portion of capital more productive. It would be nonsense to say that $\frac{1}{3}$ of the capital had produced one quarter and the other $\frac{2}{3}$ four quarters. For 9 pounds sterling per acre would always produce 5 quarters, while 3 pounds sterling would produce only one quarter. Whether a rent would arise here or not, whether a surplus profit would be made or not, would depend wholly upon circumstances. Normally the regulating price of production would fall. This would be the case, if this improved, but more expensive cultivation of soil A should take place only for the reason that it takes place upon all better soils, in other words, if a general revolution in agriculture should occur. And the assumption in that case would be that this soil is worked with 6 or 9 pounds sterling instead of 3 pounds. This would apply particularly, if the greater part of the cultivated acres of soil A, by which the bulk of the supply of this country is furnished, should be handled by this new method. But if the improvement should extend only to a small portion of the area of A, then this better cultivated portion would yield a surplus profit, which the landlord would be quick to transform wholly or in part into rent and fix permanently in the form of rent. In this way a rent might be gradually formed upon all soil of the A quality, in proportion as more and more of the area of this soil is taken under cultivation by the new method, and the surplus productivity might be confiscated wholly or in part, according to market conditions. The equalization of the price of production of soil A to the average price of its product at an increased investment might thus be prevented by the fixation of the surplus profit of this increased investment of capital in the form of rent. If so, this would be once again an illustration of the way in which the transformation of surplus profit into ground-rent, in other words, the intervention of property in land, raises the price of production, as we have already noticed in the case of the better soils upon which the productivity of the additional capitals decreased, so that here the differential rent would not be a mere result of the difference between the individual and the general price of production. It would prevent, in the case of soil A, the identification of both prices in one, because it would interfere

with the regulation of the price of production by the individual price of production of A. It would maintain a higher price of production than the necessary one and thus create a rent. Even if grain were freely imported from abroad, the same result could be brought about or perpetuated by compelling the tenants to use soil capable of competing in the raising of grain at the price of production regulated from abroad for other purposes, for instance for pastures, so that only rent paying soils could raise grain, that is, only soils whose individual average price of production per quarter would be below the price of production determined from abroad. On the whole it may be assumed that the price of production will fall, but not to the level of its average. Rather will it be higher than the average, but below the price of production of the worst cultivated soil A, so that the competition of new lands of the class A is held back.

When the productive power of the additional capitals is decreasing, let us assume that soil A — 1 can produce the additional quarter only at 4 pounds sterling, whereas soil A produces it at $3\frac{3}{4}$ pounds sterling, that is, more cheaply than the lesser soil, but still more dearly than the quarter produced by the first investment of capital upon it. In this case the total price of the two quarters produced upon A would be $6\frac{3}{4}$ pounds sterling, and the average price per quarter $3\frac{3}{8}$ pounds sterling. The price of production would rise, but only by $\frac{3}{8}$ pounds sterling, whereas it would rise by another $\frac{3}{8}$, or to $3\frac{3}{4}$ pounds sterling, if the additional capital were invested upon new soil, which could produce at $3\frac{3}{4}$ pounds sterling and thus bring about a proportional raise of all other differential rents.

The price of production of $3\frac{3}{8}$ pounds sterling per quarter of A would thus be brought to the figure of its average price of production with an increased investment of capital, and would be the regulating price; it would not yield any rent, because it would not produce any surplus profit.

However, if this quarter, produced by the second investment of capital, were sold at $3\frac{3}{4}$ pounds sterling, then the soil A would yield a rent of $\frac{3}{4}$ pound sterling, and it would do so upon all acres of A, even those with no additional investment of capital, which would still produce one quarter at 3 pounds sterling. So long as any uncultivated fields of A remain, the price could rise only temporarily to $3\frac{3}{4}$ pounds sterling. The competition of new

fields of A would hold the price of production at 3 pounds sterling, until all lands of the A class would be exhausted, whole favorable location would enable them to produce a quarter at less than $3\frac{3}{4}$ pounds sterling. This would be a likely assumption, although the landlord will not let any tenant have any land free of rent, if one acre of A pays rent.

It would depend once more upon the greater or smaller generalization of the second investment of capital in the available soil A, whether the price of production shall be brought down to an average or whether the individual price of production of the second investment of capital shall be regulating at $3\frac{3}{4}$ pounds sterling. This last case will take place only when the landlord gets time to fix the surplus profit, which would be made until the demand would be satisfied at the price of $3\frac{3}{4}$ pounds sterling, permanently in the form of rent.

Concerning the decreasing productivity of the soil with successive investments of capital, see Liebig. We have seen that the successive decrease of the surplus productive power of the investments of capital always increases the rent per acre, so long as the price of production remains the same, and this may take place even when the price of production is falling.

But in a general way the following remarks may be made.

From the point of view of the capitalist mode of production there is always a relative increase in the price of products, when a product cannot be secured unless an expense is incurred, a payment made, which did not have to be met formerly. For by a reproduction of the capital consumed in production we mean only the reproduction of values, which were represented by certain means of production. Natural elements passing into production as agencies, no matter what role they play in production, do not enter into the problem as parts of capital, but as free gifts of nature to capital, that is, as a free natural productivity of labor, which, however, appears as a productive power of capital, as do all other productive powers under the capitalist system. Therefore, if such a natural power, which originally does not cost anything, takes part in production, it does not count in the determination of prices, so long as the product supplied by its help

suffices for the demand. But if a larger product is demanded than that which can be supplied by the help of this natural power, so that the additional product must be created without this power, or by assisting it with human labor power, then a new additional element enters into capital. A relatively larger investment of capital is required for the purpose of securing the same product. All other circumstances remaining the same, the price of the product is raised.

(From a manuscript “Started about the Middle of February, 1876.”)

Differential Rent and Rent as a mere interest on capital invested in the soil.

The so-called permanent improvements — which change the physical, and in part also the chemical, condition of the soil by means of operations requiring an expenditure of capital, and which may be regarded as an incorporation of capital in the soil — nearly all amount to giving to a certain piece of land in a certain limited locality such qualities as are possessed by some other piece of land at some other locality, sometimes quite near to the other one, by nature. One piece of land is by nature level, another has to be leveled; one possesses natural drainage, another has to be drained artificially; one has naturally a deep top soil, another must be artificially deepened; one clay soil is naturally mixed with a proper modicum of sand, another has to be treated for the purpose of making it so; one meadow is irrigated or moistened naturally, another requires labor to get it into this condition, or in the language of bourgeois economists, it requires capital.

It is indeed a very exhilarating theory, which calls rent by the name of interest in the case of one piece of land, whose comparative advantages have been acquired, whereas it does not do so in the case of a piece of land which has the same advantages naturally. (As a matter of fact, this is distorted in practice into saying that because rent really coincides in the one case with interest, it must falsely be called interest in cases where this is positively not the case.) However, the land yields a rent after the investment of capital, not because capital has been invested, but because the investment of capital makes this land more productive than it was formerly. Assuming that all land requires this investment, then every piece of land which has not

received it must first pass through this stage, and the rent which the soil already endowed with capital yields (the interest which it may pay in a certain case), constitutes as much a differential rent as though it possessed this advantage by nature and the other land had to acquire it artificially.

This rent, which may be resolved into pure interest, becomes altogether a differential rent, as soon as the invested capital is sunk in the land. Otherwise the same capital would have to appear twice as capital.

It is one of the most amusing incidents, that all opponents of Ricardo, who combat the determination of value exclusively by labor, criticize in the case of differential rent arising from differences of soil the determination of value by nature instead of by labor. But at the same time they credit the location of the land with this determination, or perhaps, even more, the interest on capital sunk in the land during its cultivation. The same labor produces the same value in the product created during a certain time. But the magnitude, or the quantity, of this product, and consequently also that portion of value, which falls upon some aliquot part of this product, depends only upon the quantity of the product, so long as the quantity of labor is given, and the quantity of the product, in its turn, depends upon the productivity of the given quantity of labor, not upon the size of this quantity. It is immaterial, whether this productivity is due to nature or to society. Only in the case in which the productivity costs labor, and consequently capital, does it increase the cost of production by a new element, but this is not the case with nature alone.

CHAPTER XLV. ABSOLUTE GROUND-RENT.

IN the analysis of ground-rent we proceeded from the assumption, that the worst soil does not pay any ground-rent, or, to put it more generally, that only such land pays ground-rent as produces at an individual price of production which is below the price of production regulating the market, so that in this way a surplus profit arises which is transformed into rent. It should be remembered that the law of differential rent as such is entirely independent of the correctness or incorrectness of this assumption.

Let us call the general price of production, by which the market is regulated, P . Then P coincides for the product of the worst soil A with its individual price of production; that is to say, its price pays for the constant and variable capital consumed in its production plus the average profit (profits of enterprise plus interest).

The rent amounts to zero in this case. The individual price of production of the next better soil B is equal to P' , and P is larger than P' ; that is P pays more than the actual price of production of the product of the soil B . Now let us assume that P minus P' is d ; in this case d , the excess of P over P' , is a surplus profit, which the tenant realises upon class B of soil. This d is converted into rent, which must be paid to the landlord. Let the actual price of production of the third class of soil, C , be P'' , and P minus P'' equal to $2d$; then this $2d$ is converted into rent; likewise let the individual price of production of the fourth class of soil, D , be P''' , and P minus P''' equal to $3d$, which is converted into ground-rent, etc. Now take it that the assumption of a rent upon soil A equal to zero and of a price of production equal to P plus zero is wrong. Rather let the class A of soil also pay a rent, equal to r . In that case we come to two conclusions.

First: The price of the product of the land of class A would not be regulated by its price of production, but by containing a surplus above it would come to $P+r$. For assuming the capitalist mode of production to be in a normal condition, that is, assuming that the surplus r , which the tenant pays to the landlord, is neither a deduction from wages nor from the average

profit of capital, it can be paid only by selling the product above its price of production, so that a surplus profit arises, which the tenant might keep if he did not have to turn it over to the landlord as a rent. In that case the regulating market price of the total product of all soils existing on the market would not be the price of production, which capital generally makes in all spheres of production, which is a price equal to the cost of production plus the average profit, but it would be the price of production plus the rent, $P+r$, and not merely P . For the price of the product of soil A expresses generally the limit of the regulating general market price, at which the total product can be supplied, and to the extent it regulates the price of this total product.

Secondly: Nevertheless the law of differential rent would not be suspended in this case, although the general price of the products of the soil would be essentially modified. For if the price of the product of class A should be $P + r$, and this should be the general market price, then the price of class B would be likewise $P + r$, and so would be the price of classes C, D, etc. But since $P - P' = d$, in the case of class B, it is evident that $(P + r) - (P' + r)$ is also equal to d , and $P - P''$ in the case of class C would mean that $(P + r) - (P'' + r)$ is equal to $2d$, and $P - P'''$ in the case of class D would mean that the formula $(P + r) - (P''' + r)$ is equal to $3d$, and so forth. In other words, the differential rent would still be regulated by the same law as before, although the rent would contain an element independent of this law and would show a general increase in the same way as would the price of the products of the soil. It follows, then, that no matter what may be the condition of the rent upon the least fertile lands, the law of differential rent is not only independent of it, but that also the only manner of viewing differential rent in keeping with its character, is to place the rent of class A at zero. Whether this is zero or larger than zero, is immaterial, so far as the differential rent is concerned, and is not considered in the calculation.

The law of differential rent, then, is independent of the results of the following investigations.

If we now go more deeply into the question, as to what is the sound basis of the assumption that the product of the worst soil A does not pay any rent, we necessarily get the answer: If the market price of the products of the

land, say of grain, reaches such a level that an additional investment of capital in the class A of soils pays the ordinary price of production and yields the ordinary average profit to the capitalist, then this is sufficient incentive for investing additional capital in soil of class A. In other words, this condition satisfies the capitalist that new capital may be invested at the average profit and employed in the normal manner.

It should be noted here that in case, likewise, the market price must be higher than the price of production of A. For as soon as the additional supply has been created, the relation between supply and demand has been altered. Formerly the supply was insufficient, now it is sufficient. So the price must fall. In order to fall, it must have been higher than the price of production of A. But the lesser fertility of the newly added soils of class A brings it about that the price does not fall quite as low as it was at the time when the price of production of the class B regulated the market. The price of production of A forms the limit, not for the temporary, but for the relatively permanent rise of market price.

On the other hand, if the newly cultivated soil is more fertile than that of the hitherto regulating class A, yet only to the extent of satisfying the increased demand, then the market price remains unchanged. The inquiry as to whether the lowest class of land pays any rent, nevertheless coincides also in this case with our present inquiry, for here again the assumption that class A does not pay any rent must be explained out of the fact that the market price satisfies the capitalist tenant that this price will cover the invested capital plus the average profit, in brief, that the market price will cover the price of production of his commodities.

At any rate, the capitalist tenant can cultivate soil of class A under these conditions, in so far as he has any decision in this matter in his capacity as a capitalist. The prerequisite for a normal self-expansion of capital is now present upon soil A. But the fact that the average conditions of self-expansion would now enable the capitalist tenant to invest capital in soil of the class A if he did not have to pay any rent, does not imply that such land is at the disposal of the capitalist without any further ceremony. The circumstance that the capitalist tenant might invest his capital at the average profit, if he did not have to pay any rent, is no incentive for the landlord to

lend his land to the tenant gratis and be so philanthropic as to grant free credit to this friend in business. To assume that this would be done would be to do away with private property in land, for its existence is precisely an obstacle to the investment of capital and to the liberal self-expansion of capital through land. This obstacle does not fall by any means before the simple reflection of the tenant that the condition of grain prices would enable him to get the average profit out of an investment of capital in class A of soil, if he did not have to pay any rent, in other words, if he could proceed as though private property in land did not exist. But differential rent is based upon the fact that private property in land exists, that the land monopoly is an obstacle of capital, for without it the surplus profit would not be converted into ground-rent and would not fall into the hands of the landlord instead of those of the capitalist tenant. Private property in land remains as an obstacle, even where differential rent as such is not paid, that is, upon soils of the class A. If we observe the cases, in which capital may be invested in the land, in a country with capitalist production, without paying any rent, we shall find that they imply, all of them, a practical abolition of private property in land, even if not a legal abolition, a condition which is found only under very definite circumstances, which are in their very nature accidental.

First: This may take place when the landlord is himself a capitalist, or the capitalist himself a landlord. In this case he may himself exploit his land, as soon as the market price shall have risen sufficiently to enable him to get the price of production, that is, cost of production plus the average profit, out of what is now land of class A. But why? Because for himself private property in land is not an obstacle to the investment of his capital. He can treat his land simply as an element of nature, and can listen wholly to considerations of expediency concerning his capital, to capitalist considerations. Such cases occur in practice, but only as exceptions. Just as the capitalist cultivation of the land presupposes the separation of the active capital from property in land, so it excludes as a rule the self-management of property in land. It is evident, that the opposite is only an exception. If the increased demand after grain requires the cultivation of a larger area of land of the class A than is in the hands of self-managing proprietors, in other words, if a part of such land must be rented in order to be cultivated at all, then this hypothetical conception of the obstacle created by private

property in land for capital and its investment at once collapses. It is an absurd contradiction to start out from the differentiation between capital and land, capitalist tenants and landlords, which corresponds to the capitalist system, and then to turn around and assume that the landlords, as a rule, exploit their own land in all cases and to the full extent, where capital would not get a rent out of the cultivation of the soil, if private property in land were not separate and distinct from it. (See the passage from Adam Smith concerning mining rent, quoted further along.) Such an abolition of private property in land is accidental. It may or may not occur.

Secondly: In the total area of some rented land there may be certain portions, which do not pay any rent under the existing condition of market prices, so that they are virtually loaned gratis, although the landlord does not look upon it in that light, because he does not consider the special rent of some particular patches in the total rental of his rented land. In such a case, so far as such patches are exempt from rent, private property as an obstacle to the investment of capital is obliterated for the capitalist tenant, and his contract with the landlord implies as much. But he does not pay any rent for such patches for the simple reason that he pays rent for the land to which they belong. The assumption in this case deals with a combination, in which the worse land of the class A is not an independent resort by which to supply the missing product, but rather an inseparable part of some better land. But the case to be investigated is precisely that in which certain pieces of land of class A are independently cultivated, and must be rented separately under the general conditions of capitalist production.

Thirdly: A capitalist tenant may invest additional capital upon the same rented land, although the additional product secured in this way nets him only the price of production at the prevailing market prices, so that he gets only the average profit, but does not get any surplus profit with which to pay rent. In that case he pays ground-rent with a portion of the capital invested in the land, but does not pay any ground-rent with the remainder of his invested capital. How little this assumption solves the problem in question, is seen by the following considerations: If the market price (and the fertility of the soil) enables him to obtain a larger yield with his additional capital, so that this additional capital secures for him not merely the price of production, the same as his old capital, but also a surplus profit,

then he pockets this surplus profit himself so long as his present lease runs. But why? Because the obstacle of private property has been eliminated for his capital during the time of his lease. But the simple fact, that new and inferior soil must be independently cleared and independently rented, in order to secure this surplus profit for him, proves that the investment of additional capital upon the old soil no longer suffices to fill the required increased demand. One assumption excludes the other. It is true that one might say: The rent of the worst soil A is itself a differential rent compared either to the land cultivated by the owner himself (which is an accidental exception), or with the additional investment of capital upon the old leaseholds which do not produce any rent. However, this would be a differential rent, which would not arise from the difference in fertility of the various classes of soil, and which would, therefore, not be based upon the assumption that class A of soil does not pay any rent and sells its product at the price of production. And furthermore, the question as to whether additional investments of capital upon the same leasehold produce any rent or not is quite immaterial for the question, whether the new soil of class A, which is about to be taken under cultivation, pays any rent or not, just as it is immaterial for the organization of a new and independent manufacturing business whether another manufacturer of the same line of business invests a portion of his capital in interest-bearing papers, because he cannot use all of it in his business; or whether he makes certain improvements, which do not secure the full profit for him, but at least more than interest. This is immaterial for him. The new establishments must produce the average profit and are built on this assumption. It is true that the additional investments upon the old leaseholds and the additional cultivation of new land of class A mutually restrict one another. The limit, up to which additional capital may be invested upon the same leasehold under less favorable conditions of production, is determined by the new competing investments upon soil of class A; on the other hand, the rent which may be produced by this class of soil is limited by the competing additional investments of capital upon the old leaseholds.

But all these false subterfuges do not solve the problem, which in simple language consists of this: Assuming the market price of grain (which shall be typical of all products of the soil in this inquiry) to be sufficient for the purpose of taking portions of soil of class A under cultivation and securing

the price of production (cost of production plus average profit) by means of the capital invested in these new fields, in other words, assuming the conditions for the normal self-expansion of capital upon the soil A to be existent, is this sufficient cause for making the investment of such capital really possible? Or must the market price raise to a point where even the worst soil A will produce a rent? Does the monopoly of the land owner place an obstacle in the way of the capitalist who wants to invest, an obstacle which would not exist from the capitalist's point of view without that monopoly in land? The conditions, under which this question is put, show that the question as to whether capital may really be invested in soil of A class A, which would produce the average profit, but no rent is not at all solved by the fact that, for instance, additional investments upon the old leaseholds may exist, which produce only the average profit but no rent at the prevailing market prices. The question still remains unanswered. The fact that the additional investments, which do not produce any rent, do not satisfy the demand is proved by the necessity of taking new land under cultivation out of class A. If the additional cultivation of land of class A takes place only to the extent that it produces a rent, that is, more than the price of production, then only two cases are possible. Either the market price must be such that even the last additional investment of capital upon the old leaseholds produce a surplus profit, which may be pocketed by the tenant or by the landlord. This raise in price and this surplus profit of the last additional investment of capital would then be a result of the fact that soil A cannot be cultivated without producing a rent. For if the price of production were sufficient to bring about a cultivation of land A, if the mere average profit were enough for that, then the price would not have risen to this point and the competition of new lands would have manifested itself as soon as they could produce just this price of production. The additional investments upon the old leaseholds, which do not produce any rent, would then have to compete with the investments upon soil A, which likewise do not produce any rent. Or, the last investments upon the old leaseholds may not produce any rent, but still the market price may have risen sufficiently to make the cultivation of soil A possible and to get a rent out of it. In this case, the additional investment of capital, which does not produce any rent, would be possible only for the reason that soil A could not be cultivated until the market price enabled it to produce a rent. Without this condition its cultivation would have begun when prices stood lower; and those later

investments of capital upon the old leaseholds, which require a high market price in order to produce the ordinary profit without any rent, could not have taken place. For they produced only the average profit at the high market prices. At a lower market price, which would have become the regulating market price of production from the time that soil A would have been taken under cultivation, those later investments upon the old leaseholds could not have produced this average profit, and this means that the investments would not have been made under such conditions. In this way, the rent of soil A would indeed form a differential rent, compared to the investments upon the old leasehold, which do not produce any rent. But the fact that the area of A forms such a differential rent is but a consequence of the condition that this area is not taken under cultivation at all, unless it produces a rent. The first condition in this case is that the necessity of this rent, which is not based upon any differences of soil, must exist and from a barrier to the possible investment of additional capitals upon the old leaseholds. In either case, the rent of soil A would not be a simple consequence of the rise in grain prices, but on the contrary, the fact that the worst soil must produce a rent in order to become available for cultivation would be the cause of a rise in the price of grain to the point at which this condition may be fulfilled.

The differential rent has this peculiarity, that the landlord merely catches the surplus profit which would otherwise go into the pocket of the tenant, and which the tenant may actually pocket under certain circumstances during the time of his lease. The property in land is here merely the cause of the transfer of a portion of the price of the product, which arises without any active participation of the landlord in production and resolves itself into surplus profit. This transfer of a portion of the price from one individual to another, from the capitalist to the landlord, is due to private property in land. But private ownership of land is not the cause which creates this portion of the price, or brings about the rise in the price, upon which it is conditioned. On the other hand, if the worst soil A cannot be cultivated — although its cultivation would yield the price of production — until it produces something in excess of the price of production, then private property in land is the creative cause of this rise in price. Private property in land itself has created rent. This fact is not altered, if, as in the second case mentioned, the rent now produced by soil A is a differential rent compared

with the last additional investment of capital upon the old leaseholds, which pays only the price of production. For the circumstance, that soil A cannot be cultivated, until the regulating price of production has risen high enough to admit of a rent for soil A, is in this case the sole reason of the rise of the market price to that level, which enables the last investments upon the old leaseholds to secure the price of production, by means of which a rent is obtained from soil A. The fact that this soil has to pay any rent at all is in this case the cause which creates a differential rent between soil A and the last investment upon the old leaseholds.

Speaking in general of the fact that class A of soil, under the assumption that the price of grain is regulated by the price of production, does not pay any rent, we mean rent in the categorical sense of the word. If the tenant pays a rent, which is either a deduction from the normal wages of his laborers, or from his own normal average profit, then he does not pay a rent which is clearly distinguished from wages and profit in the price of his product. We have already indicated that this takes place continually in practice. To the extent that the wages of the agricultural laborers in a certain country are continually depressed below the normal level of wages, so that a part of the wages, being deducted from them, passes generally over into the rent, this is no exception for the tenant upon the worst kind of soil. In the same price of production, which makes the cultivation of the worst soil possible, these low wages already form a constituent element, and the sale of his product at the price of production does not enable the tenant upon this soil to pay any rent. The landlord might rent his land also to some laborer, who may be satisfied to pay all or a part of that in the form of rent which he may get in the selling price above the wages. In all these cases, however, no real rent is paid, but merely lease money. But wherever conditions correspond to the capitalist mode of production, rent and lease money must coincide. It is precisely this normal condition which must be analyzed here.

A reference to colonial conditions proves even less for our problem than do the above-mentioned cases, in which actual investments of capital under conditions of capitalist production may take place upon the land without producing any rent. What makes a colony of a colony — we have in mind only true agricultural colonies — is not merely the vast area of fertile lands in a natural state. It is rather the circumstance that these lands are not

appropriated, are not brought under private ownership. It is this which makes the enormous difference between the old countries and the colonies, so far as the land is concerned, it is this nonexistence, legal or actual, of private property in land, as Wakefield remarks correctly;¹²⁹ and long before him the elder Maribeu, the physiocrat, and other older economists had discovered. It is quite immaterial here, whether the colonists take possession of the land without further ceremony, or whether they pay to the state a fee for a valid title to the land under the title of a nominal price of land. It is also immaterial, that already settled colonists may be legally the owners of land. In fact the land ownership is not an obstacle to the investment of capital here, nor to the employment of labor upon land without any capital. The setting of a part of the land by the established colonists does not prevent the newcomers from employing their capital or their labor upon new land. Therefore, if we are asked to investigate the influence of private ownership of land upon the prices of the products of land and upon the rent in places where such ownership is an obstacle to the investment of capital, it is very absurd to speak of free bourgeois colonies, in which neither the capitalist mode of production in agriculture, nor the form of private property belonging to it, exist, and in which the latter does not exist at all in fact. Ricardo is an illustration of this in his chapter on ground-rent. In the beginning he says that he is going to investigate the effect of the appropriation of land upon the value of the products of the soil, and immediately after that he takes for an illustration the colonies, assuming that real estate exists in a relatively elementary form and that its exploitation is not limited by the monopoly of private ownership in land.

The mere legal property in land does not create any ground-rent for the landlord. But it gives him the power to withdraw his land from exploitation until the economic conditions permit him to utilize it in such a way that it will yield him a surplus, whenever the land is used either for agriculture proper or for other productive purposes, such as buildings, etc. He cannot increase or decrease the absolute quantity of its field of employment, but he can do so with its marketable quantity. For this reason, as Fourier has already remarked, a characteristic fact in all civilized countries is that a comparatively considerable portion of the land always remains uncultivated.

Assuming, then, that the demand requires the opening up of new lands, and that these lands are less fertile than those hitherto cultivated, will the landlord rent such lands for nothing, just because the market price of the products of the soil has risen high enough to pay to the tenant the price of production on his investment in this land and enable him to reap the average profit? By no means. The investment of capital must net him a rent. He does not rent his land until he can get lease money for it. Therefore the market price must have risen above price of production to the point $P+r$, so that a rent can be paid to the landlord. Since the real estate does not net any income, according to our assumption, until it is rented, so that it is economically valueless until then, a small rise of the market price above the price of production will suffice to bring the new land of the worst class upon the market.

The question is now: Does it follow from the ground-rent of the worst soil, which cannot be derived from any difference of fertility, that the price of the products of the soil is necessarily a monopoly price in the ordinary meaning of the term, or a price, into which the rent enters like a tax, only with the distinction that the landlord levies the tax instead of the state? It is a matter of course that this tax has certain definite economic limits. It is limited by the additional investments of capital upon the old leaseholds, by the competition of the products of the soil of foreign countries, which are imported free of duty, by the competition of the landlords among themselves, and finally by the wants and the solvency of the consumers. But this is not the point. The point is whether the rent paid by the worst soil passes into the price of its products, which price regulates the general market price according to our assumption, and whether it enters into this price in the same way as a tax enters into the price of commodities which are dutiable, in other words, whether this rent enters into the price as an element independent of its value.

This does not necessarily follow by any means, and the contention that it does has been made only because the distinction between the value of commodities and their price of production had not been understood up to the present. We have seen that the price of production of a commodity is by no means identical with its value, although the prices of production of all commodities, considered as a whole, are regulated only by their total value,

and although the movement of the prices of production of the various kinds of commodities, taking all other circumstances as equal, is controlled exclusively by the movement of their values. It has been demonstrated that the price of production of a commodity may stand above or below its value, and coincides but rarely with its value. Hence the fact that the products of the soil are sold above their prices of production does not prove by any means that they are sold above their values. Neither does the fact, that the products of industry are, on an average sold at their prices of production, prove that they are sold at their values. It is possible that the products of agriculture are sold above their price of production and below their value, while many products of industry bring the price of production only because they are sold above their value.

The relation of the price of production of a certain commodity to its value is exclusively determined by the proportion, in which the variable part of their capital with which it is produced stands to its constant part, or by the organic composition of the capital producing it. If the composition of the capital in a certain sphere of production is lower than that of the social average capital, in other words, if its variable portion, which is used for wages, is relatively larger than its constant portion, which is invested in material requirements of production, compared to the social average capital, then the value of its products must stand above their price of production. In other words, such a capital, employing more living labor, produces at the same rate of exploitation of labor more surplus-value, and therefore more profit, than an equally larger aliquot portion of the social average capital. The value of its products stands, therefore, above their price of production, since this price of production is equal to the cost of production plus the average profit, and the average profit is lower than the profit produced in these commodities. The surplus-value produced by the social average capital is smaller than that produced by a capital of this lower composition. On the other hand, when the capital invested in a certain sphere of production is of higher than average composition, then the case is reversed. The value of the commodities produced by it stands below their price of production, and this is generally the case with the products of the most highly developed industries.

If the capital in a certain sphere of production is of a lower composition than the social average capital, then this is primarily an expression of the fact that the productive power of the social labor in this particular sphere of production is below the average; for the prevailing degree of productive power shows itself in the relative preponderance of the constant over the variable capital, or in the continual decrease of the portion used in a certain capital for wages. On the other hand, if the capital in a certain sphere of production is of a higher composition, then it expresses a development of the productive power above the average.

Leaving aside the work of artists, which is naturally excluded from our discussion, it is a matter of course that different spheres of production require different proportions of constant and variable capital according to their technical peculiarities, and that living labor must occupy more room in some, less room in others. For instance, in the extractive industries, which must be clearly distinguished from agriculture, raw material as an element of constant capital is wholly absent, and even the auxiliary material plays only rarely an important role in them. Nevertheless the progress of development may be measured also in them by the relative increase of the constant over the variable capital.

If the composition of the capital in agriculture proper is lower than that of the social average capital, then this would be on its face an expression of the fact that in countries with a developed production agriculture has not progressed as far as the industries which work up its products. This fact could be explained, aside from all other economic circumstances which are of paramount importance, from the earlier and more rapid development of mechanical sciences, and especially by their application, compared to the later and partly quite recent development of chemistry, geology and physiology, and particularly their application to agriculture. For the rest it is an indubitable and long known fact¹³⁰ that also the progress of agriculture expresses itself steadily in a relative increase of the constant over the variable capital. Whether in a certain country with capitalist production, for instance in England, the composition of the agricultural capital is lower than that of the social average capital, is a question which can be decided only by statistics, and which need not be discussed in detail for the purposes of this inquiry. So much is theoretically accepted that the value of the

agricultural products cannot be higher than their price of production unless this condition obtains. In other words, a capital of a certain size in agriculture produces more surplus-value, or what amounts to the same, sets in motion and commands more surplus-labor (and with it employs more living labor) than a capital of the same size in industry of social average composition.

This assumption, then, suffices for that form of rent which we are analyzing here, and which can take place only so long as this assumption holds good. Wherever this assumption falls, the form of rent corresponding to it falls likewise.

However, the mere fact of an excess of the value of agricultural products over their price of production would not suffice in itself for the explanation of the existence of a ground-rent, which is independent of differences of fertility or of successive investments of capital upon the same land, a rent which is to be clearly differentiated from differential rent, and which we may therefore call absolute rent. Quite a number of manufactured products have the peculiarity that their value is higher than their price of production, and yet they do not produce any excess above the average profit, a surplus profit, which might be converted into rent. On the other hand, the existence and meaning of the price of production and of the average rate of profit which it implies rest upon the fact that the individual commodities are not sold at their value. The prices of production arise from an equalization of the values of commodities. This equalization after restoring their respective capital values to the various spheres of production, in which they were consumed, distributes the entire surplus-value, not in proportion as it has been produced in the individual spheres of production and incorporated in their commodities, but in proportion to the magnitude of the capital invested in them. Only in this way is an average profit brought about and with it the price of production, whose characteristic element this average profit is. It is the continual tendency of the capitals to bring about this equalization in the distribution of the surplus-value produced by the total capital by means of competition, and to overcome all obstacles to this equalization. This implies the tendency to permit only such surplus profits as arise under all circumstances, not from differences between the values and the prices of production of the commodities, but rather from the general prices of

production, which regulates the market and from the individual prices of production, which differ from it. In other words, only such surplus profits are tolerated, which occur within a certain sphere of production and not such as occur between two different spheres of production, so that they do not touch the general prices of production of the different spheres, or their general rate of profit, but which rather have for their basis the conversion of values into prices of production and into an average rate of profit for the whole. This condition rests, however, as previously explained, upon the continually changing proportional distribution of the total social capital among the various spheres of production, upon the unremitting emigration and immigration of capitals, upon their transfer from one sphere to another, in short upon their free movement between the various spheres of production, which represent so many available fields of investment for the independent constituents of the total capital of society. And the other assumption in this case is that no barrier, or at least only a temporary and accidental barrier, interferes with the competition of the capitals, for instance in some sphere of production, in which the value of the commodities is higher than their prices of production, or where the produced surplus-value is larger than the average profit, so that nothing prevents the reduction of value to a price of production and the proportional distribution of the excess of surplus-value of this sphere of production among all spheres exploited by capital. But if the reverse happens, if capital meets some foreign power, which it cannot overcome, or which it can but partially overcome, and which limits its investment in certain spheres, admitting it only under conditions which wholly or partly exclude that general equalization of surplus-value to an average profit, then it is evident that the excess of the value of commodities in such spheres of production over their prices of production would give rise to a surplus profit, which could be converted into rent and made independent as such compared to profit. Such a foreign power is private ownership of land, when it builds obstacles against capital in its endeavor to invest in land, such a power is the landlord in his relation to the capitalist.

Private property in land is then the barrier which does not permit any new investment of capital upon hitherto uncultivated or unrented land without levying a tax, in other words, without demanding a rent, although the land to be taken under new cultivation may belong to a class which does

not produce any differential rent, and which, were it not for the intervention of private property in land, might have been cultivated at a small increase in the market price, so that the regulating market price would have netted to the cultivator of this worst soil nothing but his price of production. But on account of the barrier raised by private property in land, the market price must rise to a point, where the land can pay a surplus over the price of production, in other words, where it can pay a rent. Now, since the value of the commodities produced by agricultural capital is higher than their price of production, as we have assumed, this rent (with the exception of one case which we shall discuss immediately) forms the excess of the value over the price of production, or a part of it. Whether the rent consumes the entire difference between the value and the price of production, or only a greater or smaller part of it, will depend wholly upon the relation between supply and demand and upon the area of the new land taken in cultivation. So long as the rent is not equal to the excess of the value of agricultural products over their price of production, a portion of this excess would always enter into the general equalization and proportional distribution of all surplus-value among the various individual capitals. As soon as the rent is equal to the excess of the value over the price of production, this entire portion of the surplus-value over and above the average profit would be withdrawn from the equalization. But whether this absolute rent is equal to the whole surplus of value over the price of production, or only equal to a part of it, the agricultural products would always be sold at a monopoly price, not because their price would exceed their value, but because their price would be equal to their value, or because their price would be lower than their value but higher than their price of production. Their monopoly would consist in the fact that they are not, like other products of industry whose value is higher than the general price of production, leveled to the plane of the price of production. Since one portion of the value and of the price of production is an actually existing constant element, namely the cost price, representing the capital k consumed in production, their difference consists in the other, the variable, portion, the surplus-value, which amounts to p in the price of production, that is, to the profit which is equal to the total surplus-value calculated on the social capital and on every individual capital as an aliquot part of the social capital. This profit equals in the value of commodities the actual surplus-value created by this particular capital, and forms an integral part of the value of commodities created by this capital. If

the value of commodities is higher than their price of production, then the price of production is $k+p$, the value $k+p+d$, so that $p+d$ represents the surplus-value contained in it. The difference between the value and the price of production is, therefore, equal to d , the excess of the surplus-value created by this capital over the surplus-value assigned to it by the average rate of profit. It follows from this that the price of agricultural products may stand higher than their price of production, without reaching up to their value. It follows, furthermore, that up to a certain point a permanent increase in the price of agricultural products may take place, before their price reaches their value. It follows also that the excess in the value of agricultural products over their price of production can become a determining element of their general market price only because there is a monopoly in private ownership of land. It follows, finally, that in this case the increase in the price of the product is not the cause of the rent, but rather the rent is the cause of the increase in the price of the product. If the price of the product of the unit of the worst soil is equal to $P+r$, then all differential rents will rise by the corresponding multiples of r , since the assumption is that $P+r$ becomes the regulating market price.

If the average composition of the non-agricultural capital were $85c+15v$, and the rate of surplus-value 100%, then the price of production would be 115. If the composition of the agricultural capital were $75c+25v$, and the rate of surplus-value the same, then the value of the agricultural product and the regulating market price would be 125. If the agricultural and the non-agricultural product should be leveled to the same average price (we assume for the sake of brevity that the total capital in both lines of production is equal), then the total surplus-value would be 40, or 20%, upon the 200 of capital. The product of the one as of the other would be sold at 120. In the equalization into the prices of production the average market prices of the non-agricultural capital would stand above, and those of the agricultural capital below their value. If the agricultural products were sold at their full value, they would stand higher by 5, and the industrial products lower by 5, than they do in the equalization. If the market conditions do not permit the sale of the agricultural products at their full value, at the full surplus above the price of production, then the result hangs between the two extremes; the industrial products would be sold a little above their value, and the agricultural products a little above their price of production.

Although the private ownership of land may drive the price of the products of the soil above their price of production, it does not depend upon this ownership, but upon the general condition of the market, to what extent the market price shall exceed the price of production and approach the value, and to what extent the surplus-value created in agriculture over and above the given average profit shall either be converted into rent or enter into the general equalization of the surplus-value to an average profit. At any rate this absolute rent, which arises out of the excess of value over the price of production, is but a portion of the agricultural surplus-value, a conversion of this surplus-value into rent, its appropriation by the landlord; so does the differential rent arise out of the conversion of surplus-profit into rent, its appropriation by the landlord, under an average price of production which acts as a regulator. These two forms of rent are the only normal ones. Outside of them the rent can rest only upon an actual monopoly price, which is determined neither by the price of production nor by the value of commodities, but by the needs and the solvency of the buyers. Its analysis belongs in the theory of competition, where the actual movement of market-prices is considered.

If all the land suitable for agriculture in a certain country were leased — assuming the capitalist mode of production and normal conditions to be general — then there would not be any soil that would not pay any rent; but there might be certain parts of some capitals invested in land that might not produce any rent. For as soon as the land has been rented, private property in land ceases to be an absolute barrier against the investment of the necessary capital. Still it continues to act as a relative barrier even after that, to the extent that the appropriation of the capital incorporated in the soil by the landlord draws very definite lines for the activity of the tenant. Only in this case would all rent be converted into a differential rent, although this would not be a differential rent determined by any differences in the fertility of the soil, but rather by differences between the surplus profits arising from the last investments of capital in a certain soil and the rent paid for the lease of the soil of the worst quality. Private property in land serves as an absolute barrier to the investment of capital only to the extent that it exacts a tribute for the permission of giving access to the land. As soon as this access has been gained, it can no longer set any absolute obstacles in the

way of the size of any investment of capital in a certain soil. The building of houses meets a barrier in the private ownership of the land upon which the houses are to be built by people who do not own this land. But after this land has once been leased for the purpose of building houses on it, it depends upon the tenant whether he wants to build a large or a small house.

If the average composition of the agricultural capital were the same, or higher than that of social average capital, then absolute rent, in the sense in which we use this term, would disappear; that is, absolute rent which is different from differential rent as well as from the rent which rests upon an actual monopoly price. The value of agricultural capital would not stand above its price of production, in that case, and the agricultural capital would not set any more labor in motion, would not realize any more surplus labor, than the non-agricultural capital. The same would take place, if the composition of the agricultural capital would gradually become the same as that of the average social capital with the progress of civilization.

It looks at first glance like a contradiction, that we should assume that on the one hand the composition of the agricultural capital should become higher, in other words that its constant portion should increase faster than its variable one, and on the other hand that the price of the agricultural product should rise high enough to admit of the payment of a rent on the part of worse soil than that cultivated previously, a rent which in this case could come only from an excess of the market price over the value and the price of production, in short, a rent which could be due only to a monopoly price of the product.

It is necessary to make a clear distinction here.

In the first place, we saw in the discussion of the way, in which the rate of profit is formed, that capitals, which have the same composition, so far as their technological side is concerned, so that they set the same amount of labor in motion compared to machinery and raw materials, may nevertheless have different compositions owing to the different values of the constant portions of capital. The raw materials or the machinery may be dearer in one capital than in the other. In order to set the same quantity of labor in motion (and this would have to be the case, according to our

assumption, in order that the same mass of raw materials might be worked up), a larger capital would have to be advanced in the one case than in the other, since I cannot set the same amount of labor in motion, if the raw material, which must be paid out of 100, costs 40 in one case and 20 in another. But it would become evident that these two capitals have the same technological composition, as soon as the price of the expensive raw material would fall to the level of the cheap. The proportions of value between constant and variable capital would become the same in that case, although no change would have taken place in the technical proportions between the living labor and the mass and nature of the material requirements or production employed by this capital. On the other hand, a capital of low organic composition might assume the appearance of being in the same class with one of a higher organic composition, as soon as the value of its constant parts would rise through changes in the composition of its values. For instance, one capital might be composed of $60\ c + 40\ v$, because it employs much machinery and raw material compared to living labor, and another capital might be composed of $40\ c + 60\ v$, because it employs 60% of living labor, 10% of machinery, and 30% of raw material. In this case a simple rise in the value of raw and auxiliary materials from 30 to 80 would wipe out the difference in composition, for then the second capital would be composed of 10 machinery, 80 raw materials, and 60 labor-power, or of $90\ c + 60\ v$, which, in percentages, would also be equal to $60\ c + 40\ v$, although no change would have taken place in the technical composition. In other words, capitals of the same organic composition may have a different value-composition, and capitals with the same percentages of value-composition may be at different levels of organic composition and thus express different steps in the development of labor's social productivity. The mere circumstance, then, that the agricultural capital might stand upon the general level, would not prove that the social productivity of labor is equally high-developed in it. Nothing would be shown thereby but that its own product, which itself forms one of the conditions of its own production, had become dearer, or that auxiliary materials, such as manure, which used to be close at hand, must now be brought from far distant places, etc.

But aside from this, the peculiar character of agriculture must be taken into consideration.

Even though labor saving machinery, chemical helps, etc., may occupy more space in agriculture, so that the constant capital increases not merely in value, but also in mass, as compared to the mass of the employed labor-power, the question in agriculture (as in mining) is not only one of the social, but also of the natural productivity of labor which depends upon natural conditions. It is possible that the increase of the social productivity in agriculture barely balances or does not even make up for, the decrease in natural power — and compensation through social productivity will always be effective for a short time only — so that in spite of the technical development there is no cheapening of the product, and that at best a greater increase in its price is prevented. It is also possible that the absolute mass of products decreases with a rising price of cereals, while the relative surplus product increases. This could take place, if the constant capital, consisting chiefly of machinery or animals, which require only a reproduction of their wear and tear, would increase relatively, and if the variable capital invested in wages, which must always be reproduced in full out of the product, should decrease correspondingly.

On the other hand it is possible, that only a moderate rise of the market price above the average is necessary, in order to cultivate and draw a rent from soil, which would have required a greater rise of the market prices so long as the technical helps were less developed.

The fact that, say in cattle raising on a large scale, the mass of the employed labor-power is very small compared with the constant capital represented by the cattle, might be considered as a refutation of the claim that the percentage of labor-power set in motion by agricultural capital is larger than that employed by the average social capital outside of agriculture. But it should be noted here that we have taken for our basis in the analysis of rent that portion of the agricultural capital, which produces the principal vegetable food, which is the chief means of subsistence among civilized nations. Adam Smith — and this is one of his merits — has already demonstrated that quite a different method of determining prices is observed in cattle raising, and for that matter generally in the production of agricultural capitals not engaged in raising the principal means of subsistence, say of cereals. For in this case the price of cattle is determined

by the fact that the price of the product of the soil used for cattle raising, say as an artificial pasture, but which might just as well be transformed into cereal fields of a certain quality, must rise high enough to produce the same rent as cereal land of the same quality. In other words, the rent of cereal lands becomes a determining element in the price of cattle. For this reason Ramsay has justly remarked that the price of cattle is artificially raised by the rent, by the economic expression of private ownership of land, in short by the private ownership of land.

Adam Smith says in Book I, Chapter XI, Part I, of his *Wealth of Nations*, that in consequence of the extension of cultivation the uncultivated fallow land no longer suffices to supply the demand for cattle. A large portion of the cultivated lands must be used for breeding and fattening cattle, the price of which must be high enough to pay not merely for the labor spent upon them, but also for the rent which the landlord and the profit which the tenant might have drawn out of this land, had it been cultivated as a field. The cattle raised upon the least tilled peat bogs are sold according to their weight and quality in the same market and at the same price as those raised upon the best cultivated land. The owners of peat bogs profit thereby and raise the rent of their lands in proportion to the prices of cattle.

In this case, likewise, Smith represents the differential rent in favor of the worst soil as distinguished from grain rent.

The absolute rent explains some phenomena, which seem to make a mere monopoly price responsible for the rent, at first sight. Take, for instance, the owner of some forest, which exists without any human assistance, say in Norway. This will do to make a connection with Adam Smith's example. If this owner of the forest receives a rent from some capitalist, who has timber cut, perhaps on account of some demand from England, or if this owner has the timber cut in his own capacity as a capitalist, then a greater or smaller rent will accrue to him in the timber, aside from the profit on the invested capital. This looks like a pure increment from monopoly in the case of this product of nature. But as a matter of fact the capital consists here almost exclusively of variable elements invested in labor-power, and therefore it sets more surplus labor in motion than another capital of the same size. The value of the timber

contains a greater surplus of unpaid labor, or of surplus-value, than that of a product of some capital of higher organic composition. For this reason the average profit can be drawn from this timber, and a considerable surplus in the form of rent can fall into the hands of the owner of the forest. On the other hand it may be assumed that, owing to the case with which the felling of timber as a line of production may be extended, the demand must rise very considerably, in order that the price of timber should equal its value, so that the entire surplus of unpaid labor (over and above that portion which falls into the capitalist's hands as an average profit) may accrue to the landlord in the form of rent.

We have assumed that the newly cultivated soil is of a still lesser quality than the worst previously cultivated one. If it is better, it pays a differential rent. But here we are analyzing precisely that case, in which the rent does not appear as a differential rent. There are only two cases possible under these circumstances. Either the newly cultivated soil is inferior to the previously cultivated soil, or it is just as good. If it is inferior, then we have already analyzed the question. Nothing remains for us to analyze but the case in which it is just as good.

We have already stated in our analysis of differential rent, that the progress of cultivation may just as well take equally good, or even better soil under new treatment as worse soil.

First. In differential rent (or any rent, generally speaking, since even in the case of differential rent the question comes up, whether on the one hand the fertility of the soil in general, and on the other hand its location, admit of its cultivation at the regulating market price in such a way as to produce a profit and a rent) two conditions work in different directions, now paralyzing each other, now alternately exerting the determining influence. The rise of the market price — provided that the cost price of cultivation has not fallen, in other words, provided that no technical progress becomes a new impetus to further cultivation — may bring more fertile soil under cultivation, which was formerly excluded from competition by its location. Or it may, in the case of inferior soil, enhance the advantage of location to such an extent, that its lesser fertility is balanced thereby. Or, without any rise in the market price, the location may carry better soils into competition

through the improvement of means of communication, as we have seen on a large scale in the prairie states of North America. The same takes place also in the older civilized countries, continually if not to the same extent as in the colonies, in which, as Wakefield correctly states, the location determines the case. To sum up, then, the contradictory effects of location and fertility, and the variableness of the factor of location, which is continually balanced and passes perpetually through progressive changes tending towards a balance, carry alternately better or worse classes of soil into new competition with the older ones under cultivation.

Second. With the development of natural history and agronomics the fertility of the soil is also changed, by changing the means through which the elements of the soil may be rendered immediately serviceable. In this way light kinds of soil in France and in the eastern counties of England, which were considered inferior at one time, have recently risen to first place. (See Passy.) On the other hand soil, which was considered inferior, not for the reason that its chemical composition was bad, but that it placed certain mechanical and physical obstacles in the way of cultivation, is turned into good land, as soon as the means for overcoming such obstacles have been discovered.

Third. In all old civilized countries old historical and traditional conditions, for instance in the form of government lands, community lands, etc., have accidentally withdrawn large tracts of land from cultivation, and these come back into it very gradually. The succession, in which they are taken under cultivation, depends neither upon their good quality nor upon their location, but upon wholly external circumstances. In following up the history of English communal lands, as they were successively turned into private property through the Enclosure Bills and cultivated, nothing would be more ridiculous than the phantastic assumption, that a modern agricultural chemist like Liebig had indicated the selection of land in this succession, had designated certain fields for cultivation on account of their chemical peculiarities and excluded others. What decided the point in this case was the opportunity which tempted the thieves, it was the more or less plausible pretenses offered by the great landlords to excuse their appropriation of such lands.

Fourth. Aside from the fact that the stage of development reached at any time by the increased population and capital sets a certain barrier to the extension of cultivation, even though it be an elastic barrier, and aside from the effects of accidents, which temporarily influence the market price, such as a series of good or bad seasons, the extension of agriculture over a larger area depends upon the entire condition of the market in capitals and upon the business condition of the whole country. In periods of stringency it will not be enough that uncultivated soil may produce the average profit for the tenant — no matter whether he pays any rent or not — in order that additional capital be invested in agriculture. On the other hand, in periods with a plethora of capital it will flow into agriculture, even without any rise in market prices, so long as only the other normal conditions are present. Better soil than that hitherto cultivated would be excluded from competition for the sole reason that its location would be unfavorable, or that it would present insurmountable obstacles to its employment for the time being, or that it was kept out by accident. For this reason we must occupy ourselves with soils which are just as good as those last cultivated. Now there is always the difference in the cost of clearing for cultivation between the new soil and the last cultivated one. And it depends upon the stand of market prices and of credit whether new land is cleared or not. As soon as this soil actually enters into competition, the market price falls once more to its former level, assuming other conditions to be equal, and the new soil will then produce the same rent as the corresponding soil formerly cultivated as the last. The theory that it does not produce any rent is proved by its champions by assuming what they are precisely called upon to prove, namely that the soil which used to be the last did not pay any rent. One might prove in the same way that the houses which were built last do not produce any rent except the house rent proper, although they are leased. In fact, however, they do produce a rent even before they yield any house rent, for they often stand vacant for a long time. Just as successive investments of capital in a certain piece of land may bring a proportional surplus and thereby the same rent as the first investment, so fields of the same quality as those last cultivated may bring the same yield at the same cost. Otherwise it would be altogether inexplicable, how fields of the same quality could ever be taken successively under cultivation, and not all of them at the same time, or rather not a single one of them in order to avoid their coming into competition at all. The landlord is always ready to draw a rent, in other

words, to receive something for nothing. But capital requires certain conditions before it can comply with this wish of the landlord. The competition of the lands among themselves does not, therefore, depend upon the wish of the landlord that they should, but upon the opportunities offered to capital for competition with other capitals upon the new fields.

To the extent that the agricultural rent proper is purely a monopoly price, such a price can only be small, just as the absolute rent can only be small under normal conditions, whatever may be the surplus of the product's value over its price of production. The nature of absolute rent, therefore, consists in this: Equally large capitals in different spheres of production produce, according to their different average composition, so long as the rate of surplus-value, or the degree of labor exploitation, is the same, different amounts of surplus-value. In industry these different masses of surplus-value are leveled into an average profit and distributed among the individual capitals uniformly and as aliquot parts of the social capital. Private property in land prevents such an equalization among capitals invested in the soil, whenever production requires real estate, either for agriculture or for the extraction of raw materials, and catches a portion of the surplus value which would otherwise assist in the formation of the average rate of profits. The rent, then, forms a portion of the value, or more specifically of the surplus-value, of commodities and instead of falling into the hands of the capitalists, who extract it from their laborers, it is captured by the landlords, who extract it from the capitalists. The assumption is in this case that the agricultural capital sets more labor in motion than an equally large portion of the non-agricultural capital. How far the difference goes, or whether it exists at all, depends upon the relative development of agriculture as compared to industry. In the nature of the case this difference must decrease with the progress of agriculture, unless the proportion, in which the variable capital decreases as compared to the constant, is still greater in the industrial than in the agricultural capital.

This absolute rent plays an even more important role in the extractive industry, properly so-called, where one element of constant capital, the raw material, is wholly missing, and where, with the exception of those lines, in which the capital consisting of machinery and other fixed capital is very considerable, by far the lowest composition of capital exists. Precisely here,

where the rent seems wholly due to a monopoly price, extraordinarily favorable market conditions are necessary in order that commodities may be sold at their value, or that rent may become equal to the entire excess of surplus-value in a commodity over its price of production. This applies, for instance, to rent in fishing waters, stone quarries, naturally grown forests, etc.¹³¹

CHAPTER XLVI. BUILDING LOT RENT. MINING RENT. PRICE OF LAND.

DIFFERENTIAL rent appears every time and follows the same laws as the agricultural differential rent, wherever rent exists at all. Wherever natural forces can be monopolized and thereby guarantee a surplus profit to the industrial capitalist using these forces, whether it be waterfalls, or rich mines, or waters teeming with fish, or a favorably located building lot, there the person who by his or her title to a portion of the globe has been privileged to own these things will capture a part of the surplus profit of the active capital by means of rent. Concerning mining lands, Adam Smith has explained that the basis of their rent, like that of all land not employed in agriculture, is regulated by the agricultural rent (Book I, Chapter, XI, 2 and 3). This form of rent is distinguished, first, by the overwhelming influence exerted by location upon differential rent (an influence which is very considerable in vineyards and in building lots of large cities); secondly, by the palpable passiveness of the owner, whose sole activity consists (especially in mines) in exploiting the progress of social development, toward which he contributes nothing and for which he risks nothing, unlike the industrial capitalist; and finally by the preponderance of the monopoly price in many cases, particularly by the most shameless exploitation of poverty (poverty is for house rent a more lucrative source than the mines of Potosi ever were for Spain¹³² and by the tremendous power wielded by private property in land when united with industrial capital in the same hand and used for the purpose of practically excluding the laborers in their struggle for wages from the earth as a place of domicile.¹³³ . One section of society thus exacts from another a tribute for the permission of inhabiting the earth. Private property in land implies the privilege of the landlord to exploit the body of the globe, the bowels of the earth, the air, and with them the conservation and development of life. Not only the increase of population, and with it the growing demand for shelter, but also the development of fixed capital, which is either incorporated in the soil or takes root in it and is based upon it, such as all industrial buildings, railroads, warehouses, factory buildings, docks, etc., necessarily increase the building rent. A mistake between the house rent, to the extent that it is

an interest and mortgage upon the capital invested in a house, and the rent for the mere land is not possible in this case, even with all the good will of a Carey, particularly when the landlord and the building speculator are different persons, as they are in England. Two elements should be considered here: On the one hand, the exploitation of the earth for the purpose of reproduction or extraction, on the other hand the space required as an element of all production and all human activity. Private property in land demands its tribute in both directions. The demand for building lots raises the value of the land as a building ground and foundation, and the simultaneous demand for elements of the terrestrial globe serving as building material grows with it.¹³⁴

That it is the ground-rent, and not the house, which forms the actual object of building speculation in rapidly growing cities, especially when building is carried on as an industry, as it is in London, we have already shown in Volume II, Chapter XII, pages 266-267, of the present work, where we quoted from the testimony of a large London building speculator, Edward Capps, given before the Select Committee on Bank Acts. The same man said on that occasion, No. 5435: I believe that a man who wants to get on in the world can hardly expect to get along by sticking to a fair trade....He must of necessity build also on speculation, and that on a large scale; for the contractor makes very little profit out of the buildings themselves, he makes his principal profits out of the rise of ground-rents. He takes up, for instance, a piece of land and pays 300 pounds sterling annually for it. If he erects the right class of houses upon it after a careful building plan, he may succeed in making 400 or 500 pounds sterling out of it, and his profit would consist much more of the increased ground-rent of 100 or 150 pounds sterling annually than of the profit from the buildings, which in many cases he does not consider at all.

And it should not be forgotten that after the lapse of the lease, at the end of 99 years, as a rule, the land with all the buildings upon it and with the ground-rent, generally increased to twice or thrice its original amount, reverts from the building speculator or from his legal successor to the original landlord who was the last to rent it.

The mining rent, in its strict meaning, is determined in the same way as the agricultural rent.

There are some mines, the product of which barely suffices to pay for the labor and to reproduce the capital invested in it together with the ordinary profit. They yield some profit to the contractor, but no rent to the landlord. They can be worked to advantage only by the landowner, who in his capacity of a contractor makes the ordinary profit out of his invested capital. Many coal mines in Scotland are operated in this way, and cannot be operated in any other way. The landowner does not permit anybody to work them without the payment of rent, but no one can pay any rent for them. (Adam Smith, Book I, Chapter XI, 2.)

It is necessary to distinguish, whether the rent flows from a monopoly price, because a monopoly price of the product or of the soil exists independently of it, or whether the products are sold at a monopoly price, because a rent exists. When we speak of a monopoly price, we mean in a general way a price which is determined only by the eagerness of the purchasers to buy and by their solvency, independently of the price which is determined by the general price of production and by the value of the products. A vineyard producing wine of very extraordinary quality, a wine which can be produced only in a relatively small quantity, carries a monopoly price. The winegrower would realize a considerable surplus profit from this monopoly price, the excess of which over the value of the product would be wholly determined by the wealth and the fine appetite of the rich wine drinkers. This surplus profit, which flows from a monopoly price, is converted into rent and in this form falls into the hands of the landlord, thanks to his title to this piece of the globe, which is endowed with peculiar properties. Here, then, the monopoly price creates the rent. On the other hand, the rent would create a monopoly price, if grain were sold not merely above its price of production, but also above its value, owing to the barrier erected by the private ownership of the land against the investment of capital upon uncultivated soil without the payment of rent. That it is only the title of a number of persons to the possession of the globe which enables them to appropriate a portion of the surplus labor of society to themselves, and to do so to an increasing extent with the development of production, is concealed by the fact that the capitalized rent, this capitalized tribute,

appears as the price of the land, and that the land may be sold like any other article of commerce. The buyer, therefore, does not feel that his title to the rent is obtained gratis, and without the labor, the risk, and the spirit of enterprise of the capitalist, but rather that he has paid for it with an equivalent. To the buyer, as we have previously remarked, the rent appears merely as interest on the capital, with which he has bought the land and consequently his title to the rent. In the same way, the slave-holder considers a negro, whom he has bought, his property, not because slavery as such entitles him to that negro, but because he has acquired him just as he does any other commodity, by means of sale and purchase, but the title itself is only transferred, not created by sale. The title must exist, before it can be sold, and a series of sales cannot create this title by repetition any more than one single sale can. It was created in the first place by the conditions of production. As soon as these have arrived at a point, where they must shed their skin, the material source of the title, justified economically and historically and arising from the process which creates the material requirements of life, falls to the ground, and with it all transactions based upon it. From the point of view of a higher economic form of society, the private ownership of the globe on the part of some individuals will appear quite as absurd as the private ownership of one man by another. Even a whole society, a nation, or even all societies together, are not the owners of the globe. They are only its possessors, its users, and they have to hand it down to the coming generations in an improved condition, like good fathers of families.

In the following analysis of the price of land we leave out of consideration all fluctuations of competition, all land speculation, and small landed property, in which the land is the principal instrument of the producers and must, therefore, be bought by them at any price.

The price of land may rise, although the rent may not rise with it. This may take place,

by a mere fall of the rate of interest, which may cause the rent to be sold more dearly, so that the capitalized rent, the price of land rises;

because the interest of the capital incorporated in the land rises.

The price of land may rise, because the rent increases.

The rent may increase, because the price of the product of the land rises, in which case the rate of differential rent always rises, whether the rent upon the worst cultivated soil be large, small or nonexistent. But by the rate we mean the ratio of that portion of surplus-value, which is converted into rent, to the invested capital, which produces the product of the soil. This differs from the ratio of the surplus product to the total product, for the total product does not comprise the entire invested capital, namely not the fixed capital, which continues to exist by the side of the product. But it includes the fact that upon the soils carrying a differential rent an increasing portion of the product is converted into an overplus of a surplus product. Upon the worst soil the increase in the price of the product of the soil first creates a rent and consequently a price of land.

But the rent may also increase without a rise in the price of the product of the soil. This price may remain unaltered, or may even decrease.

If the price remains constant, the rent can grow only (aside from monopoly prices) because, on the one hand, the same amount of capital remains invested in the older lands, while new lands of a better quality are cultivated, which, however, suffice only to cover the increased demand, so that the regulating market price remains unchanged. In this case the price of the old lands does not rise, but the price of the newly cultivated lands rises above that of the older lands.

Or, on the other hand, the rent rises because the mass of the capital exploiting the land increases, while the relative productivity and the market price remain the same. Although the rent remains the same in this case, compared to the invested capital, still its mass, for instance, may be doubled, because the capital itself has doubled. Since no fall in the price has occurred, the second investment of capital yields a surplus profit as well as the first, and it likewise is converted into rent after the expiration of the lease. The mass of the rent rises here, because the mass of capital producing a rent increases. The contention that different investments of capital in succession upon the same piece of land can produce a rent only to the extent that their yield is unequal, so that a differential rent arises, amounts to the

contention that when two capitals of 1,000 pounds sterling each are invested upon fields of equal productivity, only one of them can produce a rent, although these fields belong to the better class of soil, which produces a differential rent. (The mass of the rental, the total rent of a certain country, grows therefore with the mass of capital invested, although the price of the individual pieces of land, or the rate of rent, or the mass of rent upon the individual pieces of land, does not necessarily increase; the mass of the rental grows in this case with the extension of cultivation over a wider area. This may even be combined with a fall of the rent upon the individual holdings.) On the other hand, this contention would lead to another, to the effect that the investment of capital upon two different pieces of land side by side follows different laws than the successive investment of capital upon the same piece of land, whereas differential rent is precisely derived from the identity of the law in both cases, that is, from the increased productivity of investments of capital either upon the same field or upon different fields. The only modification which exists here and is overlooked is that successive investments of capital, when invested upon different pieces of land, meet the barrier of private ownership of land, which is not the case with successive investments of capital upon the same piece of land. This accounts for the opposite effects, by which these two forms of investments keep each other in check in practice. Whatever difference appears here is not due to capital. If the composition of the capital remains the same, and with it the rate of surplus-value, then the rate of profit remains unaltered, so that the mass of profits is doubled when the capital is doubled. In like manner the rate of rent remains the same under the conditions assumed by us. If a capital of 1,000 pounds sterling produces a rent of x , then a capital of 2,000 pounds sterling, under the assumed conditions, produces a rent of $2x$. But calculated with reference to the area of land, which has remained unaltered, since the doubled capital works upon the same field, according to our assumption, the level of the rent has risen together with its mass. The same acre, which brought a rent of 2 pounds sterling, now brings 4 pounds sterling.¹³⁵

The relation of a portion of the surplus-value, of money rent — for money is the independent expression of value — to the land is in itself absurd and irrational. For the magnitudes, which are here measured by one another, are incommensurable, a certain use-value, a piece of land of so and

so many square feet on the one hand, and of so much value, especially surplus-value, on the other. This expresses in fact nothing else but that, under the existing conditions, the ownership of so and so many square feet of land enables the landowner to catch a certain quantity of unpaid labor, which capital wallowing in square feet like a hog in potatoes has realized [The manuscript here has in brackets, but crossed out, the name "Liebig."] But on first sight the expression is the same as though some one were to speak of the relation of a five-pound note to the diameter of the earth. However, the reconciliation of the irrational forms, in which certain economic conditions appear and assert themselves in practice, does not concern the active agents of these relations in their every day life. And as they are accustomed to moving about in them, they do not find anything strange about them. A complete contradiction has not the least mystery for them, They are as much at home among the manifestations which, separated from their internal connections and isolated by themselves, seem absurd, as a fish in the water. The same thing that Hegel says with reference to certain mathematical formulæ applies here. The thing which seems irrational to ordinary common sense is rational, and what seems rational to it is irrational.

When considered in connection with the land area itself, a rise in the mass of the rent expresses itself in the same way that a rise in the rate of the rent does, and this accounts for the embarrassment caused to some thinkers when the conditions, which would explain the one case, are absent in the other.

Finally, the price of land may also rise, even when the price of the products of the soil decreases.

In this case, the differential rent and with it the price of land of the better classes may have risen, owing to further differentiations. Or, if this should not be the case, the price of the products of the soil may have fallen through a greater productivity of labor, but in such a way that the increased productivity more than balances this. Let us assume that one quarter cost 60 shillings. Now, if the same acre, with the same capital, should produce two quarters instead of one, and the price of one quarter should fall to 40 shillings, then two quarters would cost 80 shillings, so that the value of the

product of the same capital upon the same acre would have risen by one-third, although the price per quarter would have fallen by one-third. How this is possible without selling the product above its price of production or above its value, has been shown in the analysis of differential rent. As a matter of fact it is possible only in two ways. Either some bad soil is placed outside of competition, but the price of the better soil increases with the increase of differential rent, owing to the fact that the general improvement affects the various kinds of soil differently. Or, the same price of production (and the same value, in case absolute rent should be paid) expresses itself upon the worst soil through a larger mass of products, when the productivity of labor has become greater. The product represents the same value as before, but the price of its aliquot parts has fallen, while their number has increased. This is impossible, when the same capital has been employed; for in this case the same value always expresses itself through any portion of the product. It is possible, on the other hand, when additional capital has been used for gypsum, guano, etc., in short for improvements which extend their effects over several years. The premise is that the price of the individual quarter falls, but not to the same extent that the number of quarters increases.

These different conditions under which rent may rise and with it the price of land in general, or of particular kinds of land, may partly exist side by side and compete, or the one may exclude the other, so that they act alternately. But it follows from the foregoing that it will not do to conclude offhand that a rise in the price of land signifies also a rise of rent, or that a rise of rent, which always carries with it a rise in the price of land, also signifies a rise in the price of the products of the land.¹³⁶

Instead of tracing to their source the natural causes which lead to an exhaustion of the soil, and which, by the way, were unknown to all economists who have written anything on differential rent, owing to the condition of agricultural chemistry in their day, the shallow conception has been advanced, that any amount of capital cannot be invested in a limited space of land. For instance, the “Westminster Review” maintained against Richard Jones, that all England could not be fed by cultivating Soho Square. If this is considered a special disadvantage of agriculture, it is precisely the opposite which is true. It is possible to invest capital successively with good

results, because the soil itself serves as a means of production, which is not the case with a factory, or is true of it only to a limited extent, since there the land serves only as a basis, as a space, as a foundation for operations upon a certain area. It is true that, compared to scattered handicrafts, great industries may concentrate large productive plants in a small space. But even so, a definite space is always required at any stage of development, and the building of high structures has its practical limits. Beyond these limits any expansion of production demands also an extension of the land area. The fixed capital invested in machinery, etc., does not improve through use, but on the contrary, it wears out. New inventions may, indeed permit some improvement in this respect, but with any given development of the productive power the machine will always deteriorate. If the productive power is rapidly developed, the entire old machinery must be replaced by a better one, so that the old is lost. But the soil, if properly treated, improves all the time. The advantage of the soil is that successive investments of capital may bring gains without losing the older ones, and this implies the possibility of differences in the yields of these successive investments of capital.

CHAPTER XLVII. GENESIS OF CAPITALIST GROUND-RENT.

Introductory Remarks.

WE must be clear in our minds about the real difficulty in the analysis of ground-rent from the point of view of modern economics, to the extent that it is a theoretical expression of the capitalist mode of production. Even many of the more modern writers have not grasped this yet, as is shown by every renewed attempt to find a “new” explanation of ground-rent. The novelty consists almost always in a relapse into long outgrown conceptions. The difficulty is not to explain the surplus product and the surplus-value produced by agricultural capital. This question is solved by the general analysis of the surplus-value produced by all productive capital, no matter in what sphere it may be invested. The difficulty consists rather in demonstrating the source of the surplus over and above the general surplus-value paid by capital invested in the soil to the landlord in the form of rent after the general surplus-value has been distributed among the various capitals by means of the average profit, in other words, after the various capitals have shared in the total surplus-value produced by the social capital in all spheres of production in proportion to their relative size. Quite aside from the practical motives, which urged the modern economists as spokesmen of the industrial capitalists against the landlords to investigate this question, motives which we shall indicate more clearly in the chapter on the history of ground-rent, the question was of paramount interest for them as a theory. To admit that the rising of rent for capital invested in agriculture was due to some particular effect of the sphere of investment, to peculiar qualities of the land itself, was equivalent to giving up the conception of value as such, equivalent to abandoning all attempts at a scientific understanding of this field. Merely the simple observation that the rent is paid out of the price of the products of the soil, a thing which takes place even where rent is paid in kind, provided that the tenant is to get his price of production out of the land, showed the absurdity of the attempt to explain the excess of this price over the ordinary price of production, in other words, to explain the relative dearness of the products of agriculture

out of the excess of the natural productivity of agricultural industry over the productivity of the other lines of industry. For the reverse is true. The more productive labor is, the cheaper is every aliquot part of its product, because the mass of use-values is so much greater, in which the same quantity of labor and with it the same value is incorporated.

The entire difficulty in the analysis of rent, therefore, consists in the explanation of the excess of agricultural profit over the average profit. It is not a question of surplus-value as such, but of the peculiar surplus of surplus-value found in this sphere of production, not a question of the “net product,” but of the excess of this net product over the net product of the other lines of industry. The average profit itself is a product, formed under very definite historical conditions of production by the movement of the process of social life, a product which requires very far-reaching interrelations, as we have seen. In order that we may be able to speak at all of a surplus over the average profit, this average profit itself must already exist as a standard and as a regulator of production, such as it is under capitalist production. For this reason there can be no such thing as a rent in the modern sense, a rent consisting of a surplus over the average profit, over and above the proportional share of each individual capital in the total surplus-value produced by the entire social capital, so long as capital does not perform the function of enforcing all surplus-labor and appropriating at first hand all surplus-value, so long as capital has not yet brought under its control the social labor, or has done so only sporadically. It shows the naiveté of a man like Passy (see further along) that he speaks of a rent, a surplus over the profit, in primitive society, a surplus over and above a historically defined form of surplus-value, which, according to Passy, might almost exist without any society.

For the older economists, who make the first beginning in an analysis of the capitalist mode of production, which was still undeveloped in their day, the analysis of rent either offers no difficulty, or a difficulty of another sort. Petty, Cantillon, and in general the writers who are closer to feudal times, assume that ground-rent is the normal form of surplus-value, whereas profit to them is still vaguely combined with wages, or at best looks to them like a portion of surplus-value filched by the capitalist from the landlord. These writers take their departure from a condition, in which the agricultural

population still constitutes the overwhelming majority of the nation, and in which the landlord still appears as the individual, who appropriates at first hand the surplus labor of the direct producers through his land monopoly, in which land therefore still appears as the chief requisite of production. These writers could not yet face the question, which, contrary to them, seeks to investigate from the point of view of capitalist production, how it happens that private ownership in land manages to wrest from capital a portion of the surplus-value produced by it at first hand (that is, filched by it from the direct producers) and first appropriated by it.

The physiocrats are troubled by a difficulty of another kind. Being in fact the first systematic spokesman of capital, they try to analyze the nature of surplus-value in general. This analysis coincides for them with the analysis of rent, the only form of surplus-value that exists for them. Therefore the rent-paying, or agricultural capital, is to them the only capital which produces any surplus-value, and the agricultural labor set in motion by it the only labor which makes for surplus-value, which quite correctly is considered the only productive labor from a capitalist point of view. They are right in considering the production of surplus-value as the essential thing. Aside from other merits set forth by us in the volume dealing with "Theories of Surplus-Value," they have the great merit of going back from the merchants' capital, which performs its functions wholly in the sphere of circulation, to the productive capital. In this they are opposed to the mercantile system, which, with its crude realism, constitutes the dominating vulgar economy of that time pushing the beginnings of scientific analysis by Petty and his successors into the background by means of its practical interests. By the way, in this critique of the mercantile system we aim only at its conceptions of capital and surplus-value. We have already indicated previously that the monetary system correctly proclaims production for the world market and the transformation of the product into commodities, and thus into money, as the prerequisite and condition of capitalist production. In the further development of this system into the mercantile system, it is no longer the transformation of the value of commodities into money, but the production of surplus-value, which decides the point, but merely from the meaningless point of view of the sphere of circulation and with the understanding that this surplus-value must present itself as surplus money in the surplus of the balance of trade. The characteristic mark of the interested

merchants and manufacturers of that time, which is adequate to the period of capitalist development represented by them, is found in the fact that their principal aim in the transformation of the feudal and agricultural societies into industrial ones and in the corresponding industrial struggle of the nations upon the world market is a hastened development of capital, which is not supposed to take place in the so-called natural way, but by means of forced measures. It makes a tremendous difference, whether the national capital is gradually and slowly transformed into industrial capital, or whether the time of this development is hastened by means of a tax which they impose through protective duties mainly upon the real estate owners, the middle class and small farmers, and the handicraftsmen, by the accelerated expropriation of the independent direct producers, by a violently hastened accumulation and concentration of capitals, in short by a hastened introduction of the conditions of capitalist production. It makes at the same time an enormous difference in the capitalist and industrial exploitation of the natural powers of national production. Hence the national character of the mercantile system is not a mere phrase in the mouths of its spokesmen. Under the pretense of occupying themselves merely with the wealth of the nation and the resources of the state, they practically proclaim the interests of the capitalist class and the gathering of riches to be the ultimate end of the state, and so they proclaim bourgeois society against the old supernatural state. But at the same time they are conscious of the fact that the development of the interests of capital and of the capitalist class, of capitalist production, is the foundation of the national power and of the national preponderance in modern society.

The physiocrats are, furthermore, correct in stating that the production of surplus-value, and with it all development of capital, has for its natural basis the productivity of agricultural labor. If human beings are not capable of producing by one day's labor more means of subsistence, which signifies in its strictest sense more products of agriculture, than every laborer needs for his own reproduction, if the daily expenditure of his entire labor-power suffices only to produce the means of subsistence indispensable for his own individual needs, then there can be no mention of any surplus product nor of any surplus-value. A productivity of agricultural labor exceeding the individual requirements of the laborer is the basis of all societies, and is above all the basis of capitalist production, which separates a continually

increasing portion of society from the production of the immediate requirements of life and transforms them into “free heads,” as Steuart has it, making them available for exploitation in other spheres.

But what are we to say of more recent writers on economics, such as Daire, Passy, etc., who repeat the most primitive conceptions concerning the natural requirements of surplus labor and surplus-value in general, at a time when classic economy is in its declining years, or even on its deathbed, and who imagine that they are thus saying something new and convincing on ground-rent, after this ground-rent has long developed a peculiar form and has become a specific part of surplus-value?

It is precisely characteristic of vulgar economy that it repeats things which were new, original, deep and justified during a certain outgrown stage of development, at a time when they have become platitudinous, stale, false. In this way it confesses that it has not the slightest suspicion of the problems which used to occupy the attention of classic economy. It confounds them with questions that could be posed only on a low level in the development of bourgeois society. It is the same with its restless and self-complacent rumination of the physiocratic phrases concerning free trade. These phrases have long lost all theoretical interest, no matter how much they may engage the practical attention of this or that modern state.

In natural economy, properly so-called, when no part of the agricultural product, or but a very insignificant part of it, enters into the process of circulation, or even but a relatively small portion of that part of the product which represents the revenue of the landlord, as it did in many Roman *latifundia*, or upon the *villae* of Charlemagne, or more or less during the entire Middle Ages (see Vincard, *Histoire du Travail*), the product and the surplus product of the large estates consists by no means purely of the products of agricultural labor. Domestic handicrafts and manufacturing labor, as side issues to agriculture, which forms the basis, is the prerequisite of that mode of production upon which natural economy rests, in European antiquity and Middle Ages as well as in the Indian commune of the present day, in which the traditional organization has not yet been destroyed. The capitalist mode of production completely dissolves this connection. This process may be studied on a large scale during the last third of the 18th

century, in England. Brains that had grown up in more or less semi-feudal societies, for instance Herrenschwand, still consider this separation of manufacture from agriculture as a foolhardy social adventure, as an unthinkably risky mode of existence, even as late as the close of the 18th century. And even in the agricultural societies of antiquity, which show the greatest analogy to capitalist agriculture, namely Carthage and Rome, the similiarity with plantation management is greater than with that form which really corresponds to the capitalist mode of exploitation.¹³⁷

There existed at one time a formal analogy, which, however, appears as a deception in all essential points to a man familiar with the capitalist mode of production, and who does not, like Mr. Mommsen,¹³⁸ discover a capitalist mode of production in every monetary economy. This formal analogy did not exist at all in continental Italy during antiquity, but at best only in Sicily, because this island served as an agricultural tributary for Rome, so that its agriculture was chiefly aimed at export. It was there that tenants of the modern kind existed.

An incorrect conception of the nature of rent is based upon the fact that rent in a natural form, either as tithes to the church, or as a curiosity perpetuated by old contracts, has dragged itself into modern times out of the natural economy of feudal days, quite contrary to the conditions of the capitalist mode of production. This creates the impression that rent does not arise from the price of the agricultural product, but from its mass, not from social conditions, but from the soil. We have shown previously that a surplus product, representing a mere increase in the mass of products, does not constitute any surplus-value, although surplus-value represents itself in a surplus product. A surplus product may represent a minus in value. Otherwise the cotton industry of 1860, compared to that of 1840, would represent an enormous surplus-value, whereas on the contrary the price of the yarn has fallen. The rent may increase enormously through a succession of crop failures, because the price of cereals rises, although this surplus-value is represented by an absolutely decreasing mass of dearer wheat. Vice versa, the rent may fall through a succession of fertile years, because the price falls, although the fallen rent is represented by a greater mass of cheaper wheat.

With regard to rent in kind it should be noted that it is a mere tradition dragged over from an outgrown mode of production and eking out an existence as a ruin. Its contradiction to the capitalist mode of production is shown by the fact that it disappeared from private contracts of its own accord, and that it was shaken off by force as an inconsistency in such instances as the church tithes in England, where legislation was able to step in. Furthermore, where rent in kind continued to exist on the basis of capitalist production, it was nothing else, and could be nothing else, but an expression of money rent in medieval garb. For instance, wheat is quoted at 40 shillings per quarter. One portion of this wheat has to reproduce the wages contained in it, and must be sold in order to be available for renewed expenditure. Another portion must be sold in order to pay its share of the taxes. Seeds and even a part of the manure enter as commodities into the process of reproduction, wherever the capitalist mode of production and division of labor are developed, and they must be bought for the purposes of reproduction. Therefore another portion of this quarter must be sold, in order to get money for these things. To the extent that they do not have to be bought as actual commodities, but are taken in their natural form out of the product, in order to enter once more as means of production into its reproduction — which is done, not only in agriculture, but in many other lines of production which create constant capital — they figure in the accounts as money of account and are thus deducted as component parts of the cost-price. The wear and tear of machinery, and of fixed capital in general, must be made good in money. And finally comes the profit, which is calculated on the basis of this sum of costs expressed either in real or in accounting money. This profit is represented by a definite portion of the gross product, which is determined by its price. The portion which then remains is the rent. If the rent in kind stipulated by contract is greater than this remainder determined by the price, then it is not a rent, but a deduction from the profit. On account of this possibility alone rent in kind is an old form, to the extent that it does not follow the price of the product, but may amount to more or less than the real rent, so that it may not only contain a deduction from the profit, but also from elements required for the reproduction of the capital. In fact, this rent in kind, so far as it is a rent, not merely in name but in essence, is exclusively determined by the excess of the price of the product over, its cost of production. Only it assumes this variable magnitude to be a constant one. But it is such a comforting

reflection that the natural product should suffice, in the first place, to maintain the laborer, in the second place, to leave for the capitalist tenant more food than he needs, and finally, that the remainder should form a natural rent. The same fancy is indulged in when a manufacturer of cotton goods produces 200,000 yards of them. These yards are supposed to suffice for the purpose of clothing his laborers, his wife and all his offspring, together with himself abundantly, to leave over some cotton for sale, and besides to pay an enormous rent with cotton goods. The matter is so simple! Deduct the cost of production from 200,000 yards of cotton goods, and a surplus must remain for rent. But it is indeed a naïve conception, to deduct the cost of production of, say, 10,000 pounds sterling from 200,000 yards of cotton, without knowing the selling price, to deduct money from cotton goods, to deduct from a natural use-value an exchange-value, and thus to determine the surplus of yards of cotton goods over pounds of sterling. It is worse than the squaring of the circle, which is at least based upon the conception that there is a boundary at which straight lines and curves flow imperceptibly into each other. But such is the recipe of Mr. Passy. Deduct money from cotton goods, before the cotton goods have been converted into money, either in your head or in reality! What remains is the rent, which, however, is to be grasped tangibly (see for instance, Karl Arnd) and not by deviltries of sophistry. The entire restoration of rent in kind amounts really to this foolishness, to this deduction of the price of production from so and so many bushels of wheat, the subtraction of a sum of money from a cubic measure.

Labor Rent.

If we observe ground-rent in its simplest form, that of labor rent, which means that the direct producer cultivates during a part of the week, with instruments of labor (plow, cattle, etc.), actually or legally belonging to him, the soil owned by him in fact, and works during the remaining days upon the estate of the feudal lord, without any compensation from the feudal lord, the proposition is quite clear, for in this case rent and surplus-value are identical. The rent, not the profit, is here the form through which the unpaid surplus labor expresses itself. To what extent the laborer, the self-sustaining serf, can here secure for himself a surplus above his indispensable necessities of life, a surplus above the thing which we would call wages under the capitalist mode of production, depends, other circumstances

remaining unchanged, upon the proportion, in which his labor time is divided into labor time for himself and forced labor time for his feudal lord. This surplus above the indispensable requirements of life, the germ of that which appears as profit under the capitalist mode of production, is therefore wholly determined by the size of the ground-rent, which in this case not only is unpaid surplus labor, but also appears as such. It is unpaid surplus labor for the “owner” of the means of production, which here coincide with the land, and so far as they differ from it, are mere accessories to it. That the product of the laboring serf must suffice to reproduce both his subsistence and his requirements of production, is a fact which remains the same under all modes of production. For it is not a result of its specific form, but a natural requisite of all continuous and reproductive labor, of any continued production, which is always a reproduction, including the reproduction of its own labor conditions. It is furthermore evident that in all forms, in which the direct laborer remains the “possessor” of the means of production and labor conditions of his own means of subsistence, the property relation must at the same time assert itself as a direct relation between rulers and servants, so that the direct producer is not free. This is a lack of freedom which may be modified from serfdom with forced labor to the point of a mere tributary relation. The direct producer, according to our assumption, is here in possession of his own means of production, of the material labor conditions required for the realization of his labor and the production of his means of subsistence. He carries on his agriculture and the rural house industries connected with it as an independent producer. This independence is not abolished by the fact that these small farmers may form among themselves a more or less natural commune in production, as they do in India, since it is here merely a question of independence from the nominal lord of the soil. Under such conditions the surplus labor for the nominal owner of the land cannot be filched from them by any economic measures, but must be forced from them by other measures, whatever may be the form assumed by them.¹³⁹

This is different from slave or plantation economy, in that the slave works with conditions of labor belonging to another. He does not work as an independent producer. This requires conditions of personal dependence, a lack of personal freedom, no matter to what extent, a bondage to the soil as its accessory, a serfdom in the strict meaning of the word. If the direct

producers are not under the sovereignty of a private landlord, but rather under that of a state which stands over them as their direct landlord and sovereign, then rent and taxes coincide, or rather, there is no tax which differs from this form of ground-rent. Under these circumstances the subject need not be politically or economically under any harder pressure than that common to all subjection to that state. The state is then the supreme landlord. The sovereignty consists here in the ownership of land concentrated on a national scale. But, on the other hand, no private ownership of land exists, although there is both private and common possession and use of land.

The specific economic form, in which unpaid surplus labor is pumped out of the direct producers, determines the relation of rulers and ruled, as it grows immediately out of production itself and reacts upon it as a determining element. Upon this is founded the entire formation of the economic community which grows up out of the conditions of production itself, and this also determines its specific political shape. It is always the direct relation of the owners of the conditions of production to the direct producers, which reveals the innermost secret, the hidden foundation of the entire social construction, and with it of the political form of the relations between sovereignty and dependence, in short, of the corresponding form of the state. The form of this relation between rulers and ruled naturally corresponds always with a definite stage in the development of the methods of labor and of its productive social power. This does not prevent the same economic basis from showing infinite variations and gradations in its appearance, even though its principal conditions are everywhere the same. This is due to innumerable outside circumstances, natural environment, race peculiarities, outside historical influences, and so forth, all of which must be ascertained by careful analysis.

So much is evident in the case of labor rent, the simplest and most primitive form of rent: The rent is here the original form of surplus-value and coincides with it. Furthermore, the identity of surplus-value with unpaid labor of others does not need to be demonstrated by any analysis in this case, because it still exists in its visible, palpable form, for the labor of the direct producer for himself is still separated by space and time from his labor for the landlord, and this last labor appears clearly in the brutal form

of forced labor for another. In the same way the “quality” of the soil to produce a rent is here reduced to a tangibly open secret, for the nature which here furnishes the rent also includes the human labor-power bound to the soil, and the property relation which compels the owner of labor-power to exert this quality and to keep it busy beyond the measure required for the satisfaction of his own material needs. The rent consists directly in the appropriation, by the landlord, of this surplus expenditure of labor-power. For the direct producer pays no other rent. Here, where surplus-value and rent are not only identical, but where surplus-value obviously has the form of surplus labor, the natural conditions, or limits, of rent lie on the surface, because those of surplus-value do. The direct producer must, 1), possess enough labor-power, and 2), the natural conditions of his labor, which means in the first place the soil cultivated by him, must be productive enough, in one word, the natural productivity of his labor must be so great that the possibility of some surplus labor over and above that required for the satisfaction of his own needs shall remain. It is not this possibility which creates the rent. The rent is not created until compulsion makes a reality of this possibility. But the possibility itself is conditioned upon subjective and objective facts of nature. And there is nothing mysterious about it. If the labor-power is small, and the natural conditions of labor poor, then the surplus labor is small, but so are in that case the wants of the producers on one side and the relative numbers of the exploiters of surplus labor on the other, and so is finally the surplus product, by which this little productive surplus labor is represented for those few exploiting land owners.

Finally, labor rent implies in itself that, all other circumstances remaining equal, it will depend wholly upon the relative amount of surplus labor, or forced labor, to what extent the direct producer shall be enabled to improve his own condition, to acquire wealth, to produce a surplus over and above his indispensable means of subsistence, or, if we wish to anticipate the capitalist mode of expression, whether he shall be able to produce a profit for himself, and how much of a profit, meaning a surplus over the wages produced by himself. The rent is here the normal, all absorbing, one might say legitimate, form of surplus labor. So far from being a surplus over the profit, which means in this case in excess of any other surplus over the wages, it is rather the amount of profit, and even its very existence, which

depends, other circumstances being equal, upon the amount of rent, or upon the forced surplus labor to be surrendered to the landlord.

Some historians have expressed astonishment that it should be possible for the forced laborers, or serfs, to acquire any independent property, or relatively speaking, wealth, under such circumstances, since the direct producer is not an owner, but only a possessor, and since all his surplus labor belongs legally to the landlord. However, it is evident that tradition must play a very powerful role in the primitive and undeveloped circumstances, upon which this relation in social production and the corresponding mode of production are based. It is furthermore clear that here as everywhere else it is in the interest of the ruling section of society to sanction the existing order as a law and to perpetuate its habitually and traditionally fixed limits as legal ones. Aside from all other matters, this comes about of itself in proportion as the continuous reproduction of the foundation of the existing order and of the relations corresponding to it gradually assume a regulated and orderly form. And such regulation and order are themselves indispensable elements of any mode of production, provided that it is to assume social firmness and an independence from mere accident and arbitrariness. It is just through them that society is rendered more firm and emancipated relatively from mere arbitrariness and mere accident. Society assumes this form by the repeated reproduction of the same mode of production, where the process of production stagnates and with it the corresponding social relations. If this continues for some time, this order fortifies itself by custom and tradition and is finally sanctioned as an expressed law. Since the form of this surplus labor, of forced labor, rests upon the imperfect development of all productive powers of society, and upon the crudeness of the methods of labor itself, it will naturally absorb a much smaller portion, relatively, of the total labor of the direct producers than under developed modes of production, particularly under the capitalist mode of production. Take it, for instance, that the forced labor for the landlord originally amounted to two days per week. These two days of forced labor are fixed, are a constant magnitude, legally regulated by laws of usage or written laws. But the productivity of the remaining days of the week, over which the direct producer has independent control, is a variable magnitude, which must develop in the course of his experience, together with the new wants he acquires, together with the expansion of the

market for his product, together with the increasing security which guarantees independence for this portion of his labor-power. These things will spur him on to a greater exertion of his labor-power, and it must not be forgotten that the employment of his labor-power is by no means confined to agriculture, but includes rural house industry. The possibility of a certain economic development, depending, of course, upon the favor of circumstances, upon inborn race characteristics, etc., is open in this case.

Rent in Kind.

The transformation of labor rent into rent in kind does not change anything in the nature of rent, economically speaking. This nature, in the forms of rent considered here, is such that rent is the sole prevailing and normal form of surplus labor, or surplus-value. This, again, expresses the fact that rent is the only surplus labor, or the only surplus product which the direct producer, being in possession of the labor conditions needed for his own reproduction, must give up to the owner of the land, which under this state of things is the one condition of labor embracing everything. And furthermore it expresses the fact that land is the only labor condition, which stands opposed to the direct producer as a property independent of him and held in the hands of another, being personified by the landlord. To the extent that rent in kind is the prevailing and dominant form of ground-rent, it is always more or less in the company of survivals of the preceding form, that is of rent paid directly by labor, forced labor, no matter whether the landlord be a private person or the state. Rent in kind requires a higher state of civilization for the direct producer, a higher stage of development of his labor and of society in general. And it is distinguished from the preceding form by the fact that the surplus labor is no longer performed naturally, is no longer performed under the direct supervision and compulsion of the landlord or of his representatives. The direct producer is rather driven by the force of circumstances than by direct coercion, rather by legal enactment than by the whip, to perform surplus labor on his own responsibility. Surplus production, in the sense of a production beyond the indispensable needs of the direct producer, and within the field of production actually in his own possession, upon the soil exploited by himself and no longer upon the lord's estate outside of his own land, has become a matter of fact rule here. In this relation the direct producer is more or less master of the employment of his whole labor time, although a

part of this labor time, at first practically the entire surplus portion of it, belongs to the landlord without any compensation. Only, the landlord does not get this surplus labor any more in its natural form, but rather in the natural form of the product in which it is realized. The burdensome interruption by the labor for the landlord (see Volume I, chapter X, 2, Manufacturer and Boyard), which disturbs the reproduction of the serf more or less, according to the way in which forced labor is regulated, disappears, wherever rent in kind has its pure form, or at least it is reduced to a few short intervals during the year, which demand a continuation of rent by forced labor by the side of rent in kind. The labor of the producer for himself and his labor for the landlord are no longer palpably separated by time and space. This rent in kind, in its pure form, while it may drag itself along sporadically into more highly developed modes of production and conditions of production, nevertheless requires for its existence a natural economy, that is an economy in which the conditions of production are either wholly or for the overwhelming part produced by the system itself in such a way that they are reproduced directly out of its gross product. It furthermore requires the combination of domestic rural industry with agriculture. The surplus product, which forms the rent, is the product of this combined agricultural and industrial family labor, no matter whether rent in kind contains more or less of the industrial product, as it often does in the middle ages, or whether it is paid only in the form of actual products of the soil. In this form of rent it is by no means necessary that rent in kind, which represents the surplus labor, should fully exhaust the entire surplus labor of the rural family. Compared to labor rent, the producer rather has more elbow room to gain time for some surplus labor whose product shall belong to himself, as does that of the labor which produces his indispensable means of subsistence. This form will also give rise to greater differences in the economic situation of the individual direct producers. At least the possibility for such a differentiation exists, and so does the possibility that the direct producer may have acquired the means to exploit other laborers for himself, but this does not concern us here, since we are dealing with rent in its pure form. Neither can we pay any heed to the endless variety of combinations, by which the various forms of rent may be united, adulterated and amalgamated.

Owing to the peculiar form of rent in kind, by which it is bound to a definite kind of products and of production, owing furthermore to the indispensable combination of agriculture and domestic industry attached to it, also to the almost complete selfsufficiency in which the peasant family supports itself and to its independence from markets and from the movement of production and history in the social spheres outside of it, in short owing to the character of natural economy in general this form is quite suitable for becoming the basis of stationary conditions of society, such as we see in Asia. Here, as previously in the form of labor rent, ground-rent is the normal form of surplus-value, and thus of surplus labor, that is of the entire surplus labor performed without any equivalent by the direct producer for the benefit of the owner of his essential means of production, the land, a labor which is still performed under compulsion, although no longer in the old brutal form. The profit, if, falsely anticipating, we may so call that portion of the direct producer's labor which exceeds his necessary labor and which he keeps for himself, has so little to do with determining the rent in kind, that this profit rather grows up behind the back of the rent and finds its natural limit in the size of the rent in kind. This rent may assume dimensions which seriously threaten the reproduction of the conditions of labor, of the means of production. It may render an expansion of production more or less impossible, and grind the direct producers down to the physical minimum of means of subsistence. This is particularly the case, when this form is met and exploited by a conquering industrial nation, as India is by the English.

Money Rent.

By money rent we mean here — for the sake of distinction from the industrial and commercial ground-rent resting upon the capitalist mode of production, which is but a surplus over the average profit — that ground-rent which arises from a mere change of form of rent in kind, just as this rent in kind, in its turn, is but a modification of labor rent. Under money rent, the direct producer no longer turns over the product, but its price, to the landlord (who may be either the state or a private individual). A surplus of products in their natural form is no longer sufficient; it must be converted from its natural form into money. Although the direct producer still continues to produce at least the greater part of his means of subsistence himself, a certain portion of this product must now be converted into

commodities, must be produced as commodities. The character of the entire mode of production is thus more or less changed. It loses its independence, it remains no longer detached from the social connections. The proportion of the cost of production, which now is more and more complicated with the expenditure of money, now becomes a determining factor. At any rate, the excess of that portion of the gross product, which must be converted into money, over that portion, which has to serve either as means of reproduction or as means of direct subsistence, assumes a determining role. However, the basis of this rent remains the same as that of the rent in kind, from which it starts, although money rent likewise approaches its dissolution. The direct producer still is the possessor of the land, either by inheritance or by some other traditional right, and he has to perform for his landlord, who is the owner of the land, of his most essential instrument of production, forced surplus labor, that is, unpaid labor for which no equivalent is returned, and this forced surplus labor is now paid in money obtained by the sale of the surplus product. The property in requirements of labor separate from the land, such as agricultural implements and other movable things, is transformed into the property of the direct producer even under the preceding form of rent, first in fact, then legally, and this is the condition even more under money rent. The transformation of rent in kind into money rent, taking place first sporadically, then on a more or less national scale, requires a considerable development of commerce, of city industries, of the production of commodities in general, and with them of the circulation of money. It furthermore requires that products should have a market price, and that they are sold more or less approximately at their values, which need not necessarily be the case under the preceding forms. In the East of Europe we may still see in a certain measure this transformation with our own eyes. How little it can be carried through without a certain development of the social productivity of labor, is proved by various unsuccessful attempts to carry it through under the Roman emperors, and by relapses into rent in kind after the attempt had been made to convert at least that portion of rent in kind into a money rent which had to be paid as a state tax. The same difficulties of transition are shown, for instance, by the prerevolutionary time in France, when money rent was combined and adulterated by survivals of the forms preceding it.

Money rent, as a converted form of rent in kind and as an antagonist of rent in kind, is the last form, and the dissolving form, of that form of ground-rent, which we have considered so far, namely of ground-rent, which we have considered so far, namely of ground-rent as the normal form of surplus-value and of the unpaid surplus labor to be performed for the owner of the means of production. In its pure form, this rent, like labor rent and rent in kind, does not represent any surplus above the profit. It absorbs the profit, as it is understood. To the extent that profit arises in fact as a separate portion of the surplus labor by the side of the rent, money rent as well as rent in its preceding forms still is the normal barrier of such embryonic profit, which can only develop in proportion as the possibility of exploitation grows, whether it be the producer's own surplus labor or the surplus labor of another, which remains after the surplus represented by money rent has been paid. If any profit actually arises along with this rent, this profit is not a barrier of rent, but the rent is rather a barrier of this profit. However, we repeat that money rent is at the same time the disappearing form of the rent which we have considered so far, of that rent which is identical with surplus-value and surplus labor, of ground-rent as the normal and prevailing form of surplus-value.

In its further development money rent must lead — aside from all intermediate forms, such as that of the small peasant who is a tenant — either to the transformation of land into independent peasants' property, or into the form corresponding to the capitalist mode of production, that is, to rent paid by the capitalist tenant.

With the coming of money rent the traditional and customary relation between the landlord and the subject tillers of the soil, who possess and cultivate a part of the land, is turned into a pure money relation fixed by the rules of positive law. The cultivating possessor thus becomes virtually a mere tenant. This transformation serves on the one hand, provided that other general conditions of production permit such a thing, to expropriate gradually the old peasant possessors and to put in their place capitalist tenants. On the other hand it leads to a release of the old possessors from their tributary relation by buying themselves free from their landlord, so that they become independent farmers and free owners of the land tilled by them. The transformation of rent in kind into money rent is not only

necessarily accompanied, but even anticipated by the formation of a class of propertyless day laborers, who hire themselves out for wages. During the period of their rise, when this new class appears but sporadically, the custom necessarily develops among the better situated tributary farmers of exploiting agricultural laborers for their own account, just as the wealthier serfs in feudal times used to employ serfs for their own benefit. In this way they gradually acquire the ability to accumulate a certain amount of wealth and to transform themselves even into future capitalists. The old selfemploying possessors of the land thus give rise among themselves to a nursery for capitalist tenants, whose development is conditioned upon the general development of capitalist production outside of the rural districts. This class grows very rapidly, when particularly favorable circumstances come to its aid, as they did in England in the 16th century, where the progressive depreciation of money made them rich, under the customary long leases, at the expense of the landlords.

Furthermore: As soon as rent assumes the form of money rent, and with it the relation between rent paying peasants and landlords becomes a relation fixed by contract — a development which is not possible unless the world market, commerce and manufacture have reached a relatively high level — the leasing of land to capitalists necessarily also puts in its appearance. These men, having stood outside of the rural barrier so far, now transfer to the country and to agriculture some capital acquired in the cities and with it the capitalist mode of production as developed in those cities, which implies the creation of the product in the form of a mere commodity and as a mere means of appropriating surplus-value. This form can become the general rule only in those countries, which dominate the world market in the period of transition from the feudal to the capitalist mode of production. When the capitalist tenant steps between the landlord and the actually working tiller of the soil, all conditions have been dissolved, which arose from the old rural mode of production. The capitalist tenant becomes the actual commander of these agricultural laborers and the actual exploiter of their surplus labor, whereas the landlord has any direct relations only with this capitalist tenant, the relation being a mere money relation fixed by contract. This transforms also the nature of the rent, not merely in fact and accidentally, as it did sometimes even under the preceding forms, but normally, by transforming its acknowledged and prevailing mode. Instead

of continuing as the normal form of surplus-value and surplus labor, it becomes a mere surplus of this surplus labor over that portion of it, which is appropriated by the exploiting capitalist in the form of profit. And now the total surplus labor, both profit and surplus above the profit, are extracted by him directly, appropriated in the form of the surplus product, and turned into money. It is only the surplus portion of the surplus-value extracted by him from the agricultural laborer by direct exploitation, by means of his capital, which he turns over to the landlord as rent. How much or how little he gives away to him depends, as a rule, upon the limits set by the average profit which is realized by the capital in the non-agricultural spheres of production, and by the non-agricultural prices of production regulated by this average profit. From a normal form of surplus-value and surplus labor the rent has now transformed itself into a surplus peculiar to the agricultural sphere of production, exceeding that portion of the surplus labor, which is claimed at first hand by capital as its legitimate and normal share. Profit, instead of rent, has now become the normal form of surplus-value, and rent exists only as a form, not of surplus-value in general, but of one of its offshoots, called surplus profit, which assumes an independent existence only under very peculiar circumstances. It is not necessary to dwell any further upon the way in which this transformation is accompanied by a gradual transformation of the mode of production itself. This is shown by the mere fact that it is the normal thing for the capitalist tenant to produce the products of the soil as commodities, and that, while formerly only the surplus over his means of subsistence was converted into commodities, now but a relatively small part of these commodities is directly used as means of subsistence for him. It is no longer the land, but the capital, which has now brought under its direct sway and under its own productivity the labor of the agriculturalist.

The average profit and the price of production regulated by it are formed outside of the conditions of the rural country within the circles of city commerce and manufacture. The profit of the rent-paying farmers does not enter into it as a balancing element, for their relation to the landlord is not a capitalist one. To the extent that he makes profits, that is, realizes a surplus above his necessary means of subsistence, either by his own labor or by the exploitation of other people's labor, it is done behind the back of the normal relationship. Other circumstances being equal, the size of this profit does

not determine the rent, but on the contrary, it is determined by the limits set by the rent. The high rate of profit in the Middle Ages is not entirely due to the low composition of the capital, in which the variable capital, invested in wages, predominates. It is due also to the robbery committed against the land, the appropriation of a portion of the landlord's rent and of the income of his vassals. While the country exploits the town politically in the Middle Ages, wherever feudalism has not been broken down by an exceptional development of the towns, the town, on the other hand, everywhere and without exception exploits the land economically by its monopoly prices, its system of taxation, its guild organizations, its direct mercantile fraud and its usury.

One might imagine that the mere advent of the capitalist tenant in agricultural production would prove that the price of those products of the soil, which had always paid a rent in one form or another, must stand above the prices of production of manufacture, at least at the time of this advent. And this for the reason that the price of such products of the soil had reached the level of a monopoly price or that it had risen as high as the value of the products of the soil, and that this value actually stood above the price of production regulated by the average profit. Unless this were so, the capitalist tenant could not very well realize first the average profit out of the price of these products, at the existing prices of the products of the soil, and then pay out of this same price a surplus above his profit in the form of rent. One might conclude from this that the average rate of profit, which guides the capitalist tenant in his contract with the landlord, had been formed without including the rent, and that as soon as this average rate of profit assumes a regulating part in agricultural production it finds this surplus ready at hand and turns it over to the landlord. It is in this traditional manner that, for instance, Rodbertus explains this matter.

But several points must be considered here.

This advent of capital as an independent and leading power in agriculture does not take place generally all at once, but gradually and separately in various lines of production. It seizes at first, not agriculture proper, but such lines of production as cattle raising, especially sheep raising, whose principal product, wool, offers a steady surplus of the market price over the

price of production during the rise of industry, and this is not balanced until later. This was the case in England during the 16th century.

Since this capitalist production appears at first but sporadically, nothing can be argued against the assumption, that it takes hold in the beginning only of such groups of land as are able, through their particular fertility, or their exceptionally favorable location, to pay a differential rent in the long run.

Even assuming that at the time of the advent of this mode of production, which indeed requires an increasing preponderance of the demand in the towns, the prices of the products of the soil stood higher than the price of production, as was doubtless the case during the last third of the 17th century in England, nevertheless, as soon as this mode of production will have worked its way somewhat out of the mere subordination of agriculture to capital, and as soon as the improvement of agriculture and the reduction of its cost of production, which accompany its development, will have taken place, the balance will be restored by a reaction, a fall in the price of the products of the soil, as happened in the first half of the 18th century in England.

In this traditional way, then, rent as a surplus above the average profit cannot be explained. Whatever may be the historical circumstances of the time in which rent appears at first, once that it has taken root it cannot exist under any other modern conditions than those previously explained.

Finally, it should be noted in the transformation of rent in kind into money rent, that with it capitalized rent, or the price of land, and its salableness and sale become essential elements, and that with them not only the formerly rent-paying tenant may be transformed into an independent peasant proprietor, but also urban and other moneyed people may buy real estate, in order to lease them either to peasants or to capitalists and thus to enjoy rent in the form of interest on capital so invested; that, therefore, this likewise assists in the transformation of the former mode of exploitation, of the relation between the owner and the actual tiller of the land, and of the rent itself.

Share Farming (Metairie System) and Small Peasants' Property.

We have now arrived at the end of our line of development of ground-rent.

In all these forms of ground-rent, whether labor rent, rent in kind, or money rent (as a mere change of form of rent in kind), the rent-paying party is always supposed to be the actual tiller and possessor of the land, whose unpaid surplus labor passes directly into the hands of the landlord. Even in the last form, money rent — to the extent that it is “pure,” in other words, a mere change of form of rent in kind — this is not only possible, but actually takes place.

As a form of transition from the original form of rent to capitalist rent, we may consider the metairie system, or share farming, under which the manager (tenant) furnishes not only labor (his own or that of others), but also a portion of the first capital, and the landlord furnishes, aside from the land, another portion of the first capital (for instance cattle), and the product is divided between the tenant and the landlord according to definite shares, which differ in various countries. In this case, the tenant lacks the capital required for a thorough capitalist operation of agriculture. On the other hand, the share thus appropriated by the landlord has not the pure form of rent. It may actually include interest on the capital advanced by him and a surplus rent. It may also absorb practically all the surplus labor of the tenant, or leave to him a greater or smaller portion of this surplus labor. But the essential point is that rent no longer appears here as the normal form of surplus-value in general. On the one hand, the tenant, whether he employ his own labor or another's, is supposed to have a claim upon a portion of the product, not in his capacity as a laborer, but as a possessor of a part of the instruments of labor, as his own capitalist. On the other hand, the landlord claims his share not exclusively in his capacity as the owner of the land, but also as a lender of capital.¹⁴⁰

A remainder of the old community in land, which had been preserved after the transition to independent peasant economy, for instance in Poland and Roumania, served there as a subterfuge for accomplishing a transition to the lower forms of ground-rent. A portion of the land belongs to the individual farmers and is tilled independently by them. Another portion is

tilled collectively and creates a surplus product, which serves either for the payment of community expenses, or as a reserve in case of crop failures, etc. These last two parts of the surplus product, and finally the whole surplus product together with the land, upon which it has been grown, are gradually usurped by state officials and private individuals, and by this means the originally free peasant proprietors, whose obligation to till this land collectively is maintained, are transformed into vassals, who are compelled to perform forced labor or pay rent in kind, while the usurpers are transformed into owners, not only of the stolen community lands, but of the lands of the peasants themselves.

We need not dwell upon actual slave economy (which likewise passes through a development from the patriarchal system, working pre-eminently for home use, to the plantation system, working for the world market) nor upon that management of estates, under which the landlords carry on agriculture for their own account, own all the instruments of production, and exploit the labor of free or unfree servants, who are paid in kind or in money. In this case, the landlord and the owner of the instruments of production, and thus the direct exploiter of the laborers counted among these instruments of production, are one and the same person. Rent and profit likewise coincide then, there being no separation of the different forms of surplus-value. The entire surplus labor of the workers, which is here represented by the surplus product, is extracted from them directly by the owner of all the instruments of production, to which the land and, under the original form of slavery, the producers themselves, belong. Where capitalist conceptions predominate, as they did upon the American plantations, this entire surplus-value is regarded as profit. In places where the capitalist mode of production does not exist, nor the conceptions corresponding to it have been transferred from capitalist countries, it appears as rent. At any rate, this form does not present any difficulties. The income of the landlord, whatever may be the name given to it, the available surplus product appropriated by him, is here the normal and predominating form, under which the entire unpaid labor is directly appropriated, and the property in land forms the basis of this appropriation.

There is, furthermore, the small peasants' property. Here the farmer is the free owner of his land, which appears as his principal instrument of

production, the indispensable field of employment for his labor and his capital. No lease money is paid under this form. Rent, therefore, does not appear as a separate form of surplus-value here, although in countries, in which capitalist industry in other lines is developed, it appears as a surplus profit by comparison with other lines of production. But it is a surplus profit which, like all the rest of the product of his labor, falls into the hands of the farmer himself.

This form of property in land requires that, as was the case under the earlier forms, the rural population should have a great preponderance over the city population, so that, while capitalist production may generally prevail, it is nevertheless but relatively little developed, concentration of capitals moves in narrow circles in the other lines of production, and dissipation of capitals predominates. Under these conditions, the greater part of the rural product will have to be consumed, as a direct means of subsistence, by the producers, the farmers themselves, and only the surplus above that will pass as commodities into the commerce with the cities. Whatever may be the manner, in which the average market price of the products of the soil is regulated in this case, the differential rent, a surplus portion of the price of commodities from the superior or more favorably located lands, must evidently exist in this case just as it does under the capitalist mode of production. This differential rent would exist, even if this form should appear under social conditions, in which no general market price has as yet been developed. It appears then in the spare surplus product. Only it flows into the pocket of the farmer, whose labor realises itself under favorable natural conditions. It is precisely under this form that the assumption is correct, as a rule, that no absolute rent exists, so that the worst soil does not pay any rent. For under this form the price of land enters as an element into the actual cost of production for the farmer, since in the course of the further development of this form the price of land may have been figured, for instance in the case of a division of an estate, at a certain money value, or, in view of the continuous change in the ownership of the whole property, or of its parts, the land may have been bought by the tiller himself, largely by taking up money on a mortgage. In this way the price of land, which is nothing else but a capitalized rent, is a pre-existing condition and rent seems to exist independently of any differentiation in the fertility and location of the land. Absolute rent is conditioned either upon the

realized surplus of the value of the product above its price of production, or a monopoly price exceeding the value of the product. But since agriculture is carried on here largely as an agriculture for direct subsistence, so that the land is an indispensable field of employment for the labor and capital of the majority of the population, the regulating market price of the product will come up to its value only under extraordinary circumstances. But its value will, as a rule, stand higher than its price of production on account of the predominance of the element of living labor, although this excess of its value over its price of production will be in its turn limited by the low composition of the capital, even of that of the industries outside of agriculture, in countries with a predominance of small farmers' property. For the small farmer the limit of exploitation is not set by the average profit of the capital, if he is a small capitalist, nor by the necessity of making a rent, if he is a landowner. Nothing appears as an absolute limit for him, as a small capitalist, but the wages which he pays to himself, after deducting his actual costs. So long as the price of the product covers these wages, he will cultivate his land, and will do so often down to the physical minimum of his wages. As for his capacity as a landlord, the barrier of property is eliminated in his case, since it can exert its influence only against a capital (including labor) separated from it, by erecting an obstacle against its investment. It is true that interest on the price of land, which generally has to be paid to another, the holder of the mortgage, also forms a barrier. But this interest can be paid out of that portion of the surplus labor, which would form the profit under capitalist conditions. The rent anticipated in the price of land, and in the interest paid for it, cannot be anything else but a portion of the capitalized surplus labor of the farmer, performed by him beyond the labor indispensable for his subsistence, without realising this surplus labor in a part of the value of commodities equal to the entire average profit, and still less in a surplus profit, which would constitute a surplus above the surplus labor realised in the average profit. The rent may be a deduction from the average profit, or even the only portion of it which is realised. In order that the small farmer may cultivate his land, or may buy land for cultivation, it is therefore not necessary, as it is under a normal capitalist production, that the market price of his products should rise high enough to allow him the average profit, and still less a surplus above this average profit fixed in the form of a rent. Therefore it is not necessary that the market price should rise, either as high as the value or as high as the

price of production of his product. This is one of the causes which keeps the price of cereals lower in countries with a predominance of small farmers than in countries with a capitalist mode of production. One portion of the surplus labor of the farmers, who work under the least favorable conditions, is given to society without an equivalent and does not pass over into the regulation of the price of production or into the formation of values in general. This lower price is also a result of the poverty of the producers and by no means of the productivity of their labor.

This form of free farmers' property managing their own affairs, as the prevailing, normal, form constitutes on the one hand the economic foundation of society during the best times of classical antiquity, on the other hand it is found among modern nations as one of the forms arising from the dissolution of feudal landlordism. In this way we meet the yeomanry in England, the peasantry in Sweden, the farmers in France and Western Germany. We do not mention the colonies here, since the independent farmer there develops under different conditions.

The free ownership of the selfemploying farmer is evidently the most normal form of landed property for small scale production, that is, for a mode of production, in which the possession of the land is a prerequisite for the ownership of the product of his own labor by the laborer, and in which the agriculturist, whether he be a free owner or a vassal, always has to produce his own means of subsistence independently, as a single laborer with his family. The ownership of the soil is as necessary for the complete development of this mode of production as the ownership of the instrument is for the free development of handicraft production. This ownership forms here the basis for the development of personal independence. It is a necessary stage of transition for the development of agriculture itself. The causes which bring about its downfall show its limitations. These causes are: Destruction of rural house industries, which form its normal supplement, as a result of the development of great industries; a gradual deterioration and exhaustion of the soil subjected to this cultivation; usurpation, on the part of the great landlords, of the community lands, which form everywhere the second supplement of small peasants' property and alone enable them to keep cattle; competition, either of plantation systems or of great agricultural enterprises carried out on a capitalist scale.

Improvements of agriculture, which on the one hand bring about a fall in the prices of the products of the soil, and on the other require greater investments and more diversified material conditions of production, also contribute towards this end, as they did in England during the first half of the 18th century.

Small peasants' property excludes by its very nature the development of the social powers of production of labor, the social forms of labor, the social concentration of capitals, cattle raising on a large scale, and a progressive application of science.

Usury and a system of taxation must impoverish it everywhere. The expenditure of capital in the price of the land withdraws this capital from cultivation. An infinite dissipation of means of production and an isolation of the producers themselves go with it. Also an enormous waste of human energy. A progressive deterioration of the conditions of production and a raising of the price of means of production is a necessary law of small peasants' property. Fertile seasons are a misfortune for this mode of production.¹⁴¹

One of the specific evils of small scale agriculture, when combined with the free ownership of the land, arises from the fact that the agriculturist invests a capital in the purchase of the land. (The same applies also to the form of transition, in which the great landlord invests capital, first, for the purpose of buying land, and secondly, for the purpose of managing it as his own tenant). Owing to the changeable nature, which the land here assumes as a mere commodity, the changes of ownership increase,¹⁴² so that the land, from the point of view of the farmer, passes again into the calculation as a new investment of capital with every new generation, every division of estates, in other words, that it becomes land bought by him. The price of land here forms an overwhelming element of the individual false cost of production, or of the cost price of the product for the individual producer.

The price of land is nothing but the capitalized, and therefore anticipated, rent. If agriculture is carried on by capitalist methods, so that the landlord receives only the rent, and the tenant pays nothing for the land except his annual rent, then it is evident that the capital invested by the owner of the

land himself in the purchase of the land constitutes an interest-bearing investment of capital for him, but that it has nothing to do with the capital invested in agriculture itself. It forms neither a part of the fixed nor of the circulating capital employed here;¹⁴³ it merely secures for the buyer a title to the annual rent, but has nothing to do with the production of the rent itself. For the buyer of land pays his capital out to the one who sells the land, and the seller relinquishes his ownership of the land for this consideration. This capital does not exist any more as the capital of the buyer after that. He has not got it any longer. Therefore it does not belong to the capital, which he can invest in any way in the land itself. Whether he bought the land at a high or a low price, or whether he received it for nothing, does not alter anything in the capital invested by the tenant in his establishment, and does not make any change in the rent, but merely changes the question, whether it appears to him as interest or not as interest, or as a high or a low interest.

Take, for instance, the slavery system. The price paid for a slave is nothing but the anticipated and capitalized surplus-value or profit, which is to be ground out of him. But the capital paid for the purchase of a slave does not belong to the capital, by which profit, surplus labor, is extracted from him. On the contrary. It is capital, which the slave holder gives away, it is a deduction from the capital, which he has available for actual production. It has ceased to exist for him, just as the capital invested in the purchase of land has ceased to exist for agriculture. The best proof of this is the fact, that it does not come back into existence for the slave holder or the land owner, until he sells the slave or the land once more. Then the same condition of things holds good for the buyer. The fact that he has bought the slave does not enable him to exploit the slave without further ceremony. He is not able to do so until he invests some other capital in production by means of the slave.

The same capital does not exist twice. It does not exist one time in the hands of the seller, and a second time in the hands of the buyer of the land. It passes from the hands of the buyer to those of the seller, and that settles the matter. The buyer has then no longer any capital, but in its stead he has a piece of land. The fact that the rent produced by a real investment of capital in this land is figured by the new owner of the land as interest on a capital,

which he did not invest in the soil, but gave away as a purchase price for the land, does not alter the economic nature of the factor land in the least, any more than the fact that some one may have paid 1,000 pounds sterling for 3% consols has anything to do with the capital, out of whose revenue the interest on the national debt is paid.

In fact, the money expended in the purchase of land, like that spent for the purchase of national bonds, is merely capital in itself, just as any amount of values is capital in itself on the basis of capitalist production. It is potential capital. The thing paid for the land, like that paid for national bonds or any other purchased commodity, is a sum of money. This is capital in itself, because it may be converted into capital. It depends upon the use to which the seller puts it, whether the money obtained by him really becomes capital or not. For the buyer it can never again perform the functions of capital, any more than any other money which he has finally spent. It figures in his calculations as interest-bearing capital, because he considers the income, which he receives as rent from his land or as interest on his bonds, as interest on the money, which he paid for his title to this revenue. He cannot realise it as capital unless he sells his title again. If he does, then the new buyer assumes the same relationship in which the old one was, and the money spent in this transaction cannot transform itself into actual capital by any change of hands.

In the case of small property in land the illusion, that the land itself has value and may, therefore, pass as a capital into the price of production of the product, like a machine or raw materials, fortifies itself still more. But we have seen that the rent, and with it capitalised rent, or the price of land, can pass over into the price of the products of the soil in two cases only. The first case is that, in which the value of the products of the soil stands higher than their price of production and the market conditions enable the landlord to realise this difference; this condition of values and prices of production obtains, when the composition of the agricultural capital raises the value above the price of production. This agricultural capital has nothing to do with the capital invested in the purchase of the land. The second case is that in which a monopoly price exists. And both cases occur less under small peasants' property and small land ownership than under any other form, because production largely satisfies the producers' own wants in their case

and is carried on independently of the regulation by the average rate of profit. Even where small peasants' economy is carried on upon leased land, the lease money comprises more than under any other conditions a portion of the profit and even a deduction from the wages; this money is then only a nominal rent, not a rent representing an independent category as compared to wages and profit.

The expenditure of money-capital for the purchase of land, then, is not an investment of agricultural capital. It is a proportionate deduction from the capital, which the small farmers can employ in their own sphere of production. It reduces to that extent the size of their means of production and thereby narrows the economic basis of their reproduction. It subjects the small farmer to the money lender's extortion, since credit, in the strict meaning of the term, occurs but rarely in this sphere. It is an obstacle to agriculture, even where such a purchase takes place in the case of large estates. In fact, it contradicts the capitalist mode of production, which is on the whole indifferent to the question whether the land-owner is in debt, no matter whether he inherited or bought his estate. The management of the leased estate itself is not altered in its nature, whether the landowner pockets the rent himself or whether he has to pay it over to the holder of his mortgage.

We have seen that the price of land is regulated by the rate of interest, if the ground-rent is a given magnitude. If the rate of interest is low, then the price of land is high, and vice versa. Normally, then, a high price of land and a low rate of interest would have to go hand in hand, so that if the farmer paid a high price for the land in consequence of a low rate of interest, the same low rate of interest should also secure for him his running capital on easy terms of credit. But in reality, things turn out differently under small peasants' property, as the prevailing form. In the first place, the general laws of credit do not apply to the farmer, since these laws rest upon the capitalist as a producer. In the second place, where small peasants' property predominates — we are not speaking of colonies here — and the small peasant forms the foundation of the nation, the formation of capital, that is social reproduction, is relatively weak, and the formation of loanable money-capital, in the sense in which we have previously analyzed this term, is still weaker. For this is conditioned upon concentration and the existence

of a class of rich and idle capitalists (Massie). In the third place, where the ownership of the land is a necessary condition for the existence of the greater part of the producers, as it is here, and an indispensable field of investment for their capital, the price of land is raised independently of the rate of interest, and often in an inverse ratio to it, by the preponderance of the demand for land over its supply. If sold in small lots, the land in this case brings a far higher price than it does by its sale in large estates, because the number of small buyers is large and that of the large buyers small (Bandes Noires, Rubichon; Newman). For all these reasons the price of land rises here while the rate of interest is relatively high. The relatively low interest, which the farmer here derives from the capital invested in the purchase of land (Mounier), corresponds on the other hand to the high rate of interest exacted by usury, which he himself has to pay to his mortgage creditors. The Irish system shows the same thing, only in another form.

This price of land, an element foreign in itself to production, may here rise to such a point that it makes production impossible (Dombasle).

The fact that the price of land plays such a role, that the sale and purchase of land, the circulation of land as a commodity, develops to this degree, is a practical result of capitalist development, since a commodity is here the form generally assumed by all products and all instruments of production. On the other hand, this development takes place only wherever capitalist production develops but to a limited extent and does not bring forth all its peculiarities. For this condition rests precisely upon the fact that agriculture is no longer, or not yet, subject to the capitalist mode of production, but rather to a mode handed down from obsolete forms of society. The disadvantages of the capitalist mode of production, which makes the producers dependent upon the money price of their products, coincide here with the disadvantages due to the imperfect development of capitalist production. The farmer becomes a merchant and an industrial without the conditions which would enable him to produce his goods as commodities.

The conflict between the price of land, as an element in the cost price of the producers, but not an element in the price of production of the product (even though the rent should pass as a determining element into the price of

the products of the soil, the capitalized rent, which is advanced for 20 years or more, does not pass into their price in this way), is but one of the forms through which the antagonism between private ownership of the land and between a rational agriculture, a normal social utilization of the soil, expresses itself. But on the other hand, the private ownership of the land, and with it the expropriation of the direct producers from the land — the private property of some, which implies lack of private property on the part of others — is the basis of the capitalist mode of production.

Here, in agriculture on a small scale, the price of the land a form and result of private ownership of the land, appears as a barrier of production itself. In agriculture on a large scale, and in the case of large estates resting upon a capitalist mode of production, private ownership likewise acts as a barrier, because it limits the tenant in his investment of productive capital, which in the last analysis benefits, not him, but the landlord. In both forms the exploitation and devastation of the powers of the soil takes the place of a consciously rational treatment of the soil in its role of an eternal social property, of an indispensable condition of existence and reproduction for successive generations of human beings. And besides, this exploitation is made dependent, not upon the attained degree of social development, but upon the accidental and unequal situations of individual producers. In the case of small property this happens from lack of means and science, by which the social productivity of labor-power might be utilized. In the case of large property, it is done by the exploitation of such means for the purpose of the most rapid accumulation of wealth for the tenant and proprietor. The dependence of both of them upon the market price is instrumental in accomplishing this result.

All critique of small property resolves itself in the last resort into a critique of private ownership as a barrier and obstacle of agriculture. And so does all counter-critique of large property. In either case, we leave aside, of course, all minor considerations of politics. This barrier and this obstacle, which are set up by all private property of land against agricultural production and against a rational treatment, conservation and improvement of the soil itself, develop on both sides merely in different forms. In the controversy over these specific forms of the evil its ultimate cause is forgotten.

Small property in land is conditioned upon the premise that the overwhelming majority of the population is rural, and that not the social, but the isolated labor predominates; that, therefore, in view of such conditions, the wealth and development of reproduction, both in its material and intellectual sides, are out of the question and with them the prerequisites of a rational culture. On the other hand, large landed property reduces the agricultural population to a continually decreasing minimum, and induces on the other side a continual increase of the industrial population crowded together in large cities. In this way it creates conditions, which cause an incurable break in the interconnections of the social circulation of matter prescribed by the natural laws of life. As a result the strength of the soil is wasted, and this prodigality is carried far beyond the boundaries of a certain country by commerce (Liebig).

While small property in land creates a class of barbarians standing half way outside of society, a class suffering all the tortures and all miseries of civilized countries in addition to the crudeness of primitive forms of society, large property in land undermines labor-power in the last region, in which its primal energy seeks refuge, and in it which stores up its strength as a reserve fund for the regeneration of the vital power of nations, the land itself. Large industry and large agriculture on an industrial scale work together. Originally distinguished by the fact, that large industry lays waste and destroys principally the labor-power, the natural power, of human beings, whereas large agriculture industrially managed destroys and wastes mainly the natural powers of the soil, both of them join hands in the further course of development, so that the industrial system weakens also the laborers of the country districts, and industry and commerce supply agriculture with the means by which the soil may be exhausted.

PART VII. THE REVENUES AND THEIR SOURCES.

CHAPTER XLVIII. THE TRINITARIAN FORMULA.

I.144

CAPITAL — Profit (Profit of Enterprise plus Interest), Land — Ground-Rent, Labor — Wages, this is the trinitarian formula which comprises all the secrets of the social process of production.

Furthermore, since interest, as previously demonstrated, appear as the characteristic product of capital, and profit of enterprise distinguishes itself from interest by appearing as wages independent of capital, the above trinitarian formula reduces itself more specifically to the following: Capital — Interest, Land — Ground-Rent, Labor — Wages. Here profit, the specific mark characterizing the form of surplus-value belonging to the capitalist mode of production, is happily eliminated.

Now, if we look more closely at this economic trinity, we observe:

The alleged sources of the annually available wealth belong to widely dissimilar spheres and have not the least analogy with one another. They have about the same relation to each other as lawyer's fees, carrots, and music.

Capital, Land, Labor! But capital is not a thing. It is a definite interrelation in social production belonging to a definite historical formation of society. This interrelation expresses itself through a certain thing and gives to this thing a specific social character. Capital is not the sum of the material and produced means of production. Capital means rather the means of production converted into capital, and means of production by themselves are no more capital than gold or silver are money in themselves. Capital signifies the means of production monopolized by a certain part of society, the products and material requirements of labor made independent of labor-power in living human beings and antagonistic to them, and personified in capital by this antagonism. Capital means not merely the products of the laborers made independent of them and turned into social

powers, the products turned into rulers and buyers of their own producers, but also the social powers and the future...(illegible) form of labor, which antagonize the producers in the shape of qualities of their products. Here, then, we have a definite and, at first sight, very mystical, social form of one of the factors in a historically produced process of social production.

By the side of this factor we have the land, the unorganic nature as such, a crude and uncouth mass, in its whole primal wildness. Value is labor. Therefore surplus-value cannot be land. The absolute fertility of the soil accomplishes no more than that a certain quantity of labor produces a certain product conditioned upon the natural fertility of the soil. The difference in the fertility of the soil brings it about that the same quantities of labor and capital, hence the same value, express themselves in different quantities of agricultural products, so that these products have different individual values. The equalization of these individual values into market-values is responsible for the fact that the “advantages of fertile over inferior soil...are transferred from the cultivator or consumer to the landlord.” (Ricardo, Principles, .)

And finally, the third party in this conspiracy is a mere ghost, “Labor,” a mere abstraction, and which does not exist when taken by itself, or, if we take...(illegible), the productive activity of human beings in general, by which they promote the circulation of matter between themselves and nature, divested not only of every definiteness of social form and character, but even of its mere natural existence, independent of society, lifted above all societies, being the common attribute of unsocial man as well as of man with any form of society and a general expression and assertion of life.

II.

Capital — Interest; Private Land, Private Ownership of the Earth, in modern form and corresponding to the capitalist mode of production — Rent; Wage Labor — Wages. This is supposed to be the connection between the sources of revenue. Wage Labor and Private Land, like Capital, are historically determined social forms; one a social form of labor, the other a social form of the monopolized terrestrial globe, and both forms belong to the same economic formation of society corresponding to capital.

The first remarkable thing about this formula is that Land and Labor are placed indiscriminately by the side of Capital. The one, Capital, is a definite form of an element of production belonging to a definite mode of production having a definite cast. It is an element of production combined with and represented by a definite social form. The other two, Land on the one hand and Labor on the other, are two elements of the real labor process. In their material form they are common to all modes of production, they are the material elements of all processes of production, and have nothing to do with the social form of productive processes.

Secondly. In this formula (Capital — Interest, Land — Ground-Rent, Labor — Wages of Labor), capital, land and labor respectively appear as sources of interest (instead of profit), ground-rent and wages, and these things appear as their fruits; capital, land and labor appear as the cause, interest, ground-rent and wages as the effect; and this is done in such a way that each individual source is combined with the thing which it puts forth and produces. All three revenues, interest (instead of profit), rent, wages, are three parts of the value of the product; generally speaking they are parts of value, or, expressed in money, they are certain parts of money, certain parts of price. The formula “Capital — Interest” has indeed the least meaning of any formula of capital; still it is one of its formulæ. But how is land supposed to create value, that is, a socially defined quantity of labor, or even that particular portion of the value of its own products which forms the rent? For instance, land takes part as an agent of production, in the creation of a use-value, of a material product, of wheat. But it has nothing to do with the production of the value of wheat. To the extent that value is represented by wheat, we consider wheat merely as a definite quantity of materialized social labor, regardless of the particular substance, in which this labor is materialized, or of the particular use-value of this substance.

This is not in contradiction with the fact that, in the first place, other circumstances being equal, the cheapness or dearness of the wheat depends upon the productivity of the soil. The productivity of agricultural labor is conditioned upon natural circumstances, and the same quantity of labor is represented by many or by few products, use-values, according to the productivity of such labor. How large the quantity of labor may be, which is

materialized in one bushel of wheat, depends upon the number of bushels produced by the same quantity of labor. It depends, in this case, upon the productivity of the soil, in what proportions of product value shall be materialized. But this value is given, independently of such a distribution. Value is represented by use-value; and use-value is a prerequisite for the creation of exchange-value; but it is folly to construe an antagonism by placing upon one side a use-value, like land, and upon the other side an exchange-value, and at that some particular portion of exchange-value. In the second place...[here the manuscript stops short].

III.

Vulgar economy really does nothing else but to interpret, in doctrinaire fashion, the ideas of persons entrapped in capitalist conditions of production and performing the function of agents in such production, to systematize and to defend these ideas. We need not wonder, then, that vulgar economy feels particularly at home in the estranged form of manifestation, in which economic conditions are absurd and complete contradictions, and that these conditions appear so much more self-explanatory to it, the more their internal connection is concealed. So long as the ordinary brain accepts these conceptions, vulgar economy is satisfied. But all science would be superfluous, if the appearance, the form, and the nature of things were wholly identical. Vulgar economy has not the slightest inkling of the fact that the trinity from which it takes its departure, namely Land — Rent, Capital — Interest, Labor — Wages of Labor (or Price of Labor), are on their very face three incompatible propositions. First we have the use-value Land, which has no value, and the exchange-value Rent. Here a social relation is conceived as a thing and proportioned to nature. Two incommensurable magnitudes are supposed to be proportional to each other. Then we have Capital — Interest. If capital is conceived as a certain sum of values independently represented by money, then it is manifestly nonsense to say that a certain value shall be valued higher than its value. It is precisely in the formula Capital — Interest that all intermediate links are eliminated, and capital is reduced to its most general formula, which for this reason is inexplicable by itself and absurd. It is also for this reason that the vulgar economist prefers the formula Capital — Interest, with its occult faculty of making a value unequal to itself, to the formula of Capital —

Profit, which approaches more nearly to the actual capitalist relations. Then again, driven by the restless thought that four is not five and that 100 dollars cannot be 110 dollars, he flees from Capital as an exchange-value to the material substance of capital, to its use-value as a material requirement of labor, as machinery, raw materials, etc. By this means he succeeds in putting into the place of the first incomprehensible relation, which makes four equal to five, a wholly incommensurable one between a use-value, a thing, upon the one hand, and a definite relation of social production, surplus-value, upon the other, as he does also in the case of private property in land. As soon as the vulgar economist has arrived at this incommensurable magnitude, everything becomes clear to him, and he no longer feels the need of thinking any further. For he has arrived at what is “rational” in bourgeois conception. Finally we have Labor — Wages of Labor, or Price of Labor. This last expression, as we have shown in Volume I, contradicts on its very face the conception of value as well as of price. Price, generally speaking, is but a definite expression of value. And “Price of Labor” is just as irrational as a yellow leogarithm. But here the vulgar economist is all the more satisfied, because it brings him to the deep understanding of the bourgeois, that he pays for labor with money, and because the fact that this formula contradicts the conception of value relieves him from all obligation to understand value.

We have seen that the capitalist process of production is a historically determined form of the social process of production in general. This process is on the one hand the process by which the material requirements of life are produced, and on the other hand a process which takes place under specific historical and economic conditions of production and which produces and reproduces these conditions of production themselves, and with them the human agents of this process, their material conditions of existence and their mutual relations, that is, their particular economic form of society. For the aggregate of these relations, in which the agents of this production live with regard to nature and to themselves, and in which they produce, is precisely their society, considered from the point of view of its economic structure. Like all its predecessors, the capitalist process of production takes place under definite material conditions, which are at the same time the bearers of definite social relations maintained towards one another by the individuals in the process of producing their life's requirements. These

conditions and these relations are on the one hand prerequisites, on the other hand results and creations of the capitalist process of production. They are produced and reproduced by it. We have also seen that capital (the capitalist is merely capital personified and functions in the process of production as the agent of capital), in the social process of production corresponding to it, pumps a certain quantity of surplus labor out of the direct producer, or laborer. It extorts this surplus without returning an equivalent. This surplus labor always remains forced labor in essence, no matter how much it may seem to be the result of free contract. This surplus labor is represented by a surplus-value, and this surplus-value is materialized in a surplus product. It must always remain surplus labor in the sense that it is labor performed above the normal requirements of the producer. In the capitalist system as well as in the slave system, etc., it merely assumes an antagonistic form and is supplemented by the complete idleness of a portion of society. A certain quantity of surplus labor is required for the purpose of discounting accidents, and by the necessary and progressive expansion of the process of reproduction in keeping with the development of the needs and the advance of population, called accumulation from the point of view of the capitalist. It is one of the civilizing sides of capital that it enforces this surplus labor in a manner and under conditions which promote the development of the productive forces, of social conditions, and the creation of the elements for a new and higher formation better than did the preceding forms of slavery, serfdom, etc. Thus it leads on the one hand to a stage, in which the coercion and the monopolization of the social development (including its material and intellectual advantages) by a portion of society at the expense of the other portion are eliminated; on the other hand it creates the material requirements and the germ of conditions, which make it possible to combine this surplus labor in a higher form of society with a greater reduction of the time devoted to material labor. For, according to the development of the productive power of labor, surplus labor may be large in a small total labor day, and relatively small in a large total labor day. If the necessary labor time equals three, and the surplus labor three, then the total working day is equal to six, and the rate of surplus labor 100%. If the necessary labor is equal to nine, and the surplus labor three, then the total working day is twelve and the rate of surplus labor only 33 1/3%. Furthermore, it depends upon the productivity of labor, how much use-value shall be produced in a definite time, hence also in a definite surplus

labor time. The actual wealth of society, and the possibility of a continual expansion of its process of reproduction, do not depend upon the duration of the surplus labor, but upon its productivity and upon the more or less fertile conditions of production, under which it is performed. In fact, the realm of freedom does not commence until the point is passed where labor under the compulsion of necessity and of external utility is required. In the very nature of things it lies beyond the sphere of material production in the strict meaning of the term. Just as the savage must wrestle with nature, in order to satisfy his wants, in order to maintain his life and reproduce it, so civilized man has to do it, and he must do it in all forms of society and under all possible modes of production. With his development the realm of natural necessity expands, because his wants increase; but at the same time the forces of production increase, by which these wants are satisfied. The freedom in this field cannot consist of anything else but of the fact that socialized man, the associated producers, regulate their interchange with nature rationally, bring it under their common control, instead of being ruled by it as by some blind power; that they accomplish their task with the least expenditure of energy and under conditions most adequate to their human nature and most worthy of it. But it always remains a realm of necessity. Beyond it begins that development of human power, which is its own end, the true realm of freedom, which, however, can flourish only upon that realm of necessity as its basis. The shortening of the working day is its fundamental premise.

In a capitalist society, this surplus-value, or this surplus product (leaving aside accidental fluctuations in its distribution and considering only the regulating law of these fluctuations), is divided among the capitalists as a dividend in proportion to the percentage of the total social capital held by each. In this shape the surplus-value appears as the average profit, which falls to the share of the capital, an average profit, which in its turn is separated into profits of enterprise and interest, and which in this way may fall into the hands of different kinds of capitalists. This appropriation and distribution of the surplus-value, or surplus product, by the capital however, has its barrier in private ownership of land. Just as the active capitalist pumps surplus labor, and with it surplus-value and surplus products in the form of profit out of the laborer, so the landlord in his turn pumps a portion

of this surplus-value, or surplus product, out of the capitalist, in the shape of rent, according to the laws previously demonstrated by us.

Hence, when speaking of profit as that portion of surplus-value, which falls to the share of capital, we mean average profit (profits of enterprise plus interest), which has already been limited by deducting the rent from the aggregate profits (identical in mass with the aggregate surplus-value). That rent has been deducted in the premise here. Profits of capital (profits of enterprise plus interest) and ground-rent are merely particular constituents of surplus-value, categories, by which surplus-value is distinguished according to whether it falls into the hands of capital or of private land. This classification does not alter its nature in any way. If added together, these parts form the sum of the social surplus-value. Capital pumps the surplus labor, which is represented by surplus-value and surplus product, directly out of the laborers. To this extent it may be regarded as the producer of surplus-value. Private Land has nothing to do with the actual process of production. Its role is confined to carrying a portion of the produced surplus-value from the pockets of capital to its own. However, the landlord plays a role in the capitalist process of production, not merely by the pressure, which he exerts upon capital, nor by the fact that large property in land is a prerequisite and condition of capitalist production, seeing that it separates the laborer from the means of production, but particularly because the landlord appears as the personification of one of the most essential requirements of production.

Finally, the laborer, in his capacity as the owner and seller of his individual labor-power, receives a portion of his product under the name of wages, in which that portion of his labor is materialized, which we call necessary labor, that is, the labor required for the conservation and reproduction of his labor-power, regardless of whether the conditions of this conservation and reproduction are scanty or bountiful, favorable or unfavorable.

Whatever may be the disparity of these conditions in other respects, they all have this in common: Capital yields year after year a profit to the capitalist, land a ground-rent to the landlord, and labor-power, under normal conditions and so long as it remains a useful labor-power, a wage to the

laborer. These three parts of the total value produced annually, and the corresponding parts of the annually created total product, may be annually consumed by their respective owners, without draining the source of their reproduction (leaving aside for the present any consideration of accumulation). They are like the annually consumable fruits of a perennial tree, or rather of three trees. They form the annual revenue of three classes, the capitalist, the landlord and the laborer. They are revenues distributed at large by the active capitalist in his capacity as the direct exploiter of surplus labor and employer of labor in general. In this way the capital appears to the capitalist, the land to the landlord, and the labor-power or rather the labor itself, to the laborer (since he sells labor-power only to the extent that it is actively employed, and since the price of his labor-power, as previously shown, necessarily appears as the price of his labor under the capitalist system) as three different sources of their respective revenues, of profit, ground-rent and wages. They are so in fact in the sense that capital is for the capitalist a perennial pumping machine of surplus labor, the land for the landlord a perennial magnet attracting a portion of the surplus-value pumped out by capital, and finally, labor the continually self-renewing condition and the ever self-renewing means of acquiring a portion of the value created by the laborer and with it a part of the social product measured by this portion of value, the necessities of life, under the title of wages. They are so, furthermore, in the sense that capital fixes a portion of the value, and thus of the product, of annual labor in the form of profit, the private land fixes another portion in the form of rent, and wage labor fixes a third portion in the form of wages, and converts them by this transformation into revenues of the capitalist, the landlord, and the laborer, without, however, creating the substance itself, which is transformed into these different categories.

Their distribution rather presupposes the existence of this substance, namely the total value of the annual product, which is nothing but materialized social labor. But this is not the form, in which the matter appears to the human agents in production, to the human bearers of the various functions in the process of production. It rather appears to them reversed. We shall point out in the further course of our analysis, why this happens. Capital, ground-rent and labor appear to those human agents in production as three different, independent sources, from which arise three

different constituents of the annually produced value, and of the product, in which it exists. They fancy that not merely the different forms of this value as revenues falling to the share of particular agents in the social process of production, but this value itself arises from these sources, and with it the substance of these forms of revenue.

[Here one folio sheet of the manuscript is missing.]

...Differential rent is bound up with the relative fertility of the soil, in other words, with qualities, which arise from the soil as such. But in the first place, to the extent that it rests upon the different individual values of the products of different kinds of soil, it is determined only in the manner just mentioned; in the second place, to the extent that it rests upon the regulating general market value, which differs from the individual value, it is a social law carried through by means of competition, and this law has nothing to do either with the soil or with the different degrees of its fertility.

It might seem that a rational relation was expressed at least in the term “Labor — Wages of Labor.” But this is no more the case than it is in the term “Land — Ground-Rent.” To the extent that labor creates value, and materializes itself in the value of commodities, it has nothing to do with the distribution of this value among the different categories. And so far as it has the specifically social character of wage labor, it does not create any value. We have already shown that wages of labor, or price of labor, is but an irrational expression for the value, or price, of labor-power; and the definite social conditions, under which this labor-power is sold, have nothing to do with labor as a general agent in production. Labor is also materialized in that portion of the value of a commodity, which forms the price of labor-power in the shape of wages; it creates this portion just as it does the other portions of the product; but it does not materialize itself in this portion to any other extent, or in any other way, than it does in the portions representing rent or profit. Besides, if we regard labor as a faculty creating value, we do not look upon its concrete form as a means of production, but upon its social relation, which differs from that of wage labor.

Even the term “Capital — Profit” is not correct here. If capital is viewed in the only relation, in which it produces surplus-value, namely in its

relation to the laborer, in which it extorts surplus labor by compulsion exerted upon the wage laborer and his labor-power, then this surplus-value comprises not merely profit (profit of enterprise plus interest), but also rent, in short, the entire undivided surplus-value. Here, on the other hand, as a source of revenue, it is considered only in relation with that portion, which falls into the hands of the capitalist. This is not the surplus-value which it extracts, all together, but only that portion, which it extracts for the capitalist. Still more is all connection lost, as soon as the formula is transformed into “Capital — Interest.”

Now, having first considered the disparity of the above three sources, we must note, in the second place, that their products, their offspring, the revenues, all belong to the same sphere, namely that of value. However, this relation, not only between incommensurable magnitudes, but also between wholly unlike, mutually unrelated, and incomparable things, is accounted for by the fact that capital, like land and labor, is indeed taken only in its meaning as a material substance, that is, simply as a produced means of production, and in so doing both its relation to the laborer and its value are ignored.

In the third place, if understood in this way, the formula Capital — Interest (Profit), Land — Rent, Labor — Wages of Labor, presents a uniform and symmetrical inconsistency. In fact, when wage labor does not appear as a socially determined form of labor, but rather all labor is considered naturally as wage labor (because it appears in this light to people who are biased by capitalist conditions of production), then the particular, specific, social forms observed by the material requirements of labor (the produced means of production and the land) towards wage labor (which is in its turn a prerequisite of those conditions), easily coincide with the material existence of these requirements of labor, or with the form possessed by them generally in the actual labor process, divested of all historically determined social forms, or even of any social form. The changed form of the requirements of labor, divested of labor and facing it as an independent element, which is assumed by the produced means of production when they become capital, and by the land when it becomes monopolized land, private property, this form belonging to a definite period of history then coincides with the existence and the function of the

produced means of production and of the earth, in the general process of production. Those means of production are then capital in themselves, by nature; capital is merely an “economic name” for those means of production; and in the same way land is then naturally the earth monopolized by a certain number of landlords. Just as the products become an independent power opposed to the producer when they become capital and capitalists (for capitalists are but the personification of capital), so the land becomes personified in the landlord and likewise rises on its feet to demand, as an independent power, its share of the product created by its assistance. Thus it is not the land, which receives its due portion of its product for the reproduction and improvement of its productivity, but the landlord, who takes a share of this product and sells or wastes it. It is evident that capital is conditioned upon labor in the capacity of wage labor. But it is likewise evident that if wage labor is taken as a point of departure for labor, so that the identity of any labor with wage labor appears to be a matter of course, then capital and monopolized land must also appear as the natural form of the material requirements of production as distinguished from labor. It then appears natural for the material prerequisites of labor to be capital, and this looks like their general character necessarily arising from their function in the labor process. Capital and produced means of production thus become identical terms. In like manner land and land monopolized by private owners become identical terms. In this way the requirements of production in their assumed natural capacity of capital are considered as the source of profit, and so does the land assume the guise of the source of rent.

Labor as such, in its simple capacity as a useful productive activity, refers to the means of production, not as concerns their form due to social conditions, but rather as concerns their material substance, their capacity as material and means of labor. And they are distinguished merely as use-values, the land as an unproduced, the others as produced means of production. If, then, labor is identical with wage labor, so is the particular social form assumed by the requirements of labor in their opposition to labor identical with their material existence. The requirements of labor are then natural capital, and the land is natural private property. The formal separation of these requirements of labor from labor, the peculiar form of their independence as compared to labor, thus becomes a necessary

attribute, an inherent character, inseparable from the material conditions of production. The social character given to them in the process of capitalist production by a definite epoch of history becomes a natural character belonging to them, as it were, from time immemorial, as elements in the process of production. So it is that the respective part played by the earth as the original field of activity of labor, as the realm of natural forces, as the pre-existing armory of all objects of labor, and the other respective part played by the produced means of production (instruments, raw materials, etc.) in the general process of production, must seem to be expressed in the respective shares claimed by them as capital and private land, in other words, which are pocketed by their social representatives in the form of profit (interest) and rent, just as the laborer seems to receive in his wages that share which is due to his labor in the process of production. Rent, profit and wages thus seem to grow out of the role played by the land, the produced means of production, and the labor in the simple labor process, even when we look upon this labor process as one passing merely between man and nature, without regard to any historical determination.

It is merely the same thing in another form, when it is argued that the product, in which the labor of the wage laborer materializes itself for himself, as his income, his revenue, is just his wages, is just that portion of value (and of the social product measured by this value), which represents his wages. If wage labor is identical with any labor, then so is the wage and the product of labor, and so is the portion of value representing wages and the value created by any labor. But in this way the other portions of value, profit and rent, also become independent and separated from wages, and must seem to arise from sources of their own, which differ from that of wages and are independent of it. They must seem to arise out of the participating elements of production, by the owners of which they are claimed, so that profit seems to come from the means of production, the material elements of capital, and rent from the earth, or nature, represented by the landlord (Roscher).

Private land, capital and wage labor are thus transformed into actual sources of revenue. It is thought that rent, profit and wages and the respective portions of the product representing these parts of value, in which they exist and for which they may be exchanged, arise from these

sources directly, and that the value of the product itself arises in the last analysis from them.¹⁴⁶ They are not considered as sources of revenue in the sense that capital assigns to the capitalist, in the form of profit, a portion of the surplus-value extracted by him from labor, that monopoly in land attracts for the landlord another portion in the form of rent, and that labor gives to the laborer the remaining portion of value in the form of wages. They are not conceived as sources, by which one portion of value is transformed into profit, another into rent, a third into wages.

In the case of the simplest categories of the capitalist mode of production, and even of the production of commodities, in the case of commodities and money, we have already pointed out the mystifying character, which transforms the social conditions that use the material elements of wealth as bearers of production into qualities of these things themselves (commodities) and still more pronouncedly transforms the interrelations of production themselves into a thing (money). All forms of society, to the extent that they reach the stage in which commodities are produced and money circulated, take part in this perversion. But under the capitalist mode of production and in the case of capital, which forms its ruling category, its determining relationship in production, this enchanted and perverted world develops still more. If we consider capital in the actual process of production, as a means of extracting surplus-value, then this relationship is still very simple. The actual connection impresses itself upon the bearers of this process, the capitalists, and they are conscious of it. The violent struggle about the limits of the working day shows this clearly. But even within this undisguised sphere, the sphere of the direct process between labor and capital, matters do not rest in this simplicity. With the development of relative surplus-value in the typical, specifically capitalist mode of production, by which the social powers of production of labor are developed, these powers of production and the social interrelations of labor in the actual labor process seem transferred from labor to capital. This endows capital with a very mystic nature, since all of labor's social powers of production appear to be due to capital, not to labor as such, and seem to sprout from the womb of capital itself. Then the process of circulation intervenes, with its changes of substance and form, to which all parts of the capital, even of agricultural capital, must submit to the extent that the specifically capitalist mode of production develops. This is a sphere, in

which the conditions under which value is originally produced are pushed completely into the background. Even in the direct process of production the capitalist acts at the same time in the capacity of a producer of commodities, of a manager in the production of commodities. Hence this process of production appears to him by no means as a simple process by which surplus-value is produced. But whatever may be the surplus-value extorted by capital in the actual process of production and offered in the shape of commodities, the value and surplus-value contained in the commodities must first be realized in the process of circulation. And both the restitution of the values advanced in production and, particularly, the surplus-value contained in the commodities do not seem to be merely realized in the circulation, but actually to rise from it. This appearance of things is strengthened by two circumstances. In the first place, it is strengthened by the profit made through cheating, cunning, inside knowledge, ability and a thousand market constellations in the selling of commodities. In the second place, it is enhanced by the circumstance that a second determining element, the time of circulation, is here added to the labor time. It is true that the time of circulation asserts itself as a negative barrier against the formation of value and surplus-value, but it has the appearance of being quite as positive a cause as labor itself and of carrying into the problem a determining element independent of labor and due to the nature of capital itself.

In Volume II we had of course, to present merely the forms created and determined by this sphere of circulation, to demonstrate the further development of the form of capital, which takes place in it. But in reality this sphere is the sphere of competition, which, considered in each individual case, is dominated by accident. In other words, the internal law, which enforces itself in these accidents and regulates them, does not become visible until large numbers of these accidents are grouped together. It remains invisible and unintelligible to the individual agents in production. Furthermore: The actual process of production, considered as the unison of the strict process of production and the process of circulation, gives rise to new formations, in which the vein of the internal connections is lost, the conditions of production become separate identities, and the component parts of value become ossified into forms independent of one another.

We have seen that the conversion of surplus-value into profit is determined as much by the process of circulation as it is by the process of production. The surplus-value, in the form of profit, is no longer referred back to that portion of capital, which is invested in labor and from which it arises, but to the total capital. The rate of profit is regulated by laws of its own, which admit, or even require, a change in it while the rate of surplus-value remains unaltered. All this obscures more and more the true nature of surplus-value and thus the actual running gear of capital. Still more is this done by the transformation of profit into average profit and of the values into prices of production, into the regulating averages of the market prices. Here a complicated social process intervenes, the process by which the capitals are equalized, and which separates the relative average prices of the commodities from their values, as it separates also the average profits of the various spheres of production (quite aside from the individual investments of capital in each particular sphere of production) from the actual exploitation of labor by the different capitals. No longer does the average price of the commodities merely seem to differ from their value, but it actually does differ, it actually is not the same as the labor realised in them, and the average profit of some particular capital differs from the surplus-value, which this capital has extracted from the laborers employed by it. The value of the commodities appears no longer directly down to their very last boundaries, but remains visible only in the influence of the fluctuating productivity of labor upon the rise and fall of the prices of production. The profit seems to be determined only incidentally by the direct exploitation of labor, namely to the extent that this exploitation permits the capitalist to realize a profit differing from the average profit at the regulating market prices, which appear to be independent of such exploitation. The normal average profits themselves seem immanent in capital and independent of exploitation. The abnormal exploitation, or even the average exploitation under exceptionally favorable conditions, seems to determine only the deviations from the average profit, not this profit itself. The division of profit into profit of enterprise and interest (not to mention the intervention of commercial profit and financial profit founded upon the circulation and seemingly arising wholly from it and not at all from the process of production itself) completes the self-dependence of the form of surplus-value, the ossification of its form as compared to its substance. One portion of the profit, as compared to the other, separates itself wholly from the

relationship of capital as such and pretends to be an offspring not of the process by which wage labor is exploited, but of the wage labor of the capitalist himself. On the other hand, interest then seems to be independent both of the wage labor of the laborer and of that of the capitalist, and to arise from no other source but capital itself. Capital, appearing originally, on the surface of circulation, as a capitalist fetish, as a self-expanding value, now assumes in the form of interest-bearing capital, its most estranged and peculiar shape. For this reason the formula “Capital — Interest,” as the third link in “Land — Rent” and “Labor — Wages of Labor,” appears much more consistent than “Capital — Profit,” since in “Profit” there still remains a recollection of its origin, which is not only extinguished in “Interest,” but also placed in opposition to this origin and fixed in this antagonistic form.

Capital, as an independent source of surplus-value, is finally joined by private land, which acts as a barrier against average profit and transfers a portion of the surplus-value to a class that neither does any work of its own, nor directly exploits labor, nor can find moral consolation, like interest-bearing capital, in devotional subterfuges such as the alleged risk and sacrifice of lending money to others. Since a part of the surplus-value seems here bound up directly, not with a social relation, but with a natural element, the land, the form of the mutual estrangement and ossification of the various parts of surplus-value is completed, their internal connection completely disrupted, and its source entirely buried, because the relations of production have been made selfdependent in spite of the fact that they are bound up with the different material elements of the process of production.

In Capital — Profit, or better Capital — Interest, Land — Rent, Labor — Wages of Labor, in this economic trinity expressing professedly the connection of value and of wealth in general with their sources, we have the complete mystification of the capitalist mode of production, the transformation of social conditions into things, the indiscriminate amalgamation of the material conditions of production with their historical and social forms. It is an enchanted, perverted, topsy-turvy world, in which Mister Capital and Mistress Land carry on their goblin tricks as social characters and at the same time as mere things. It is the great merit of classic economy to have dissolved this false appearance and illusion, this self-isolation and ossification of the different social elements of wealth by

themselves, this personification of things and conversion of conditions of production into entities, this religion of everyday life. It did so by reducing interest to a portion of profit, and rent to the surplus above the average profit, so that both of them meet in surplus-value. It represented the process of circulation as a mere metamorphosis of forms, and finally reduced value and surplus-value of commodities to labor in the actual process of production. Nevertheless even the best spokesmen of classic economy remained more or less the prisoners of the world of illusion which they had dissolved critically, and this could not well be otherwise from a bourgeois point of view. Consequently all of them fall more or less into inconsistencies, half-way statements, and unsolved contradictions. On the other hand, it is equally natural that the actual agents of production felt completely at home in these estranged and irrational forms of Capital — Interest, Land — Rent, Labor — Wages of Labor, for these are the forms of the illusion, in which they move about and in which they find their daily occupation. It is also quite natural that vulgar economy, which is nothing but a didactic, more or less dogmatic, translation of the ordinary conceptions of the agents of production and which arranges them in a certain intelligent order, should see in this trinity, which is devoid of all internal connection, the natural and indubitable basis of its shallow assumption of importance. This formula corresponds at the same time to the interests of the ruling classes, by proclaiming the natural necessity and eternal justification of their sources of revenue and raising them to the position of a dogma.

In our description of the way, in which the conditions of production are converted into entities and into independent things as compared to the agents of production, we do not enter into a discussion of the manner, in which the interrelations of the world market, its constellations, the movements of market prices, the periods of credit, the cycles of industry and commerce, the changes from prosperity to crises, appear to these agents as overwhelming natural laws that rule them irresistibly and enforce their rule over them as blind necessities. We do not enter into such a discussion, because the actual movements of competition belong outside of our plan, and because we have to present only the internal organization of the capitalist mode of production, as it were, in its ideal average.

In preceding forms of society this economic mystification arises principally in the case of money and of interest-bearing capital. In the nature of the case it is out of the question where, in the first place, production is mainly for use, for the satisfaction of immediate wants, and where, in the second place, slavery or serfdom form the broad foundation of social production, as they did in antiquity and during the Middle Ages. The rule of the conditions of production over the producers in those systems is concealed by the relation between masters and servants, which appear and are visible as the direct motive powers of the process of production. In the primitive societies, in which natural communism prevails, and even in the ancient urban communes, it is this community itself which appears as the basis of production, and its reproduction appears as its ultimate purpose. Even in the medieval guild system neither capital nor labor appear untrammelled. Their relations are rather defined by the corporate rules, by the conditions connected with them, and by the conceptions of professional duties, mastership, etc., which accompany them. Only when the capitalist mode of production...

CHAPTER XLIX. A CONTRIBUTION TO THE ANALYSIS OF THE PROCESS OF PRODUCTION.

FOR the purposes of the following analysis we may leave out of consideration the distinction between the price of production and the value, since this distinction falls altogether to the ground, when, as is the case here, the value of the total annual product of labor is under discussion, in other words, the value of the product of the total social capital.

Profit (profit of enterprise plus interest) and rent are nothing but peculiar forms assumed by particular parts of the surplus-value of commodities. The magnitude of the surplus-value is the limit of the sum of parts, into which it may be divided. The average profit plus the rent are, therefore, equal to the surplus-value. It is possible that a part of the surplus labor contained in the commodities, and thus of the surplus-value, does not take part directly in the equalization tending toward an average rate of profit, so that a part of the value of commodities is not expressed at all in their price. But in the first place, this is balanced either by the fact that the rate of profit increases, when the commodities sold below their value form an element of the constant capital, or by the fact that profit and rent are represented by a larger product, when the commodities sold below their value pass over into that portion of the value which is consumed as revenue in the shape of articles for individual consumption. In the second place, the average movement strikes the balance. At any rate, even if a portion of the surplus-value is not expressed in the price and is lost so far as the formation of prices is concerned, the sum of average profit plus rent in their normal form can never be larger than the total surplus-value, although it may be smaller. Their normal form is conditioned upon wages corresponding to the value of labor-power. Even monopoly rent, to the extent that it is not a deduction from wages, and does not constitute a special category, must be indirectly always a part of the surplus-value. If it is not a part of the surplus price above the cost of production of the commodity itself, of which it is a constituent part, as in the case of differential rent, or a spare portion of the

surplus-value of the commodity itself, of which it is a constituent part, above that portion of its own surplus-value which is measured by the average profit (as in the case of absolute rent), it is at least a part of the surplus-value of other commodities, that is, of commodities which are exchanged for this commodity, which has a monopoly price.

The sum of average profit plus ground-rent can never be greater than the magnitude of which they are the parts and which exists before they are so partitioned. It is, therefore, immaterial for our discussion, whether the entire surplus-value of the commodities, that is, all the surplus labor materialized in the commodities, is realized in their price or not. The surplus labor is not entirely realized for the simple reason that, owing to the continual change in the amount of socially necessary labor for the production of a certain commodity, a change arising out of the continual change in the productive power of labor, one portion of the commodities is always produced under abnormal conditions and must, therefore, be sold below its individual value. At any rate, profit plus rent equal the total realized surplus-value (surplus-labor), and for the purposes of the present discussion the realized surplus-value may be assumed as equal to all surplus-value; for profit and rent are realized surplus-value, or generally speaking the surplus-value which passes into the prices of commodities, which is practically all the surplus-value forming a constituent part of this price.

On the other hand, the wages, which are the third significant form of revenue, are always equal to the variable portion of capital, which is the portion invested, not in means of production, but in the purchase of living labor-power, in the payment of laborers. (The labor paid in the expenditure of revenue is itself paid in wages, profit, or rent, and therefore does not form any portion of the value of commodities by which it is paid. Hence it is not considered in the analysis of the value of commodities and of the component parts into which it is divided.) Wages are the materialization of that portion of the total working day of the laborer, in which the value of the variable capital and thus the price of labor is reproduced. It is that portion of the value of commodities, in which the laborer reproduces the value of his own labor-power, or the price of his labor. The total working day of the laborer is divided into two parts. One portion is that in which he performs the amount of labor necessary to reproduce the value of his own means of

subsistence. It is the paid portion of his total labor, that portion which is necessary for his own maintenance and reproduction. The entire remaining portion of the working day, the entire surplus quantity of labor performed above the value of the labor realized in his wages, is surplus labor, unpaid labor, represented by the surplus-value of his entire product in commodities (and thus by a surplus quantity of commodities), surplus-value, which in its turn is divided into differently named parts, into profit (profit of enterprise plus interest) and rent.

The entire portion of the value of commodities, then, in which the total labor of the laborers added during one day, or one year, is realized, is divided into the value of wages, into profit and into rent. For this total labor is divided into necessary labor, by which the laborer creates that portion of the value of his product, with which he is himself paid, that is, his wages, and into unpaid surplus labor, by which he creates that portion of the value of the product, which represents surplus-value and which is later divided into profit and rent. Aside from this labor the laborer does not perform any labor, and he does not create any value outside of the total value of the product, which assumes the forms of wages, profit and rent. The value of the annual product, in which the new labor added by the laborer during the year is incorporated, is equal to the wages, or the value of the variable capital, plus the surplus-value, which in its turn is divided into profit and rent.

The entire portion of the value of the annual product, then, which the laborer creates in the course of the year, is expressed in the annual sum of the values of the three revenues, the values of wages, profit, and rent. Evidently, therefore, the value of the constant portion of capital is not reproduced in the value of the annually created product, for the wages are only equal to the value of the variable portion of capital advanced in production, and rent and profit are only equal to the surplus-value, the produced excess of value above the total value of the advanced capital, which is equal to the value of the constant plus the value of the variable capital.

It is immaterial for the difficulty to be solved here that a portion of the surplus-value converted into the form of profit and rent is not consumed as

revenue, but is accumulated. That portion, which is saved up as a fund for accumulation, serves for the formation of new, additional, capital, but not for the reproduction of the old capital, neither of that portion of the old capital which is invested in wages nor of that which is invested in means of production. We may, therefore, assume here for the sake of simplicity that the revenues pass wholly into individual consumption. The difficulty has a twofold aspect. On the one hand, the value of the annual product, in which these revenues, wages, profit and rent, are consumed, contains a portion of value, which is equal to the portion of value of the constant part of capital used up in it. It contains this portion of value in addition to the other portion, which resolves itself into wages and that which resolves itself into profit and rent. Its value is therefore equal to wages plus profit plus rent plus C (its constant portion of value). How can an annually produced value, which equals only wages plus profit plus rent, buy a product which has a value of wages plus profit plus rent plus C?

How can the annually produced value buy a product, which has a higher value than its own?

On the other hand, if we leave aside that portion of the constant capital which did not pass over into the product, and which, therefore, continues to exist after the annual production of commodities as it did before it; in other words, if we leave aside the employed, but not consumed fixed capital, we find that the constant portion of the advanced capital has been wholly transferred to the new product in the shape of raw and auxiliary materials, whereas a part of the instruments of labor has been wholly consumed and another part of them only partially, so that only a part of its value has been consumed in production. This entire portion of the constant capital, which has been consumed in production, must be reproduced in its natural form. Assuming all other circumstances, particularly the productive power of labor, to remain unchanged, this portion requires for its reproduction the same amount of labor as before, that is, it must be replaced by its equivalent in value. If it is not, then reproduction itself cannot take place on the old scale. But who is going to perform this labor, and who performs it?

In the first question, to-wit, Who is going to pay for the constant portion of value, and with what? it is assumed that the value of the constant capital

consumed in production reappears as a part of the value of the product. This does not contradict the assumptions of the second difficulty. For we have demonstrated already in Volume I, Chapter VII (The Labor Process and the Process of Producing Surplus-Value), that the mere addition of new labor, although it does not reproduce the old value, but creates merely an addition to it, creates only additional value, still preserves at the same time the old value in the product; that this is done, however, by labor, not to the extent that it is a labor producing value, labor in general, but in its function as a definite productive labor. Therefore no additional labor was necessary for the purpose of preserving the value of the constant portion in the product, in which the revenue, that is, the entire value created during the year, is expended. On the other hand, it requires new additional labor to replace the value and use-value of the constant capital consumed during the past year, for unless this is replaced no reproduction is possible at all.

All newly added labor is represented in the value newly created during the year, and this is divided into the three revenues, that is, into wages, profit and rent. On the one hand, then, no spare social labor remains for the reproduction of the consumed constant capital, which must partially be replaced in its natural form and its value, and partially merely in its value (for the mere wear and tear of fixed capital). On the other hand, the value annually created by labor, divided into wages, profit and rent, and to be spent in these forms, does not suffice to pay for, or buy, the constant portion of capital, which must be contained in the annual product outside of itself.

We see, then, that the problem presented here has already been solved in the discussion of the reproduction of the total social capital, Volume II, Part III. We return to it here, in the first place, for the reason that the surplus-value had not been developed in that volume into its revenue forms, profit (profit of enterprise plus interest) and rent and, therefore, could not be treated in these forms; in the second place, because the formula of wages, profit and rent is connected with an incredible aberration of the analysis, which pervades the entire political economy since Adam Smith.

In Volume II we divided all capital into two great classes: Class I, producing means of production, and Class II, producing articles of

individual consumption. The fact that certain products may serve as well for personal consumption as for means of production (a horse, cereals, etc.), does not invalidate the absolute correctness of this division in any way. It is, in fact, no hypothesis, but merely the expression of a fact.

Take the annual product of a certain country. One portion of the product, whatever may be its ability to serve as means of production, passes over into individual consumption. It is the product for which wages, profit and rent are spent. This product is the product of a definite section of the social capital. It is possible that this same capital may also produce products belonging to Class I. To the extent that it does that, it is not the portion of capital consumed in the shape of the product of Class II, a product belonging actually to individual consumption, which supplies the productively consumed products passing into Class I. This entire product II, which passes into individual consumption, and for which the revenue is spent, is the material form of the capital consumed in it plus the produced surplus. It is also the product of a capital invested in the mere production of articles of consumption. And in the same way section I of the annual product, which serves as means of reproduction and consists of raw materials and instruments of labor, is the product of a capital invested in the mere production of means of production. By far the greater part of the products forming the constant capital exists also materially in a form, in which it cannot pass into individual consumption. To the extent that it might be so used, for instance, to the extent that a farmer might eat his seed corn, butcher his teaming cattle, etc., the economic barrier puts him into the same position in which he would be if this portion did not have a consumable form.

We have already said that we leave out of consideration, in both classes, the fixed part of the constant capital, which continues to exist so far as its material substance and value are concerned, independently of the annual product of both classes.

In Class II, consisting of products for which wages, profit and rent are spent and the revenues thus consumed, the product consists of three parts, so far as its value is concerned. One part is equal to the value of the constant portion of capital consumed in production; a second part is equal to

the value of the variable capital invested in wages; finally, a third part is equal to the value of the produced surplus-value, that is, equal to profit plus rent. The first part of the product of Class II, the value of the constant portion of capital, cannot be consumed either by the capitalists of Class II, or by the laborers of this class, or by the landlords. It does not form any part of their revenues, but must be replaced in its natural form, and must be sold in order that this may be done. On the other hand, the other two parts of this product are equal to the value of the revenues created in this class, equal to wages plus profit plus rent.

In Class I the product consists of the same parts, so far as its form is concerned. But that part, which here forms revenue, wages plus profit plus rent, in short, the variable portion of capital plus the surplus-value, is not consumed here in the natural form of the products of this Class I, but in products of the Class II. The value of the revenues of Class I must, therefore, be consumed in the shape of that portion of the products of Class II, which forms the constant capital of II, that must be reproduced. That portion of the product of Class II, which must reproduce its constant capital, is consumed in its natural form by the laborers, the capitalists and the landlords of Class I. They spend their revenues for this product of II. On the other hand, the product of I, to the extent that it represents a revenue of Class I, is productively consumed in its natural form by Class II, whose constant capital it replaces in its natural form. Finally, the consumed constant portion of the capital of Class I is replaced out of the products of this class itself, which consist of instruments of labor, raw and auxiliary materials, either by an exchange of the capitalists of I among themselves, or in such a way that a portion of these capitalists can use their own product once more as means of production.

Let us take the diagram used in Volume II, Chapter XX, II, for simple reproduction:

$$\begin{aligned} 4000 \text{ c} + 1000 \text{ v} + 1000 \text{ s} &= 6000 \\ 2000 \text{ c} + 500 \text{ v} + 500 \text{ s} &= 3000, \text{ Total } 9000. \end{aligned}$$

According to this, the producers and landlords of II consume $500 \text{ v} + 500 \text{ s} = 1,000$ as revenue; $2,000 \text{ c}$ remain to be reproduced. This is

consumed by the laborers, capitalists and rent owners of I, whose income is $1,000 v + 1,000 s = 2,000$. The consumed product of II is consumed as a revenue by I, and that portion of the revenue of I, which represents an unconsumable product, is consumed as a constant capital by II. It remains to account for the 4,000 c of I. This is replaced out of the product of I itself, which is 6,000, or rather 6,000 minus 2,000, for these last 2,000 have already been converted into constant capital of II. It should be noted that these numbers have been chosen at random, and so the proportion between the value of the revenues of I and the value of the constant capital of II also appears arbitrary. But it is evident that so far as the process of reproduction is normal and takes place under otherwise unchanged circumstances, leaving aside the question of accumulation, the sum of the values of wages, profit and rent in Class I must be equal to the value of the constant portion of the capital of Class II. Otherwise Class II will not be able to reproduce its constant capital, or Class I will not be able to convert its revenue from unconsumable into consumable articles.

The value of the annual product in commodities, just like the value of the commodities produced by some particular investment of capital, and like the value of any individual commodity, resolves itself into two parts: Part A, which replaces the value of the advanced constant capital, and Part B, which presents itself in the form of wages, profit and rent. This last part of value, B, stands in opposition to the Part A to the extent that this Part A, under otherwise equal circumstances, in the first place never assumes the form of revenue, and in the second place always flows back in the form of capital, and of constant capital at that. The other portion, B, however, carries within itself an antagonism. Profit and rent have this in common with wages that all three of them are forms of revenue. Nevertheless they differ essentially from each other in that profit and rent are surplus-value, unpaid labor, whereas wages are paid labor. That portion of the value of the product, which represents spent wages and reproduces wages, and must be reconverted into wages under the conditions assumed by us, flows back first in the shape of variable capital, as a portion of the capital that once more must be advanced for the purposes of reproduction. This portion has a double function. It exists first in the form of capital and is exchanged as such for labor-power. In the hands of the laborer it is converted into revenue, which he draws out of the sale of his labor-power, and as revenue

it is spent for means of subsistence and consumed. This double process is revealed through the intervention of money circulation. The variable capital is advanced in money, paid out as wages. This is its first function as capital. It is converted into labor-power and transformed into the expression of labor-power, into labor. This is the capitalist's side of the process. In the second place, the laborers buy with this money a part of the commodities produced by them, which part is measured by this money, and is consumed by them as revenue. If we imagine the circulation of money to be eliminated, then a part of the product of the laborer is in the hands of the capitalist in the form of existing capital. He advances this part as capital, hands it over to the laborer for new labor-power, while the laborer consumes it directly or indirectly by means of exchange for other commodities, as his revenue. That portion of the value of the product, then, which is destined in the course of reproduction to be converted into wages, into revenue for the laborers, flows back at first into the hands of the capitalist in the form of capital, more accurately of variable capital. That it should flow back in this form is an essential requirement, in order that labor as wage labor, the means of production as capital, and the process of production itself as a capitalist process may always be reproduced.

In order to avoid useless difficulties, it is necessary to distinguish the gross output and the net output from the gross income and the net income.

The gross output, or the gross product, is the total reproduced product. With the exception of the employed but not consumed portion of the fixed capital, the value of the gross output, or of the gross product, is equal to the value of the capital advanced and consumed in production, that is, the constant and variable capital plus the surplus-value, which resolves itself into profit and rent. Or, if we consider the product of the total social capital instead of that of some individual capital, the gross output is equal to the material elements forming the constant plus variable capital, plus the material elements of the surplus product, in which profit and rent are materialized.

The gross income is that portion of value and that portion of the gross product measured by it, which remains after deducting that portion of value and that portion of the total product measured by it, which replaces the

constant capital advanced and consumed in production. The gross income, then, is equal to the wages (or to that portion of the product which is to become once more the income of the laborer) plus the profit plus the rent. On the other hand, the net income is the surplus-value, and thus the surplus product, which remains after the deduction of the wages, and which, in fact, represents the surplus-value realized by capital and to be divided with the landlords, and the surplus product measured by it.

Now we have seen that the value of each individual commodity and the value of the total commodities produced by each individual capital is divided into two parts, one of which replaces only constant capital, and the other of which, although a part of it flows back as variable capital, that is, also in the form of capital, nevertheless is destined to be wholly transformed into a gross income, and to assume the form of wages, profit and rent, the sum of which makes up the gross income. We have also seen that the same is true of the value of the annual total product of a certain society. There is only this difference between the product of the individual capitalist and that of society: From the point of view of the individual capitalist the net income differs from the gross income, for this last includes the wages, whereas the first excludes them. Viewing the income of the whole society, the national income consists of wages plus profit plus rent, that is, of the gross income. But even this is an abstraction to the extent that the entire society, on the basis of capitalist production, places itself upon the capitalist standpoint and considers only the income divided into profit and rent as the net income.

On the other hand, the dream of men like Say, to the effect that the entire output, the entire gross output, resolves itself into the net income of the nation and cannot be distinguished from it, so that this distinction disappears from the national point of view, is but the necessary and ultimate expression of the absurd dogma pervading political economy since Adam Smith, that the value of commodities resolves itself in the last analysis into an income, into wages, profit and rent.¹⁴⁷

Of course, it is very easy to understand, in the case of each individual capitalist, that a portion of his product must be reconverted into capital (even aside from an expansion of reproduction, or accumulation), not only

into variable capital, which is destined to become in its turn an income for the laborers, a form of revenue, but also into constant capital, which can never be converted into revenue. The simplest observation of the process of production shows this clearly. The difficulty does not begin, until the process of production is studied as a whole. The fact has to be faced that the value of the entire portion of the product, which is consumed in the form of wages, profit and rent (immaterial whether the consumption is individual or productive), resolves itself under analysis wholly into a sum of values formed by wages plus profit plus rent, that is, into the total value of the three revenues, although the value of this portion of the product quite as well as that which does not pass over into the revenues contains a portion of value, equal to C, equal to the value of the constant capital contained in it, which on its very face cannot be limited by the value of the revenue. On the one hand we have the practically irrefutable fact, on the other hand the equally undeniable theoretical contradiction. This difficulty is most easily circumvented by the assertion that the value of commodities contains another portion of value, differing only seemingly, from the one existing in the form of revenue only from the point of view of the individual capitalist. The phrase that a thing is revenue for one man and capital for another saves all further thought. But then it remains an insoluble riddle, how the old capital is to be replaced, when the value of the entire product can be consumed as revenue; and how it is that the value of the product of each individual capital can be equal to the sum of the values of the three revenues plus C, the constant capital, whereas the sum of the values of the products of all capitals can be equal to the sum of the values of the three revenues plus zero. And the riddle must be solved by declaring that any analysis is incapable of finding out the simple elements of price, and must be satisfied with the faulty cycle and the progress into infinity. So that the thing which appears as constant capital may be resolved into wages, profit and rent, whereas the values of the commodities, in which wages, profit and rent are materialized, are determined in their turn by wages, profit and rent, and so forth to infinity.¹⁴⁸

The entirely false dogma to the effect that the value of commodities resolves itself in the last analysis into wages plus profits plus rent expresses itself in the assertion that the consumer must ultimately pay for the total value of the total product, or that the money circulation between producers

and consumers must ultimately be equal to the money circulation between the producers themselves (Tooke). All these assertions are as false as the axiom upon which they are founded.

The difficulties, which lead to this false and *prima facie* absurd analysis, are briefly the following:

The first difficulty is that the fundamental relationship of constant and variable capital, hence also the nature of surplus-value, and with them the entire basis of the capitalist mode of production, are not understood. The value of each portion of any product of capital contains a certain portion of value equal to the constant capital, another portion of value equal to the variable capital (converted into wages for the laborer), and another portion of value equal to surplus-value (which later on becomes profit and rent). How is it possible that the laborer with his wages, the capitalist with his profit, the landlord with his rent, should be able to buy commodities, each one of which contains not only one of these elements, but all three of them, and how is it possible that the sum of the values of wages, profit and rent, that is, of the three sources of revenue together, should be able to buy the commodities passing over into the total consumption of the recipients of these incomes, since these commodities contain another portion of value, namely constant capital, outside of the other portions of value? How can they buy a value of four with a value of three?¹⁴⁹

We have given our analysis in Volume II, Part III.

The second difficulty is that the way, in which labor, by adding a new value, preserves old value in a new form without producing this old value anew, is not understood.

The third difficulty is that the connections of the process of reproduction are not understood, as it presents itself, not from the point of view of individual capital, but from that of the total capital. The difficulty is to explain how it is that the product, in which wages and surplus-value, in short the entire value produced by all the labor newly added during the current year, can be converted into money, can reproduce the constant part of its value and yet at the same time resolve itself into a value confined

within the limits of the revenues; and how it is that the constant capital consumed in production can be replaced by the substance and value of new capital, although the total sum of the newly added labor is realized only in wages and surplus-value, and is fully represented by the sum of the values of both. It is here where the main difficulty lies, in the analysis of reproduction and of the proportions of its various component parts, both as concerns their material substance and the proportions of their value.

To these difficulties is added another one, which is intensified still more as soon as the various component parts of the surplus-value appear in the form of revenues independent of each other. This is the difficulty that the fixed marks of revenue and capital are interchanged and occupy different places, so that they seem to be merely relative determinations from the point of view of the individual capitalist and to disappear as soon as the total process of production is viewed as a whole. For instance, the revenue of the laborers and capitalists of Class I, which produces constant capital, replaces the value and the substance of the constant capital of the capitalists of Class II, which produces articles of consumption. One may, therefore, get around the difficulty by means of the conception that the thing which is revenue for one is capital for another. This promotes the idea that these functions have nothing to do with the actual peculiarities of the component parts of value in the commodities. Furthermore: Commodities which are ultimately intended for the purpose of forming the substantial elements in the expenditure of revenue, in other words, articles of consumption, pass through various stages during the year, such as woolen yarn, cloth. In the one stage they form a portion of the constant capital, in the other they are consumed individually, and thus pass wholly into the revenue. One may, therefore, imagine with Adam Smith that the constant capital is but seemingly an element of the value of commodities, which disappears in the total interrelation. Furthermore, a similar exchange takes place between variable capital and revenue. The laborer buys with his wages that portion of the commodities which form his revenue. In this way he creates at the same time for the capitalist the money form of the variable capital. Finally: One portion of the products, which form constant capital, is replaced in its natural form or by means of exchange by the producers of the constant capital themselves. The consumers have nothing to do with this process. When this is overlooked the impression is created that the revenue of the

consumers replaced the entire product, even the constant portion of its value.

Aside from the confusion created by the transformation of the values into prices of production, another confusion is due to the transformation of surplus-value into different, separate, independent forms of revenue traced back to different elements of production, into profit and rent. It is forgotten that the values of commodities are the basis, and that the division of the values of commodities into separate portions, and the further development of these portions of value into forms of revenue, their transmutation into relations of the various owners of the different agencies in production to these parts of value, their distribution among these owners according to definite categories and titles, does not alter anything in the determination of value or in its law. Neither is the law of value changed by the fact that the equalization of profit, that is, the distribution of the total value among the various capitals, and the obstacles, which private land to some extent puts in the way of this equalization (in absolute rent), makes the regulating average prices different from the individual values of the commodities. This again affects merely the addition of the surplus-value to the different prices of commodities, but does not abolish the surplus-value itself, nor the total value of commodities in its capacity as the source of these different constituents of value.

This is the confusion, which we shall consider in our next chapter, and which is necessarily connected with the illusion that the value arises out of its own component parts. First the various component parts of value receive independent forms in the revenues, and in their capacity as revenues they are referred back to the particular substantial elements of production as their alleged sources instead of to the values of commodities, which are their real source. They are actually referred back to those sources, not as components of value, but as revenues, as components of value falling to the share of definite classes of agents in production, the laborer, the capitalist and the landlord. But one might imagine that these parts of value, instead of arising out of the distribution of the value of commodities, rather form it by their composition, and this leads to that nice and faulty circle, which makes the value of commodities arise out of the sum of the values of wages, profit,

rent, and the value of wages, profit and rent, in their turn, is to be determined by the value of commodities, etc.¹⁵⁰

Considering reproduction in its normal condition, only a part of the newly added labor is employed for production and thus for the reproduction of the constant capital. This is precisely the portion which replaces the constant capital used up in the production of articles of consumption, of substantial parts of the revenue. This is balanced by the fact that this constant portion does not require any additional labor on the part of Class II. Looking upon the total process of reproduction as a whole, in which this equalising exchange between Classes I and II is included, this constant capital is not a product of newly added labor, although the product of this labor could not be created without that capital. This constant capital, looking upon it from the point of view of substance, is exposed to certain accidents and dangers in the process of reproduction. (Furthermore, considering it from the point of view of value, it may be depreciated through a change in the productive power of labor; but this refers only to the individual capitalist.) Accordingly a portion of the profit, of surplus-value and of the surplus-product, in which only newly added labor is represented, so far as its value is concerned, serves as an insurance fund. In this case it does not matter, whether this insurance fund is managed by separate insurance companies or not. This is the only part of the revenue which is neither consumed as such nor serves necessarily as a fund for accumulation. Whether it actually serves in the accumulation, or covers merely a shortage in reproduction, depends upon accident. This is also the only portion of the surplus-value and surplus-product, and thus of surplus-labor, which would continue to exist, outside of that portion which serves for accumulation and for the expansion of the process of reproduction, even after the abolition of the capitalist system. This, of course, is conditioned upon the premise that the portion regularly consumed by the direct producers does not remain limited to its present minimum. Outside of the surplus-labor for those, who on account of age can not yet or no longer take part in production, all surplus labor for non-workers would disappear. If we transport ourselves back to the beginnings of society, we find no produced means of production, hence no constant capital, the value of which could pass into the product, and which would have to be replaced in its natural form out of the product in reproduction on the same scale, and to a degree

measured by its value. But nature there supplies immediately the means of subsistence, which do not have to be produced. For this reason nature gives to the savage having but few wants the time, not to use non-existing means of production in new production, but to transform, outside of the labor required for the appropriation of naturally existing means of production, other products of nature into means of production, bows, stone knives, boats, etc. This process among savages, considered merely from the side of its substance, corresponds to the reconversion of surplus-labor into new capital. In the process of accumulation, this conversion of the product of surplus labor into capital takes place continually; and the fact that all new capital arises out of profit, rent, or other forms of revenue, that is, out of surplus labor, leads to the mistaken idea that all value of commodities arises from some revenue. On the other hand, this reconversion of profit into capital rather shows on closer analysis, that the additional labor, which is always represented in the form of revenue, does not serve for the conservation, or reproduction, of the old capital, but for the creation of new surplus capital to the extent that it is not consumed as revenue.

The whole difficulty arises from the fact that all newly added labor, to the extent that the value created by it is not dissolved into wages, appears as profit, that is, as a value which does not cost the capitalist anything and therefore cannot make good some capital advanced by him. This value rather exists in the form of available additional wealth, or, from the point of view of the individual capitalist, in the form of his revenue. But this newly created value can just as well be consumed productively as individually, equally well as capital and as revenue. In view of its natural form, some of it must be productively consumed. It is, therefore, evident that the annually added labor creates capital as well as revenue; this becomes evident in the process of accumulation. That portion of the labor-power, which is employed in the creation of new capital (analagous to that portion of the working day of a savage employed, not for the appropriation of subsistence, but for the manufacture of tools by which to appropriate subsistence), becomes evident in the fact that the entire product of surplus labor presents itself at first in the shape of profit; this use of it has indeed nothing to do with this surplus-product itself, but refers merely to the private relation of the capitalist to the surplus-value pocketed by him. In fact, the surplus-value created by the capitalist is divided into revenue and capital, that is,

into articles of consumption and additional means of production. But the old constant capital, which was handed over from last year (outside of the portion that was injured and to that extent destroyed, in short, the old constant capital that does not have to be reproduced, and so far as there is any break in the process of reproduction, the insurance covers that), so far as its value is concerned, is not reproduced by the newly added labor.

We see, furthermore, that a portion of the newly added labor is continually absorbed in the reproduction and replacement of consumed constant capital, although this newly added labor resolves itself altogether in revenues, in wages, profit and rent. But it is always overlooked, 1) that one portion of the value of this new labor is not a product of this new labor, but previously existing and consumed constant capital; that the portion of the product, in which this part of value presents itself, cannot be converted into revenue, but replaces the means of production of this constant capital in their natural form. 2) It is overlooked that the portion of value, in which this newly added labor is actually represented, is not consumed as revenue in its natural form, but replaces the constant capital in another sphere, where it is moulded into a natural form, in which it may be consumed as revenue, but which in its turn is not wholly a product of newly added labor.

To the extent that reproduction takes place on the same scale, every consumed element of the constant capital must be replaced by a new natural specimen of the same kind, if not in quantity and form, then at least in natural effectiveness. If the productive power of labor remains the same, then this natural replacement implies the reproduction of the same value, which the constant capital had in its old form. But if the productive power of labor is increased, so that the same substantial elements may be reproduced with less labor, then a smaller portion of value of this product can completely replace the constant part in its natural shape. The surplus may then be employed in the formation of additional capital, or a larger portion of the product may be given the form of articles of consumption, or the surplus labor may be reduced. On the other hand, if the productive power of labor decreases, then a larger portion of the product must be used for the replacement of the old capital; the surplus product decreases.

The reconversion of profit, or of any form of surplus-value, into capital shows — without considering the historically defined economic form and looking upon it merely as a simple formation of new means of production — that the condition still continues, in which the laborer performs surplus labor for the purpose of producing means of production, outside of the labor by which he acquires his means of subsistence. Transformation of profit into capital signifies merely the employment of a portion of the surplus labor in the formation of new, additional, means of production. That this takes place in the shape of a conversion of profit into capital, signifies merely that not the laborer, but the capitalist has control of the surplus labor. That this surplus labor must first pass through a stage, in which it appears as revenue (whereas in the case of a savage it appears as surplus labor aiming directly at the manufacture of means of production), means simply that this labor, or its product, is appropriated by the non-laborer. But what is actually converted into capital, is not the profit as such. Transformation of surplus-value into capital signifies merely that the surplus-value and the surplus-product are not consumed individually as revenue of the capitalist. What is actually so converted is the value, the materialized labor, that is, the product in which this value directly presents itself, or for which it is exchanged after having been converted into money. Even when the profit is reconverted into capital, it is not this definite form of surplus-value, not the profit, which is the source of the new capital. The surplus-value is merely changed from one form into another. But it is not this change of form which gives it the character of capital. It is the commodity and its value, which now perform the function of capital. But that the value of the commodity is not paid for — and only by this means does it become surplus-value — is quite immaterial for the materialization of labor, for value itself.

The misunderstanding expresses itself in various forms. For instance, it is said that the commodities, of which the constant capital consists, also contain elements of wages, profit and rent. Or, that the thing, which is revenue for the one, is capital for some one else, and that these are but subjective relations. Thus the yarn of the spinner contains a portion of value representing profit for him. If the weaver buys the yarn, he realizes the profit of the spinner, but for himself this yarn is merely a part of his constant capital.

Aside from the remarks made on this score concerning the relations between revenue and capital, we add the following observations: The value which passes with the yarn as a constituting element into the capital of the weaver, is the value of the yarn. In what manner the parts of this value have resolved themselves for the spinner into capital and revenue, or, in other words, into paid and unpaid labor, is immaterial for the determination of the value of the commodity itself (aside from modifications by the average profit). Back of this lurks the idea that the profit, or the surplus-value in general, is a surplus above the value of the commodity, which can be made only by raising the price, by mutual cheating, by making a gain through sale. When the price of production is paid, or the value of the commodity, this pays, naturally, also for those portions of the value of commodities, which present themselves to the seller in the shape of revenue. Of course, we are not speaking of monopoly prices here.

In the second place, it is quite correct to say that the component parts of a commodity which make up the constant capital, like any other value of commodities, may be reduced to parts of value, which resolve themselves for the producers and the owners of the means of production into wages, profit and rent. This is merely a capitalist form of expression for the fact that all value of commodities is but the measure of the socially necessary labor contained in the commodities. But we have already shown in Volume I, that this does not prevent a separation of the produced commodities of any capital into separate parts, of which the one represents exclusively the constant portion of capital, another the variable portion of capital, and a third one only surplus-value.

Storch expresses the opinion of many others, when he says: "The salable products, which make up the national revenue, must be considered in political economy in two ways. They must be considered in their relations to individuals as values and in their relations to the nation as goods. For the revenue of a nation is not appreciated like that of an individual, by its value, but by its utility or by the wants which it can satisfy." (*Considerations sur le revenu national*, .)

In the first place, it is a false abstraction to regard a nation, whose mode of production is based upon value and otherwise capitalistically organized,

as an aggregate body working merely for the satisfaction of the national wants.

In the second place, after the abolition of the capitalist mode of production, but with social production still in vogue, the determination of value continues to prevail in such a way that the regulation of the labor time and the distribution of the social labor among the various groups of production, also the keeping of accounts in connection with this, become more essential than ever

CHAPTER L. THE SEMBLANCE OF COMPETITION.

WE have shown, that the value of commodities, or the price of production regulated by their total value, resolves itself into:

One portion of value replacing constant capital, or representing past labor, used up in the form of means of production in the making of the commodity. This, in brief, is the value, or price, which these means of production carried into the process of production of the commodities. We never speak of individual commodities in this case, but of commodity-capital, that is, of that form, in which the product of capital during a certain period of time, say of one year, presents itself, and of which the individual commodity forms one element, which, moreover, so far as its value is concerned, resolves itself into the same analogous constituents.

One portion of value representing variable capital, which measures the income of the laborer and converts itself into wages for him. The laborer has produced these wages in this variable portion of value. This, briefly, is that portion of value, which represents the paid portion of the new labor added to the above constant portion in the production of commodities.

Surplus-Value, which is that portion of the value of the produced commodities, in which the unpaid, or surplus labor is incorporated. This last portion of the value in its turn assumes the independent forms, which are at the same time forms of revenue, namely the forms of profit on capital (interest on capital as such and profit of enterprise on capital in productive work) and ground-rent, which is claimed by the owner of the land participating in the process of production. The parts mentioned under 2) and 3), that is, that portion of value, which always assumes the revenue forms of wages (but only after having first gone through the form of variable capital), profit and rent, is distinguished from the constant portion mentioned under 1) by the fact that in it that entire portion of value is dissolved, in which the additional labor added to that constant part, to the means of production of the commodities, is materialized. Now, if we leave

aside the constant portion, then it is correct to say that the value of a commodity, to the extent that it represents newly added labor, continually resolves itself into three parts, which form three forms of revenue, namely wages, profit and rent,¹⁵¹ in which the respective magnitudes of value, that is the aliquot portions, which they constitute in the total value, are determined by various peculiar laws, which we have analysed previously. But on the other hand, it would be a mistake to say that the value of wages, the rate of profit, and the rate of rent form independent constituent elements of value, whose composition gives rise to the value of commodities, leaving aside the constant part; in other words, it would be a mistake to say that they are constituent elements of the value of commodities, or of the price of production.¹⁵²

The difference is easily seen.

Take it that the value of the product of a capital of 500 is equal to $400 c + 100 v + 150 s = 650$; let the 150 s be divided into 75 profit + 75 rent. We will also assume, in order to forestall useless difficulties, that this is a capital of average composition, so that its price of production and its value coincide; this coincidence always takes place, whenever the product of such an individual capital may be considered as the product of some portion of the total capital corresponding to the same magnitude.

Here the wages, measured by the variable capital, form 20% of the advanced capital; the surplus-value, calculated on the total capital, forms 30%, namely 15% profit and 15% rent. The entire portion of value of the commodity representing the newly added labor is equal to $100 v + 150 s = 250$. Its magnitude does not depend upon its division into wages, profit and rent. We see by the proportion of these parts to each other that a labor-power, which is paid with 100 in money, say 100 pounds sterling, has supplied a quantity of labor represented by money to the amount of 250 pounds sterling. We see from this that the laborer performed one and a half times as much surplus labor as he did labor for himself. If the working day contained 10 hours, then he worked 4 hours for himself and 6 hours for the capitalist. Therefore the labor of the laborers paid with 100 pounds sterling is expressed in money to the amount of 250 pounds sterling. Outside of this value of 250 pounds sterling there is nothing to divide between laborer and

capitalist, between capitalist and landlord. It is the total value newly added to the value of 400, which is the value of the means of production. The value of 250 thus produced and determined by the quantity of labor materialized by it in the commodities forms the limit of the dividend, which the laborer, the capitalist and the landlord will be able to draw out of this value in the shape of the revenues, wages, profit and rent.

Take it that a capital of the same organic composition, that is, of the same proportion between the employed living labor-power and the constant capital set in motion by it, should be compelled to pay 150 pounds sterling instead of 100 pounds sterling for the same labor-power which sets in motion the constant capital of 400. And let us further assume that profit and rent should share the surplus-value in a different proportion. As we have assumed that the variable capital of 150 pounds sterling sets the same quantity of labor in motion as the variable capital of 100 did, the newly added value would be 250 as before, and the total value of the product would be 650, also as before. But the formula would then read: $400 c + 150 v + 100 s$, and these 100 s would be divided, say, into 45 profit and 55 rent. The proportion, in which the newly produced total value would now be divided among wages, profit and rent, would now be very different. The magnitude of the advanced total capital would also be very different, although it would set only the same total quantity of labor in motion. The wages would amount to $27 \frac{8}{11}\%$, the profit to $8 \frac{2}{11}\%$, and the rent to 10% of the advanced capital. The total surplus-value would, therefore, amount to a little over 18%.

In consequence of the raise in wages the unpaid portion of the total labor would be changed and with it the surplus-value. If the working day contained 10 hours, the laborer would work 6 hours for himself and 4 hours for the capitalist. The proportion of profit and rent would also be changed, the reduced surplus-value would be divided in a different proportion between the capitalist and the landlord. Finally, since the value of the constant capital would have remained the same, while the value of the advanced variable capital would have risen, the reduced surplus-value would express itself in a still more reduced rate of gross profit, by which we mean here the proportion between the total surplus-value and the advanced total capital.

The change in the value of wages, in the rate of profit, and in the rate of rent, whatever might be the effect of the laws regulating the proportion of these parts, could move only within the limits set by the newly produced value of commodities amounting to 250. An exception could take place only, if rent should rest upon a monopoly price. This would not alter the law itself, but merely complicate its analysis. For if we consider only the product itself in this case, then merely the division of the surplus-value would be different. But if we consider its relative value as compared to other commodities, then we should find no other difference but that a portion of the surplus-value had been transferred from them to this particular commodity.

Let us sum up:

lf0445-03-0996-t0001.gif

In the first place, the surplus-value falls by one-third from its former figure, it falls from 150 to 100. The rate of profit falls by a little more than one-third, from 30% to 18%, because the reduced surplus-value must be calculated on an increased advance of total capital. But it does not fall in the same proportion as the rate of surplus-value. This last falls from 150/100 to 100/150, that is, from 150% to 66 2/3%, whereas the rate of profit falls only from 150/500 to 100/550 or from 30% to 18 2/11%. The rate of profit, then, falls proportionately more than the mass of surplus-value, but less than the rate of surplus-value. We find, furthermore, that the values as well as the masses of products remain the same, so long as the same quantity of labor is employed, although the advanced capital has increased by the augmentation of its variable portion. This increase of the advanced capital would indeed make itself felt for a capitalist who would start out in business. But looking upon reproduction as a whole, the augmentation of the variable capital means merely that a larger portion of the new value added by newly performed labor is converted into wages, and thus at first into variable capital instead of into surplus-value and surplus products. The value of the product thus remains the same, because it is bounded on the one hand by the value of the constant capital, 400, and on the other hand by the figure 250, in which the newly added labor is represented. Both of these values remain unaltered. The product would represent the same amount of

use-value in the same quantity of exchange-value, to the extent that it would return into the constant capital, so that the same mass of elements of constant capital would retain the same value. The matter would be different, if the wages should rise, not because the laborer would receive a larger share of his own labor, but if he should receive a larger portion of his own labor, because the productivity of labor would have decreased. In this case, the total value, in which this same labor, paid and unpaid, would be incorporated, would remain the same. But the mass of products, in which this quantity of labor would be incorporated, would be the same, so that the price of each aliquot portion of this product would rise, because each portion would contain more labor. The increased wages of 150 would not represent any more labor than the wages of 100 did before; the reduced surplus-value of 100 would represent merely two-thirds of the product which it did previously, only $66\frac{2}{3}\%$ of the mass of use-values, which were formerly represented by 100. In this case the constant capital would also become dearer to the extent that this product would go back into it. But this would not be the result of the increase in wages. This increase in wages would rather be a result of the increase in the price of commodities and a result of the diminished productivity of the same quantity of labor. Here the impression is given that the raise in wages made the product dearer; however, this raise is not the cause, but rather a result of a change in the value of the commodities, due to the decreased productivity of labor.

On the other hand, so long as all other circumstances remain the same, so long as the same quantity of employed labor is represented by 250, and the value of the means of production handled by it should then rise or fall, then the value of the same quantity of products would rise or fall by the same magnitude. $450\ c + 100\ v + 150\ s$ make the value of the product equal to 700. But $350\ c + 100\ v + 150\ s$ would make the value of the same quantity of products only equal to 600, as against a former 650. Hence, if the advanced capital should increase or decrease, while it sets the same quantity of labor in motion, the value of its product would rise or fall, other circumstances remaining the same, if the increase or decrease of the advanced capital is due to a change in the value of the constant portion of capital. On the other hand, the value of the product remains unchanged, if the increase or decrease of the advanced capital is caused by a change in the value of the variable portion of capital, provided that the productivity of

labor remains the same. In the case of the constant capital, the increase or decrease of its value is not balanced by any opposite movement. But in the case of the variable capital, so long as the productivity of labor remains the same, an increase or decrease of its value is balanced by the opposite movement on the part of the surplus-value, so that the value of the variable capital plus the surplus-value, that is, the new value added by new labor to the means of production and newly incorporated in the product, remains the same.

But if the increase or decrease of the value of the variable capital is due to a rise or fall in the price of commodities, that is, to an increase or decrease of the productivity of the labor employed by this investment of capital, then the value of the product is affected. Only, the rise or fall of wages in this case is not a cause, but an effect.

On the other hand, if the constant capital in the above illustration should remain at 400 c, and if the change from $100 v + 150 s$ to $150 v + 100 s$, that is, an increase of the variable capital, should be due to a decrease in the productivity of labor, not in this same particular line of industry, say in cotton spinning, but perhaps in agriculture, so that it would be a result of a rise in the price of foodstuffs, then the value of the product would remain unchanged. The value of 650 would still be represented by the same quantity of cotton yarn.

The foregoing leads furthermore to the following conclusions: If a decrease in the expenditure of constant capital is due to economies, etc., in such lines of production as supply agriculture with their products, then this, like a direct improvement in the productivity of the employed labor itself, may lead to a reduction of wages, because it would lead to a cheapening of the subsistence of the laborer, and this would imply an increase of the surplus-value; so that the rate of profit in this case would grow for two reasons, namely on the one hand, because the value of the constant capital would decrease, and on the other hand, because the surplusvalue would increase. In our analysis of the conversion of surplus-value into profit we assumed that the wages would not fall, but remain constant, because there we had to investigate the fluctuations of the rate of profit, independent of the changes in the rate of surplus-value. Moreover, the laws which we

developed in that case are general ones, and apply also to investments of capital, the products of which do not pass over into the consumption of the laborer, and in that case changes in the value of the product are without influence upon the wages.

We know, then, that the separation and distribution of the new value added by new labor annually to the means of production, or to the constant part of capital, among the various forms of revenue, namely wages, profit and rent, do not alter the limits of this value itself, do not alter the sum of value to be so distributed; neither can a change in the proportions of these different parts alter their sum, which makes up this given magnitude of value. A given figure of 100 always remains the same, whether it is divided into $50 + 50$, or into $20 + 70 + 10$, or into $40 + 30 + 30$. That portion of the value of the product, which is divided into these revenues, is determined, like the constant portion of the value of capital, by the value of commodities, that is, by the quantity of the labor incorporated in them from case to case. In the first place, then, the quantity of value of the commodities to be distributed among wages, profit and rent is given; in other words, the absolute limit of the sum of the portions of value of these commodities. In the second place, as concerns the individual categories themselves, their average and regulating limits are likewise given. The wages form the basis in this limitation. The wages are regulated on the one side by a natural law; their minimum is determined by the physical minimum required by the laborer for the conservation of his labor-power and for its reproduction; this means a minimum quantity of commodities. The value of these commodities is determined by the labor time required for their reproduction; it is determined by that portion of the new labor added to the means of production, or by that portion of each working day, which the laborer must have for the production and reproduction of an equivalent for the value of these necessary means of subsistence. For instance, if his average daily food requirements have the value of six hours of average labor, then he must work on an average six hours per day for himself. The actual value of his laborpower differs from this physical minimum; it differs according to climate and condition of social development; it depends not merely upon the physical, but also upon the historically developed social needs, which become second nature. But in every country and at any given period this regulating average wage is a given magnitude. The value of all

other revenues thus has its limit. It is always equal to the value, in which the total working day (which coincides in the present case with the average working day, since it comprises the total quantity of labor set in motion by the total social capital) is incorporated, minus that portion of this working day, which is incorporated in wages. Its limit is therefore determined by the limit of that value, in which the unpaid labor is expressed, that is, by the quantity of this unpaid labor. While that portion of the working day, which is required by the laborer for the reproduction of the value of his wages, finds its ultimate limit in the physical minimum of wages, the other portion of the working day, in which surplus labor is incorporated, and with it that portion of value which stands for surplus-value, finds its limit in the physical maximum of the working day, that is, in the total quantity of daily labor time, during which the laborer can be active altogether and still preserve and reproduce his labor-power. As we are here concerned in the distribution of that value, which represents the total labor newly added per year, the working day may here be regarded as a constant magnitude, and is taken for granted as such, no matter how much or how little it may differ from its physical maximum. The absolute limit of that portion of value, which forms surplus-value, and which resolves itself into profit and ground-rent, is thus given. It is determined by the excess of the unpaid portion of the working day over its paid portion, which means by that portion of the value of the total product, in which this surplus labor is realized. If we call the surplus-value thus limited and calculated on the advanced total capital the profit, as I have done, then this profit, so far as its absolute magnitude is concerned, is equal to the surplus-value and, therefore, determined in its boundaries by the same laws as it. On the other hand, the level of the rate of profit is likewise a magnitude inclosed within certain limits by the value of commodities. This rate is the proportion of the total surplus-value to the total social capital advanced in production. If this capital is equal to 500 (say millions) and the surplus-value equal to 100, then 20% form the absolute limit of the rate of profit. The distribution of the social profit at this rate among the various capitals invested in the different spheres of production creates prices of production, which swerve from the values of commodities, and these prices of production are the real regulating average market prices. But this deviation of prices of production from values abolishes neither the determination of prices by values nor the lawful limits of profit. Instead of the value of a commodity being equal to the capital

consumed in it plus the surplus-value contained in it, its price of production is then equal to the capital, k , consumed in it plus the surplus-value falling to its share as a result of the average rate of profit, for instance 20% of the capital advanced in its production, counting both the consumed and the merely employed capital. But this addition of 20% is itself determined by the surplus-value created by the total social capital, and by its proportion to the value of this capital; and for this reason it is 20% and not 10% or 100%. The transformation of the values into prices of production, then, does not abolish the limits of profit, but merely alters its distribution among the various particular capitals, which make up the total social capital, distributes it uniformly among them in the proportion in which they form parts of the value of this total capital. The market prices fall below or rise above these regulating prices of production, but these fluctuations balance each other. If one studies price lists during a certain long period, and if one subtracts the cases, in which the real value of commodities is altered by a change in the productivity of labor, and likewise the cases, in which the process of production has been previously disturbed by natural or social accidents, one will be surprised, in the first place, by the relatively narrow limits of the fluctuations, and, in the second place, by the regularity of their mutual compensation. The same domination of the regulating averages will be found here, which Quételet pointed out in the case of social phenomena. If the equalization of the values of commodities into prices of production does not meet any obstacles, then the rent resolves itself into differential rent, that is, it is limited to the equalization of the surplus-profits, which would be given to some of the capitalists by the regulating prices of production, but which are then appropriated by the landlords. Here, then, the rent has its definite limit of value in the fluctuations of the individual rates of profit, which are caused by the regulation of the prices of production through the general rate of profit. If private ownership of land places obstacles in the way of the equalization of the values of commodities into prices of production, and appropriates absolute rent, then this absolute rent is limited by the excess of the value of the products of the soil over their prices of production, that is, by the excess of the surplus-value in them over the rate of profit assigned to the capitals by the average rate of profit. This difference then forms the limit of the rent, which is always but a certain portion of surplus-value produced and existing in the commodities.

Finally, if the equalization of the surplus-value into average profit meets with obstacles in the various spheres of production in the shape of artificial or natural monopolies, particularly of monopoly in land, so that a monopoly price would be possible, which would rise above the price of production and above the value of the commodities affected by such a monopoly, still the limits imposed by the value of commodities would not be abolished thereby. The monopoly price of certain commodities would merely transfer a portion of the profit of the other producers of commodities to the commodities with a monopoly price. A local disturbance in the distribution of the surplus-value among the various spheres of production would take place indirectly, but they would leave the boundaries of the surplus-value itself unaltered. If a commodity with a monopoly price should enter into the necessary consumption of the laborer, it would increase the wages and thereby reduce the surplus-value, if the laborer would receive the value of his labor-power, the same as before. But such a commodity might also depress wages below the value of labor-power, of course only to the extent that wages would be higher than the physical minimum of subsistence. In this case the monopoly price would be paid by a deduction from the real wages (that is, from the quantity of use-values received by the laborer for the same quantity of labor) and from the profit of the other capitalists. The limits, within which the monopoly price would affect the normal regulation of the prices of commodities, would be accurately fixed and could be closely calculated.

Just as the division of the newly added value of commodities into necessary and surplus labor, wages and surplus-value, and its general division between revenues, finds its given and regulating limits, so the division of the surplus-value itself into profit and ground-rent finds its limit in the laws regulating the equalization of the rate of profit. In the division into interest and profits of enterprise the average profit itself forms the limit for both of them. It furnishes the given magnitude of value, which they may divide among themselves and which is the only one that they can so divide. The definite proportion of this division is here accidental, that is, it is determined exclusively by conditions of competition. Whereas in other cases the balancing of supply and demand implies the cessation of the deviation of market prices from their regulating average prices, that is, the cessation of the influence of competition, it is here the only determinant.

But why? Because the same factor in production, the capital, has to divide its share of the surplus-value between two owners of the same factor in production. But the fact that no definite, lawful, limit for the division of the average profit is found, does not do away with its limit as a part of the value of commodities, any more than the fact that two partners in a certain business, being under the influence of different circumstances, divide their profit unequally, affects the limits of this profit in any way.

Hence, although that portion of the value of commodities, in which the value of the new labor added to the means of production is incorporated, is divided into different parts, which assume independent forms as revenues, this is no reason why wages, profit and ground-rent should be considered as constituting elements, whose addition, or sum, would be the source of the regulating price of commodities (natural price, *prix nécessaire*); it is no reason to think that not the value of commodities, after the subtraction of the constant portion of value, is the original unit separated into these three parts, but rather the price of each one of these three parts is independently determined, and that the price of commodities is then formed by an addition of these three independent magnitudes. In reality the value of commodities is the magnitude which exists first, and it comprises the sum of the total values of wages, profit and rent, whatever may be their relative magnitudes. In the wrong conception, wages, profit and rent are three independent magnitudes of value, whose total magnitude is supposed to produce the magnitude of the value of a commodity, to limit and to determine it.

In the first place it is evident that, if wages, profit and rent constitute the price of commodities, this would apply as much to the constant portion of the value of commodities as to the other portion, in which variable capital and surplus-value are incorporated. This constant portion may here be left entirely out of consideration, since the value of the commodities of which it is made up would likewise resolve itself into wages, profit and rent. We have already shown that this conception denies the existence of such a constant portion of value.

It is furthermore evident that all meaning of value is here eliminated. Only the conception of price remains, in the sense that a certain amount of money is paid to the owners of labor-power, capital and land. But what is

money? Money is not a thing, but a definite form of value, hence it is again conditioned upon value. Let us say, then, that a definite amount of gold or silver is paid for those elements of production, or that they are equalled in our minds to this amount. But gold and silver (and the enlightened economist is proud of this understanding) are themselves commodities, like all others. The price of gold and silver is therefore likewise determined by wages, profit and rent. Hence we cannot determine what wages, profit and rent are, by making them equal to a certain amount of gold or silver, for the value of this gold and silver, by which they are supposed to be estimated as equivalents, is precisely supposed to be determined by them, independently of gold and silver, that is, independently of the value of any commodity, for this value is supposed to be the product of those three. To say that the value of wages, profit and rent consist in their being equivalent to a certain quantity of gold and silver, would merely be the same as saying that they are equal to a certain quantity of wages, profit and rent.

Take wages first. For it is necessary to make labor the point of departure, even in this view of the matter. How, then, is the regulating price of wages determined, the price around which its market prices oscillate?

Let us reply that it is determined by the demand and supply of labor-power. But what sort of a demand is this? It is a demand made by capital. The demand for labor is therefore at the same time a supply of capital. In order to speak of a supply of capital, we should know above all what capital is. What is capital made of? If we select its simplest forms, it consists of money and commodities. But money is merely a form of commodities. Capital, then, consists of commodities. But the value of commodities, according to our assumption, is first determined by the price of the labor producing them, by wages. The existence of wages is here a prerequisite and is considered as a constituting element of the price of commodities. Now this price is to be determined by the proportion of the supplied labor to capital. The price of the capital itself is equal to the price of the commodities of which it is composed. The demand of capital for labor is equal to the supply of capital. And the supply of capital is equal to the supply of a quantity of commodities of a given price, and this price is regulated in the first place by the price of labor, and the price of labor in its turn is equal to that portion of the price of commodities, which makes up

the variable capital, which is transferred to the laborer in exchange for his labor; and the price of the commodities, of which this variable capital is composed, is in its turn primarily determined by the price of labor; for it is determined by the prices of wages, profit and rent. In order to determine wages, we cannot, therefore, assume the previous existence of capital, for the value of the capital is itself determined in part by wages.

Besides, the dragging of competition into this problem does not help any. Competition makes the market prices of labor rise and fall. But suppose that the demand and supply of labor are balanced. What determines wages in that case? Competition. But we have just assumed that competition ceases to act as a determinant, that it abolishes its effects by the equilibrium of its two opposing forces. We are precisely trying to find the natural price of wages, that is, the price of labor not regulated by competition, but which, on the contrary, regulates it.

Nothing remains but to determine the necessary price of labor by the necessary subsistence of the laborer. But these articles of food are commodities, which have a price. The price of labor is therefore determined by the price of the necessary means of existence, and the price of the means of existence, like that of all other commodities, is determined primarily by the price of labor. Therefore the price of labor determined by the price of the means of existence is determined by the price of labor. The price of labor is determined by itself. In other words, we do not know by what the price of labor is determined. Labor in this case has any price at all, because it is considered as a commodity. In order, therefore, to speak of the price of labor, we must know what price itself means. But what price itself is, we do not learn in this way at all.

But let us assume, that the necessary price of labor had been determined in this agreeable manner. Then how is the average profit determined, the profit of every capital in normal conditions, which forms the second element of the price of commodities? The average profit must be determined by an average rate of profit; how is this rate determined? By the competition between the capitalists? But this competition itself is conditioned upon the existence of profit. It presupposes the existence of different rates of profit, and thus of different profits, either in the same, or in

different spheres of production. Competition can influence the rate of profit only to the extent that it affects the prices of commodities. Competition can merely make the producers within the same sphere of production sell their commodities at the same prices, and make them sell their commodities in different spheres of production at prices which will give them the same profit, will give them the same proportional addition to the price of commodities, which has already been partially determined by wages. Hence competition cannot balance anything but inequalities in the rate of profit. In order to balance unequal rates of profit, the profit as an element in the price of commodities must already exist. Competition does not create it. It lowers or raises its level, but it does not create this level, which appears whenever the balance has been struck. And when we speak of a necessary rate of profit, we wish precisely to know the rate of profit which is independent of the movements of competition, and which rather regulates these movements. The average rate of profit appears, when the forces of the competing capitalists balance each other. Competition may bring about this balance, but cannot create the rate of profit which appears whenever this balance is found. As soon as the equilibrium is reached, why is the rate of profit 10, or 20, or 100%? On account of competition? No, on the contrary, competition has done away with the causes, which produced deviations from the rate of 10, or 20, or 100%. It has brought about a price of commodities, by which every capital yields the same profit in proportion to its magnitude. The magnitude of this profit itself is independent of it. It merely reduces all deviations to this magnitude. One man competes with another, and competition compels him to sell his commodities at the same price as the other. But why is this price 10 or 20 or 100%?

Nothing remains under these circumstances but to declare that the rate of profit, and with it the profit itself arises in some unaccountable manner by a certain addition to the price of commodities, which to that extent was determined by the wages. The only thing which competition tells us is that this rate of profit must have a certain figure. But we knew that before, when we spoke of an average rate of profit and of a “necessary price” of profit.

It is quite unnecessary to thrash this absurd process over in the case of ground-rent. It is evident, even so, that it, logically pursued, makes profit and rent appear as additions made by unaccountable laws to the price of

commodities, which is primarily determined by wages. In short, competition has to shoulder the duty of explaining all inexplicable ideas of the economists, whereas the economists should rather explain competition.

Now, if we leave aside the illusion of a profit and rent created by the circulation, that is of parts of price arising through sale — for circulation can never give what it did not first receive — the matter simply amounts to this:

Let the price of a commodity determined by wages be 100; let the rate of profit be 10% of the wages, and the rent 15% of the wages. Then the price of the commodity determined by wages, profit and rent is 125. These added 25 cannot come from the sale of this commodity. For all sellers sell to each other at 125 what has actually cost only 100 in wages, and the result is the same as though they had all sold at 100. The operation must rather be studied independently of the process of circulation.

If the three revenues share the commodity itself, which now costs 125 — and it does not alter the matter, if the capitalist should first sell at 125, then pay 100 to the laborer, 10 to himself, and 15 to the landlord — then the laborer receives $\frac{4}{5}$, equal to 100, of the value and of the product. The capitalist receives $\frac{2}{25}$ of the value and of the product, and the landlord $\frac{3}{25}$. When the capitalist sells at 125, instead of at 100, he merely gives to the laborer $\frac{4}{5}$ of the product, in which his labor is incorporated. This would be the same, if he had given 80 to the laborer and kept back 20, of which he would share 8 and the landlord 12. In this case he would have sold the commodity at its value, since in fact the additions to the price of the commodity are made independently of the value of the commodity, which is assumed to be determined here by the value of labor-power. This amounts in a roundabout way to saying that in this conception the term wages, here 100, is equal to the value of the product, that is, equal to that sum of money, in which the same definite quantity of labor is represented; but that this value again differs from the real wages and therefore leaves a surplus. Only, in the present case, this is obtained nominally by an addition to the price. Hence, if the wages were 110 instead of 100, the profit would have to be 11 and the ground-rent $16\frac{1}{2}$, so that the price of the commodity would be $137\frac{1}{2}$. This would leave the proportion unaltered. But as the division would

always be obtained by a nominal addition of definite percentages to the wages, the price would rise and fall with the wages. The wages are here first assumed as equal to the value of the commodity, and then again separated from it. In fact, however, the matter amounts in a roundabout and meaningless way to this, that the value of the commodity is determined by the quantity of labor contained in it, whereas the value of wages is determined by the price of the necessities of life, and the surplus of value above the wages forms profit and rent.

The separation of the value of commodities, after the subtraction of the value of the means of production consumed in their creation, this separation of this given quantity of value determined by the quantity of labor incorporated in the produced commodities into three parts, namely into wages, profit and rent, which assume the shape of independent and mutually unrelated revenues, this same separation appears on the surface of capitalist production, and consequently in the minds of the agents bounded by it, in an inverted form.

Let the total value of a certain commodity be 300, of which 200 may be the value of the means of production, or elements of constant capital, consumed in its production. This leaves 100 as the amount of the new value added to this commodity in its process of production. This new value of 100 is all that is available for division among these three forms of revenue. Let us place the figure for wages at x , for profit at y , for ground-rent at z , then the sum of $x + y + z$ will always be 100 in our present case. In the conception of the industrials, merchants and bankers, as in that of the vulgar economists, matters are supposed to pass in an entirely different way. According to them it is not the value of the commodity, which equals 100 after subtracting the value of the means of production consumed in it, nor is it this 100 which is divided into x , y and z . According to them it is rather the price of the commodity, which is composed of wages, profit and rent, whose figures of value are determined independently of the value of this commodity and independently of each other, so that x , y and z exist independently, each by itself and is so determined, while the sum of these magnitudes, which may be larger or smaller than 100, makes up the value of the commodity by adding these three different values together. This case of mistaken identity is necessary:

Because the component parts of value in the commodities face each other as independent revenues, which are referred back as such to three very dissimilar agencies in production, namely to labor, capital and land, and which then seem to arise out of these. The ownership of labor-power, of capital, of land, is the cause, which assigns these different parts of the value of commodities to these respective owners, and transforms these parts into revenue for them. But the value does not arise from a transformation of its parts into revenue, it must rather exist before it can be converted into revenue, before it can assume this form. The appearance of the reverse must fortify itself so much the more, as the determination of the relative magnitude of these three parts follows different laws, whose connection with and limitation by the value of commodities themselves does not show itself on the surface by any means.

We have seen that a general rise or fall of wages, by causing a movement in the opposite direction on the part of the average rate of profit, so long as other circumstances remain the same, changes the prices of production of the different commodities, raises some and lowers others, according to the average composition of the capital in the respective spheres of production. There is no doubt that at least in some spheres of production the experience is made, that the average price of a commodity rises, because wages have risen, and falls, because wages have fallen. What is not “experienced” is the secret regulation of this change by the value of commodities, which is independent of wages. But if the rise of wages is local, if it takes place only in particular spheres of production in consequence of peculiar circumstances, then a corresponding nominal raise of prices may occur in the case of these commodities. The rise of the relative value of one kind of commodities as against others, which have been produced with an unchanged scale of wages, is then merely a reaction against the local disturbance of a uniform distribution of surplus-value among the various spheres of production, a means of leveling particular rates of profit into an average rate. The “experience,” which is met in that case, is once more the determination of the price by the wages. In both these cases, the same experience shows that the wages determine the prices of commodities. What is not “experienced,” is the hidden cause of this interrelation. Furthermore: The average price of labor, that is, the value of labor-power, is

determined by the price of production of the necessary articles of subsistence. If the price of these falls, so does that of those. What is once more experienced here, is the existence of a connection between wages and the price of commodities. But the cause may seem to be an effect, and the effect a cause, as is also the case in the movements of market prices, where a rise of wages above its average corresponds to the rise of the market prices above the prices of production during periods of prosperity, and subsequent fall of wages below their average corresponds to a fall of market prices below the prices of production. Owing to the dependence of prices of production upon the values of commodities, the primary experience, aside from the oscillating movements of the market prices, should always be that the rate of profit falls whenever wages rise, and vice versa. But we have seen that the rate of profit may be determined by the movements of the value of constant capital, independently of the movements of wages; so that wages and the rate of profit, instead of moving in opposite directions, move in the same direction, and may rise or fall together. If the rate of surplus-value were directly identical with the rate of profit, then this could not happen. Even if wages should rise as a result of a rise in the prices of foodstuffs, the rate of profit may remain the same, or may even rise, owing to a greater intensity of labor or a prolongation of the working day. All these experiences corroborate the illusion created by the apparently independent and reversed form of the parts of value, as though either the wages alone, or wages and profit together determined the value of commodities. As soon as this seems to be the case with reference to wages, so that the price of labor and the value created by labor seem to coincide, the same applies as a matter of course to profit and rent. Their prices, that is, their expression in money, must then seem to be regulated independently of labor and of the value produced by it.

Let us assume that the values of commodities, or the apparently independent prices of production, coincide seemingly directly and continually with the market prices of commodities, instead of merely enforcing themselves as the regulating average prices by the continual balancing of the fluctuations of market prices. Let us assume, furthermore, that reproduction always takes place under the same unaltered conditions, so that the productivity of labor remains constant in all elements of capital. Finally, let us assume that that portion of the value of the produced

commodities, which is formed in every sphere of production by the addition of a new quantity of labor, or by the addition of a newly produced value to the value of the means of production, is always divided according to the same unaltered proportion into wages, profit and rent, so that the actually paid wages, the actually realized profit, and the actual rent always directly coincides with the value of labor-power, with that portion of the total surplus-value which falls to the share of every active part of total capital by means of the average rate of profit, and with the limits, in which ground-rent is normally held upon this basis. In one word, let us assume that the division of the produced social values and the regulation of the prices of production takes place on a capitalist basis, but that competition is abolished.

Under these assumptions, then, under which the value of commodities would be constant and would appear so, under which that part of the value of commodities which resolves itself into revenues would remain a constant magnitude and would always present itself as such, and under which, finally, this given and constant part of value would always be divided according to constant proportions into wages, profit and rent, even under these assumptions would the real movement necessarily appear in an inverted form: not as a division of a previously given quantity of value into three parts, which assume mutually independent forms of revenue, but on the contrary, as the formation of this quantity of value by the sum of the independent and selfdetermined elements of wages, profit and rent, of which it is composed. This illusion would necessarily arise, because in the actual movement of the individual capitals and of the commodities produced by them not the value of the commodities would seem to precede their division, but vice versa, the parts into which it is divided would seem to exist before the value of the commodities. In the first place we have seen that to every capitalist the cost price of his commodities appears as a given magnitude and continually presents itself as such in the actual price of production. But the cost price is equal to the value of the constant capital, the advanced means of production, plus the value of labor-power, which, however, presents itself to the agent in production in the irrational shape of a price of labor, so that the wages appear at the same time as a revenue for the laborer. The average price of labor is a given magnitude, because the value of labor-power, like that of any other commodity, is determined by the

labor time required for its reproduction. But as concerns that portion of the value of commodities, which resolves itself into wages, it does not arise from the fact that it assumes this form of wages, nor from the fact that the capitalist advances to the laborer his share of his own product in the shape of wages, but from the fact that the laborer produces an equivalent for his wages, that is, that a portion of his daily or annual labor produces the value contained in the price of his labor-power. But the wages are stipulated by contract, before the value equivalent to them has been produced. As an element of price, whose magnitude is given before the commodity and its value have been produced, as a constituent part of the cost price, wages do not appear as a part which detaches itself in an independent form from the total value of the commodity, but rather as a given magnitude, which predetermines this value, a creator of price or value. A role similar to that of wages in the cost price of commodities is played by the average profit in their price of production, for the price of production is equal to the cost price plus the average profit on the advanced capital. This average profit figures practically, in the conception and in the calculation of the capitalist himself, as a regulating element, not merely to the extent that it determines the transfer of the capitals from one sphere of investment into another, but also in all sales and contracts, which embrace a process of reproduction extending over long epochs. But whenever it figures in this way, it is a previously existing magnitude, which is in fact independent of the value and surplus-value produced in any particular sphere of production, and still more independent of the value and surplus-value produced by any individual investment of capital in any sphere of production. It does not present itself as a result of a division of value, but rather as a magnitude independent of the value of the produced commodities, as existing from the start and determining the average price of the commodities, that is, as a creator of value. Indeed, the surplus-value, owing to its separation into various and mutually unrelated parts, appears in a still more concrete form as a prerequisite for the creation of the value of commodities. A part of the average profit, in the form of interest, faces the capitalist independently as an element preceding the production of commodities and of their value. Although the fluctuations of the amount of interest are considerable, yet at any specific moment it is a given magnitude for every capitalist, and it enters into the cost price of the commodities produced by any individual capitalist. So does also the ground-rent in the form of lease money fixed by

contract in the case of the agricultural capitalist, and in the form of rent for business rooms in the case of other business men. These parts, into which surplus-value is divided, being given as elements of cost price for the individual capitalist, appear for this reason inversely as creators of surplus-value; they appear as creators of a portion of the price of commodities, just as wages appear as the creator of the other portion. The secret of the continual reappearance of these divided parts of commodity value in the role of prerequisites for the formation of value itself is simply this, that the capitalist mode of production, like any other, does not merely always reproduce the material product, but also the economic conditions, the definite economic forms of its creation. Its result, therefore, appears as continually as its prerequisites, as its prerequisites appear in the role of its results. And it is this continual reproduction of the same conditions, which the individual capital anticipates in a matter of fact way as an indubitable fact. So long as the capitalist mode of production persists as such, a portion of the newly added labor resolves itself continually into wages, another into profit (interest and profit of enterprise), and a third into rent. In the contracts between the owners of the various agencies of production this is always assumed, and this assumption is correct, no matter how much the relative proportions may fluctuate in individual cases. The definite shape, in which the parts of value face each other, is assumed as pre-existing, because it is continually reproduced, and it is continually reproduced, because it is continually taken for granted.

It is true, that both experience and the appearance of things demonstrate the fact that the market prices, whose influence seems to the capitalist to be indeed the whole thing in the determination of values, are by no means dependent upon these anticipations, so far as their amount is concerned. They are not governed by any contracts demanding a high or a low rent and interest. But the market prices are constant only in their changes, and their average for a certain long period results in the respective averages of wages, profit and rent as magnitudes dominating the constant ones, such as the market prices, in the last analysis.

On the other hand, it seems like a simple reflection, that if wages, profit and rent are creators of value for the reason that they seem to precede the production of value, and that they are taken for granted by the individual

capitalist in his cost price and price of production, then the constant portion of value, whose value enters as a given quantity into the production of every commodity, is also a creator of value. But the constant portion of value is nothing but a quantity of commodities and, therefore, of values of commodities. Thus we should arrive at the absurd tautology that the value of commodities is the creator and cause of the value of commodities.

If the capitalist were interested in reflecting about this — and his reflections as a capitalist are dictated exclusively by his interests and his interested motives — his experience would show him, that the product, which he himself produces, passes over into other spheres of production as a constant part of capital, and that products of these other spheres of production pass over into his own product as constant parts of capital. Owing to the fact that the additional value of his own new production, from his point of view, seems to be formed by means of wages, profit and rent, the same appearance holds good also in the case of the constant portion consisting of products of other capitalists. And so the price of the constant portion of capital, and with it the total value of the commodities, reduces itself in the last resort, although in a somewhat unaccountable manner, to a sum of values resulting from the addition of the independent creators of value, wages, profit and rent, which are regulated by different laws and come from different sources.

Whether the commodities are sold, or not sold, at their values, whether their value is determined in one way or another, is quite immaterial for the individual capitalist. This determination of values is from the very outset a process passing behind his back and controlled by conditions independent of himself, because it is not the values, but the divergent prices of production, which form the regulating average prices in every sphere of production. The determination of values as such, interests and influences the individual capitalist and the capital in each sphere of production only to the extent that the reduced or increased quantity of labor required in accordance with the rise or fall of the productive power of labor, enables him in one case to make an extra profit, and compels him in another to raise the price of his commodities, because an additional amount of wages, an additional amount of constant capital, and consequently some more interest, fall upon each individual part of the product, or upon the individual

commodities. This determination of values interests him only to the extent that it raises or lowers the cost of production of commodities for himself, in other words, only to the extent that it places him in an exceptional position.

On the other hand, wages, interest and rent appear to him as regulating boundaries, not only of the price at which he can realize the profit of enterprise, that is, the profit falling to his share in his capacity as a producing capitalist, but also of the price at which he must be able to sell his commodities, if he is to keep his reproduction going at all. It is quite immaterial for him, whether he realises the value and surplus-value in his commodities by their sale, provided only that he gets the customary profit or enterprise or more than that, so long as he pockets this surplus over and above the individual cost price determined for him by wages, interest and rent. Aside from the constant portion of capital, wages, interest and rent appear to him, therefore, as the limiting, creating, determining elements of the price of commodities. For instance, if he can succeed in depressing wages below their normal level, below the value of labor-power, if he can obtain capital at a lower rate of interest, if he can pay less than the normal amount for rent, then he does not care, whether he sells his product below its value, or even below its price of production, so that he gives away without any equivalent a portion of the surplus-value contained in the commodities. This applies even to the constant portion of capital. For instance, if an industrial capitalist can buy his raw material below its price of production, then this protects him against loss, even if he sells it in his own finished product under its price of production. His profit of enterprise may remain the same, or may even increase, so long as the excess of the price of commodities over its elements remains the same or increases. But aside from the value of the means of production, which enter into his own production with a given price, it is precisely wages, interest and rent which enter into this production as limiting and regulating amounts of price. Consequently they appear to him as elements determining the price of commodities. The profit of enterprise, from his point of view, seems determined either by the excess of the market prices, dependent upon accidental conditions of competition, over the immanent value of commodities determined by those elements of price. Or, to the extent that this profit itself exerts a determining influence upon market prices, it seems itself dependent upon the competition between buyers and sellers.

In the competition, both of the individual capitalists among themselves and in the competition on the world market, it is the given and presupposed magnitudes of wages, interest and rent which enter into the calculation as constant and regulating magnitudes. They are constant, not in the sense of being unalterable magnitudes, but in the sense that they are given in any individual case and that they form the constant boundary for the continually fluctuating market prices. For instance, in the competition on the world market the question is exclusively as to whether the commodities can be sold at, or below, the existing world market prices with a profit, as to whether, with the existing wages, interest and rent a corresponding profit of enterprise can be realized. If the wages and the price of land are low in a certain country, while the interest on capital is high, because the capitalist mode of production has not been developed in it, whereas in some other country the wage and the price of land are nominally high, while the interest on capital is low, then the capitalist employs in the one country more labor and land, in the other relatively more capital. These factors enter as determining elements into the calculation by which the degree of possible competition between these two countries is estimated. Here, then, experience shows theoretically, and the interested calculation of the capitalist shows practically, that the prices of commodities are determined by wages, interest and rent, by the price of labor, of capital and of land, and that these elements of price are indeed the regulating factors of price.

Of course, this always leaves an element which is not assumed as pre-existing, but which rather results from the market price of commodities, namely the surplus above the cost price formed by the addition of these elements, namely of wages, interest and rent. This fourth element seems to be determined in every individual case by competition, and in the long average of cases by the average profit, which in its turn is regulated by this same competition, only at longer intervals.

On the basis of capitalist competition it becomes so much a matter of course to separate the value, in which the newly added labor is represented, into the forms of revenue known as wages, profit and ground-rent, that this method is applied (not to mention past stages of history, of which we gave illustrations under the head of ground-rent) even in cases, in which the

conditions required for those forms of revenue are missing. In other words, everything is counted under these heads by analogy.

If an independent laborer — for instance, a small farmer, in whose case all three forms of revenue may be used — works for himself and sells his own product, he is, in the first place, considered as his own employer (capitalist), who employs himself as a laborer, and as his own landlord, who employs himself as his own tenant. To himself as a wage worker he pays his wages, to himself as a capitalist he turns over his profit, and to himself as a landlord he pays his rent. Assuming the capitalist mode of production and the conditions corresponding to it to be the general basis of society, this conception is correct, in so far as he does not owe it to his labor, but to his ownership of means of production — which have here assumed the general form of capital — that he is able to appropriate his own surplus labor. And furthermore, to the extent that he creates his own product in the shape of commodities, and thus depends upon its price (and even if he does not depend upon it, this price can be estimated), the quantity of surplus labor, which he can realize, does not depend upon its own size, but upon the general rate of profit; and in like manner any surplus above the amount of surplus-value allowed by the general rate of profit is not determined by the quantity of labor performed by himself, but can be appropriated by him only because he is the owner of the land. Because a form of production not corresponding to the capitalist mode of production may thus be brought in line with its forms of revenue — and to a certain extent not incorrectly — the illusion is strengthened so much the more that the capitalist conditions are the natural conditions of any mode of production.

On the other hand, if we reduce the wages to their general basis, namely to that portion of the product of the producer's own labor which passes over into the individual consumption of the laborer; if we relieve this portion of its capitalist limitations and extend it to that volume of consumption, which is permitted, on the one hand, by the existing productivity of society (that is the social productivity of his own individual labor in its capacity as a truly social one), and on the other hand, required by the full development of his individuality; if we reduce the surplus labor and the surplus product to that measure, which is required under the existing conditions of social production, on the one hand for the formation of an insurance and reserve

fund, and on the other hand for the continuous expansion of reproduction to an extent dictated by social needs; finally, if we include in number one, necessary labor, and number two, surplus labor, that quantity of labor, which must always be performed by the ablebodied for the incapacitated or immature members of society, in other words, if we deprive both wages and surplus-value, both necessary and surplus labor, of their specifically capitalist character, then we have not these forms, but merely their foundations, which are common to all social modes of production.

Moreover, this manner of generalizing was also used in previous modes of production, for instance, in the feudal one. Conditions of production, which did not correspond to it at all, which stood entirely outside of it, were counted in as feudal relations. This was done, for instance, in England, in the case of tenures in common socage (as distinguished from tenures on knight's service), which comprised merely monetary obligations and were feudal in name only.

CHAPTER LI. CONDITIONS OF DISTRIBUTION AND PRODUCTION.

THE new value added by the annual new labor — and thus also that portion of the annual product, in which this value is represented and may be drawn out of the total fund and separated from it — is divided into three parts, which assume three different forms of revenue. These forms indicate that one portion of this value belongs, or goes to, the owner of labor-power, another portion to the owner of capital, and a third portion to the owner of land. These, then are forms, or conditions, of distribution, for they express conditions, under which the newly produced total value is distributed among the owners of the different agencies of production.

To the ordinary mind these conditions of distribution appear as natural conditions, as conditions arising from the nature of all social production, from the laws of human production in general. While it cannot be denied that precapitalist societies show other modes of distribution, yet those modes are interpreted as undeveloped, imperfect, disguised, differently colored modes of these natural conditions of distribution, which have not reached their purest expression and their highest form.

The only correct thing in this conception is this: Assuming some form of social production to exist (for instance, that of the primitive Indian communes, or that of the more artificially developed communism of the Peruvians), a distinction can always be made between that portion of labor, which supplies products directly for the individual consumption of the producers and their families — aside from the part which is productively consumed — and that portion of labor, which produces surplus products, which always serve for the satisfaction of social needs, no matter what may be the mode of distribution of this surplus product, and whoever may perform the function of a representative of these social needs. The identity of the various modes of distribution amounts merely to this, that they are identical, if we leave out of consideration their differences and specific forms and keep in mind only their common features as distinguished from their differences.

A more advanced, more critical mind, however, admits the historically developed character of the condition of distribution,¹⁵³ but clings on the other hand so much more tenaciously to the unaltering character of the conditions of production arising from human nature and thus independent of all historical development.

On the other hand, the scientific analysis of the capitalist mode of production demonstrates that it is a peculiar mode of production, specifically defined by historical development; that it, like any other definite mode of production, is conditioned upon a certain stage of social productivity and upon the historically developed form of the forces of production. This historical prerequisite is itself the historical result and product of a preceding process, from which the new mode of production takes its departure as from its given foundation. The conditions of production corresponding to this specific, historically determined, mode of production have a specific, historical, passing character, and men enter into them as into their process of social life, the process by which they create their social life. The conditions of distribution are essentially identical with these conditions of production, being their reverse side, so that both conditions share the same historical and passing character.

In the study of conditions of distribution, the start is made from the alleged fact, that the annual product is distributed among wages, profit and rent. But if so expressed, it is a misstatement. The product is assigned on one side to capital, on the other to revenues. One of these revenues, wages, never assumes the form of a revenue, a revenue of the laborer, until it has first faced this laborer in the form of capital. The meeting of the produced requirement of labor and of the general products of labor as capital, in opposition to the direct producers, includes from the outset a definite social character of the material requirements of labor as compared to the laborers, and with it a definite relation, into which they enter in production itself with the owners of the means of production and among themselves. The transformation of these means of production into capital implies on their part the expropriation of the direct producers from the soil, and thus a definite form of property in land.

If one portion of the product were not transformed into capital, the other would not assume the form of wages, profit and rent.

On the other hand, just as the capitalist mode of production is conditioned upon this definite social form of the conditions of production, so it reproduces them continually. It produces not merely the material products, but reproduces continually the conditions of production, in which the others are produced, and with them the corresponding conditions of distribution.

It may indeed be said that capital (and the ownership of land implied by it) is itself conditioned upon a certain mode of distribution, namely the expropriation of the laborers from the means of production, the concentration of these conditions in the hands of a minority of individuals, the exclusive ownership of land by other individuals, in short, all those conditions, which have been described in the Part dealing with Primitive Accumulation (Volume I. Chapter XXVI). But this distribution differs considerably from the meaning of “conditions of distribution,” provided we invest them with a historical character in opposition to conditions of production. By the first kind of distribution is meant the various titles to that portion of the product, which goes into individual consumption. By conditions of distribution, on the other hand, we mean the foundations of specific social functions performed within the conditions of production themselves by special agents in opposition to the direct producers. They imbue the conditions of production themselves and their representatives with a specific social quality. They determine the entire character and the entire movement of production.

Capitalist production is marked from the outset by two peculiar traits.

It produces its products as commodities. The fact that it produces commodities does not distinguish it from other modes of production. Its peculiar mark is that the prevailing and determining character of its products is that of being commodities. This implies, in the first place, that the laborer himself acts in the role of a seller of commodities, as a free wage worker, so that wage labor is the typical character of labor. In view of the foregoing analyses it is not necessary to demonstrate again, that the relation

between wage labor and capital determines the entire character of the mode of production. The principal agents of this mode of production itself, the capitalist and the wage worker, are to that extent merely personifications of capital and wage labor. They are definite social characters, assigned to individuals by the process of social production. They are products of these definite social conditions of production.

The character, first of the product as a commodity, secondly of the commodity as a product of capital, implies all conditions of circulation, that is, a definite social process through which the products must pass and in which they assume definite social forms. It also implies definite relations of the agents in production, by which the formation of value in the product and its reconversion, either into means of subsistence or into means of production, is determined. But aside from this, the two above-named characters of the product as commodities, and of commodities as products of capital, dominate the entire determination of value and the regulation of the whole production by value. In this specific form of value, labor appears on the one hand only as social labor; on the other hand, the distribution of this social labor and the mutual supplementing and circulation of matter in the products, the subordination under the social activity and the entrance into it, are left to the accidental and mutually nullifying initiative of the individual capitalists. Since these meet one another only as owners of commodities, and every one seeks to sell his commodity as dearly as possible (being apparently guided in the regulation of his production by his own arbitrary will), the internal law enforces itself merely by means of their competition, by their mutual pressure upon each other, by means of which the various deviations are balanced. Only as an internal law, and from the point of view of the individual agents as a blind law, does the law of value exert its influence here and maintain the social equilibrium of production in the turmoil of its accidental fluctuations.

Furthermore, the existence of commodities, and still more of commodities as products of capital, implies the externalization of the conditions of social production and the personification of the material foundations of production, which characterize the entire capitalist mode of production.

The other specific mark of the capitalist mode of production is the production of surplus-value as the direct aim and determining incentive of production. Capital produces essentially capital, and does so only to the extent that it produces surplus-value. We have seen in our discussion of relative surplus-value, and in the discussion of the transformation of surplus-value into profit, that a mode of production peculiar to the capitalist period is founded upon this. This is a special form in the development of the productive powers of labor, in such a way that these powers appear as self-dependent powers of capital lording it over labor and standing in direct opposition to the laborer's own development. Production which has for its incentive value and surplus-value implies, as we have shown in the course of our analyses, the perpetually effective tendency to reduce the labor necessary for the production of a commodity, in other words, to reduce its value, below the prevailing social average. The effort to reduce the cost price to its minimum becomes the strongest lever for the raising of the social productivity of labor, which, however, appears under these conditions as a continual increase of the productive power of capital.

The authority assumed by the capitalist by his personification of capital in the direct process of production, the social function performed by him in his capacity as a manager and ruler of production, is essentially different from the authority exercised upon the basis of production by means of slaves, serfs, etc.

Upon the basis of capitalist production, the social character of their production impresses itself upon the mass of direct producers as a strictly regulating authority and as a social mechanism of the labor process graduated into a complete hierarchy. This authority is vested in its bearers only as a personification of the requirements of labor standing above the laborer. It is not vested in them in their capacity as political or theoretical rulers, in the way that it used to be under former modes of production. Among the bearers of this authority, on the other hand, the capitalists themselves, complete anarchy reigns, since they face each other only as owners of commodities, while the social interrelations of production manifest themselves to these capitalists only as an overwhelming natural law, which curbs their individual license.

It is only because labor is presumed as wage labor, and the means of production in the form of capital, only on account of this specific social form of these two essential agencies in production, that a part of the value (product) presents itself as surplus-value and this surplus-value as profit (rent), as a gain of the capitalists, as additional available wealth belonging to the capitalist. But only because they present themselves as his profit, do the additional means of production, which are intended for the expansion of reproduction, and which form a part of this profit, present themselves as new additional capital, and only for this reason does the expansion of the process of reproduction present itself as a process of capitalist accumulation.

Although the form of labor, as wage labor, determines the shape of the entire process and the specific mode of production itself, it is not wage labor which determines value. In the determination of value the question turns around social labor time in general, about that quantity of labor, which society in general has at its disposal, and the relative absorption of which by the various products determines, as it were, their respective social weights. The definite form, in which the social labor time enforces itself in the determination of the value of commodities, is indeed connected with the wage form of labor and with the corresponding form of the means of production as capital, inasmuch as the production of commodities becomes the general form of production only upon this basis.

Now let us consider the so-called conditions of distribution themselves. Wages are conditioned upon wage labor, profit upon capital. These definite forms of distribution have for their prerequisites definite social characters on the part of the conditions of production, and definite social relations of the agents in production. The definite condition of distribution, therefore, is merely the expression of the historically determined condition of production.

And now let us take profit. This definite form of surplus-value is a prerequisite for the new creation of means of production by means of capitalist production. It is a relation which dominates reproduction, although it seems to the individual capitalist as though he could consume his entire profit as his revenue. But he meets barriers which hamper him

even in the form of insurance and reserve funds, laws of competition, etc. These demonstrate to him by practice that profit is not a mere category in the distribution of the product for individual consumption. Furthermore, the entire process of capitalist production is regulated by the prices of products. But the regulating prices of production are in their turn regulated by the equalization of the rate of profit and by the distribution of capital among the various social spheres of production in correspondence with this equalization. Profit, then, appears here as the main factor, not of the distribution of products, but of their production itself, as a part in the distribution of capitals and of labor among the various spheres of production. The division of profit into profit of enterprise and interest appears as the distribution of the same revenue. But it arises primarily from the development of capital in its capacity as a self-expanding value, creating surplus-value, it arises from this definite social form of the prevailing process of production. It develops credit and credit institutions out of itself, and with them the shape of production. In interest, etc., the alleged forms of distribution enter as determining elements of production into the price.

Ground-rent might seem to be a mere form of distribution, because private land as such does not perform any, or at least no normal, function in the process of production itself. But the fact that, first, rent is limited to the excess above the average profit, and, secondly, that the landlord is depressed by the ruler and manager of the process of production and of the entire social life's process to the position of a mere holder of land for rent, a usurer in land and collector of rent, is a specific historical result of the capitalist mode of production. The fact that the earth received the form of private property is a historical requirement for this mode of production. The fact that private ownership of land assumes forms, which permit the capitalist mode of production in agriculture, is a product of the specific character of this mode of production. The income of the landlord may be called rent, even under other forms of society. But it differs essentially from the rent as it appears under the capitalist mode of production.

The so-called conditions of distribution, then, correspond to and arise from historically defined and specifically social forms of the process of production and of conditions, into which human beings enter in the process by which they reproduce their lives. The historical character of these

conditions of distribution is the same as that of the conditions of production, one side of which they express. Capitalist distribution differs from those forms of distribution, which arise from other modes of production, and every mode of distribution disappears with the peculiar mode of production, from which it arose and to which it belongs.

The conception, which regards only the conditions of distribution historically, but not the conditions of production, is, on the one hand, merely an idea begotten by the incipient, but still handicapped, critique of bourgeois economy. On the other hand it rests upon a misconception, an identification of the process of social production with the simple labor process, such as might be performed by any abnormally situated human being without any social assistance. To the extent that the labor process is a simple process between man and nature, its simple elements remain the same in all social forms of development. But every definite historical form of this process develops more and more its material foundations and social forms. Whenever a certain maturity is reached, one definite social form is discarded and displaced by a higher one. The time for the coming of such a crisis is announced by the depth and breadth of the contradictions and antagonisms, which separate the conditions of distribution, and with them the definite historical form of the corresponding conditions of production, from the productive forces, the productivity, and development of their agencies. A conflict then arises between the material development of production and its social form.¹⁵⁴

CHAPTER LII. THE CLASSES.

THE owners of mere labor-power, the owners of capital, and the landlords, whose respective sources of income are wages, profit and ground-rent, in other words, wage laborers, capitalists and landlords, form the three great classes of modern society resting upon the capitalist mode of production.

In England, modern society is indisputably developed most highly and classically in its economic structure. Nevertheless the stratification of classes does not appear in its pure form, even there. Middle and transition stages obliterate even here all definite boundaries, although much less in the rural districts than in the cities. However, this is immaterial for our analysis. We have seen that the continual tendency and law of development of capitalist production is to separate the means of production more and more from labor, and to concentrate the scattered means of production more and more in large groups, thereby transforming labor into wage labor and the means of production into capital. In keeping with this tendency we have, on the other hand, the independent separation of private land from capital and labor,¹⁵⁵ or the transformation of all property in land into a form of landed property corresponding to the capitalist mode of production.

The first question to be answered is this: What constitutes a class? And this follows naturally from another question, namely: What constitutes wage laborers, capitalists and landlords into three great social classes?

At first glance it might seem that the identity of their revenues and their sources of revenue does that. They are three great social groups, whose component elements, the individuals forming them, live on wages, profit and ground-rent, or by the utilization of their labor-power, their capital, and their private land.

However, from this point of view physicians and officials would also form two classes, for they belong to the two distinct social groups, and the revenues of their members flow from the same common source. The same would also be true of the infinite dissipation of interests and positions

created by the social division of labor among laborers, capitalists and landlords. For instance, the landlords are divided into owners of vineyards, farms, forests, mines, fisheries.

THE CIVIL WAR IN FRANCE, 1871

Translated by Friedrich Engels

This pamphlet was written as an official statement of the General Council of the International on the character and significance of the struggle of the Communards in the Paris Commune. Between the middle of April and the end of May 1871, while living in London, Marx collected and compiled English, French and German newspaper clippings on the progress of the French civil war, in which the radical workers of Paris strove against conservative forces from outside the city. Marx had access to French publications supported by the Commune, as well as various bourgeois periodicals published in London in English and French. He also had access to personal interpretations of events passed along by several leading figures in the Commune and associates such as Paul Lafargue and Peter Lavrov.

Marx originally intended to write an address to the workers of Paris and made such a motion to the meeting of the governing General Council of the International on 28 March, 1871, a proposal unanimously approved. Further developments in France made Marx think that the document should be instead directed to the working class of the world. At the 18 April meeting of the General Council, he passed along that suggestion by noting his desire to write on the “general tendency of the struggle.” The proposal was approved and Marx began writing the document.

The first edition of the pamphlet, a slight document of just 35 pages, was published in London on about 13 June, 1871 as “The Civil War in France: Address of the General Council of the International Working-Men’s Association.” Only 1000 copies of the first edition were printed and it quickly sold out, to be followed by a less expensive second edition with a print run of 2000. A third English edition, containing a number of corrections of errors, appeared later in that same year.

Introduction by Friedrich Engels

Thanks to the economic and political development of France since 1789, for 50 years the position of Paris has been such that no revolutions could break out there without assuming a proletarian character, that is to say, the proletariat, which had bought victory with its blood, would advance its own demands after victory. These demands were more or less unclear and even confused, corresponding to the state of evolution reached by the workers of Paris at the particular period, but in the last resort they all amounted to the abolition of the class antagonism between capitalist and workers. It is true that no one knew how this was to be brought about. But the demand itself, however indefinite it still was in its formulation, contained a threat to the existing order of society; the workers who put it forward were still armed; therefore the disarming of the workers was the first commandment for the bourgeois at the helm of the state. Hence, after every revolution won by the workers, a new struggle, ending with the defeat of the workers.

This happened for the first time in 1848. The liberal bourgeoisie of the parliamentary opposition held banquets for securing reform of the franchise, which was to ensure supremacy for their party. Forced more and more, in their struggle with the government, to appeal to the people, they had to allow the radical and republican strata of the bourgeoisie and petty bourgeoisie gradually to take the lead. But behind these stood the revolutionary workers, and since 1830, these had acquired far more political independence than the bourgeoisie, and even the republicans, suspected. At the moment of the crisis between the government and the opposition, the workers opened battle on the streets; Louis Philippe vanished, and with him the franchise reform; and in its place arose the republic, and indeed one which the victorious workers themselves designated as a “social” republic. No one, however, was clear as to what this social republic was to imply; not even the workers themselves. But they now had arms in their hands, and were a power in the state. Therefore, as soon as the bourgeois republicans in control felt something like firm ground under their feet, their first aim was to disarm the workers. This took place by driving them into the insurrection of June 1848 by direct breach of faith, by open defiance and the attempt to banish the unemployed to a distant province. The government had taken

care to have an overwhelming superiority of force. After five days' heroic struggle, the workers were defeated. And then followed a blood-bath of the defenceless prisoners, the likes of which as not been seen since the days of the civil wars which ushered in the downfall of the Roman republic. It was the first time that the bourgeoisie showed to what insane cruelties of revenge with will be goaded the moment the proletariat dares to take its stand against them as a separate class, with its own interests and demands. And yet 1848 was only child's play compared with their frenzy in 1871.

Punishment followed hard at heel. If the proletariat was not yet able to rule France, the bourgeoisie could no longer do so. At least not at that period, when the greater part of it was still monarchically inclined, and it was divided into three dynastic parties and a fourth republican party. Its internal dissensions allowed the adventurer Louis Bonaparte to take possession of all the commanding points – army, police, administrative machinery – and, on December 2, 1851, to explode the last stronghold of the bourgeoisie, the National Assembly. The Second Empire opened the exploitation of France by a gang of political and financial adventurers, but at the same time also an industrial development such as had never been possible under the narrow-minded and timorous system of Louis Philippe, with its exclusive domination by only a small section of the big bourgeoisie. Louis Bonaparte took the political power from the capitalists under the pretext of protecting them, the bourgeoisie, from the workers, and on the other hand the workers from them; but in return his rule encouraged speculation and industrial activity – in a word the rise and enrichment of the whole bourgeoisie to an extent hitherto unknown. To an even greater extent, it is true, corruption and mass robbery developed, clustering around the imperial court, and drawing their heavy percentages from this enrichment.

But the Second Empire was the appeal to the French chauvinism, the demand for the restoration of the frontiers of the First Empire, which had been lost in 1814, or at least those of the First Republic. A French empire within the frontiers of the old monarchy and, in fact, within the even more amputated frontiers of 1815 – such a thing was impossible for any long duration of time. Hence the necessity for brief wars and extension of frontiers. But no extension of frontiers was so dazzling to the imagination of the French chauvinists as the extension to the German left bank of the Rhine. One square mile on the Rhine was more to them than ten in the Alps or anywhere else. Given the Second Empire, the demand for the restoration

to France of the left bank of the Rhine, either all at once or piecemeal, was merely a question of time. The time came with the Austro-Prussian War of 1866; cheated of the anticipated “territorial compensation” by Bismarck, and by his own over-cunning, hesitating policy, there was not nothing left for Napoleon but war, which broke out in 1870 and drove him first to Sedan, and then to Wilhelmshöhe.

The inevitable result was the Paris Revolution of September 4, 1870. The empire collapsed like a house of cards, and the republic was again proclaimed. But the enemy was standing at the gates; the armies of the empire were either hopelessly beleaguered in Metz or held captive in Germany. In this emergency the people allowed the Paris Deputies to the former legislative body to constitute themselves into a “Government of National Defence.” This was the more readily conceded, since, for the purpose of defence, all Parisians capable of bearing arms had enrolled in the National Guard and were armed, so that now the workers constituted a great majority. But almost at once the antagonism between the almost completely bourgeois government and the armed proletariat broke into open conflict. On October 31, workers’ battalions stormed the town hall, and captured some members of the government. Treachery, the government’s direct breach of its undertakings, and the interventions of some petty-bourgeois battalions set them free again, and in order not to occasion the outbreak of civil war inside a city which was already beleaguered by a foreign power, the former government was left in office.

At last on January 28, 1871, Paris, almost starving, capitulated but with honors unprecedented in the history of war. The forts were surrendered, the outer wall disarmed, the weapons of the regiments of the line and of the Mobile Guard were handed over, and they themselves considered prisoners of war. But the National Guard kept its weapons and guns, and only entered into an armistice with the victors, who themselves did not dare enter Paris in triumph. They only dared to occupy a tiny corner of Paris, which, into the bargain, consisted partly of public parks, and even this they only occupied for a few days! And during this time they, who had maintained their encirclement of Paris for 131 days, were themselves encircled by the armed workers of Paris, who kept a sharp watch that no “Prussian” should overstep the narrow bounds of the corner ceded to the foreign conquerors. Such was the respect which the Paris workers inspired in the army before which all the armies of the empire had laid down their arms; and the

Prussian Junkers, who had come to take revenge at the very centre of the revolution, were compelled to stand by respectfully, and salute just precisely this armed revolution!

During the war the Paris workers had confined themselves to demanding the vigorous prosecution of the fight. But now, when peace had come after the capitulation of Paris, now, Thiers, the new head of government, was compelled to realize that the supremacy of the propertied classes – large landowners and capitalists – was in constant danger so long as the workers of Paris had arms in their hands. His first action was to attempt to disarm them. On March 18, he sent troops of the line with orders to rob the National Guard of the artillery belonging to it, which had been constructed during the siege of Paris and had been paid for by public subscription. The attempt failed; Paris mobilized as one man in defence of the guns, and war between Paris and the French government sitting at Versailles was declared. On March 26 the Paris Commune was elected and on March 28 it was proclaimed. The Central Committee of the National Guard, which up to then had carried on the government, handed in its resignation to the National Guard, after it had first decreed the abolition of the scandalous Paris “Morality Police.” On March 30 the Commune abolished conscription and the standing army, and declared that the National Guard, in which all citizens capable of bearing arms were to be enrolled, was to be the sole armed force. It remitted all payments of rent for dwelling houses from October 1870 until April, the amounts already paid to be reckoned to a future rental period, and stopped all sales of article pledged in the municipal pawnshops. On the same day the foreigners elected to the Commune were confirmed in office, because “the flag of the Commune is the flag of the World Republic.”

On April 1 it was decided that the highest salary received by any employee of the Commune, and therefore also by its members themselves, might not exceed 6,000 francs. On the following day the Commune decreed the separation of the Church from the State, and the abolition of all state payments for religious purposes as well as the transformation of all Church property into national property; as a result of which, on April 8, a decree excluding from the schools all religious symbols, pictures, dogmas, prayers – in a word, “all that belongs to the sphere of the individual’s conscience” – was ordered to be excluded from the schools, and this decree was gradually applied. On the 5th, day after day, in reply to the shooting of the

Commune's fighters captured by the Versailles troops, a decree was issued for imprisonment of hostages, but it was never carried into effect. On the 6th, the guillotine was brought out by the 137th battalion of the National guard, and publicly burnt, amid great popular rejoicing. On the 12th, the Commune decided that the Victory Column on the Place Vendôme, which had been cast from guns captured by Napoleon after the war of 1809, should be demolished as a symbol of chauvinism and incitement to national hatred. This decree was carried out on May 16. On April 16 the Commune ordered a statistical tabulation of factories which had been closed down by the manufacturers, and the working out of plans for the carrying on of these factories by workers formerly employed in them, who were to be organized in co-operative societies, and also plans for the organization of these co-operatives in one great union. On the 20th the Commune abolished night work for bakers, and also the workers' registration cards, which since the Second Empire had been run as a monopoly by police nominees – exploiters of the first rank; the issuing of these registration cards was transferred to the mayors of the 20 arrondissements of Paris. On April 30, the Commune ordered the closing of the pawnshops, on the ground that they were a private exploitation of labor, and were in contradiction with the right of the workers to their instruments of labor and to credit. On May 5 it ordered the demolition of the Chapel of Atonement, which had been built in expiation of the execution of Louis XVI.

Thus, from March 18 onwards the class character of the Paris movement, which had previously been pushed into the background by the fight against the foreign invaders, emerged sharply and clearly. As almost without exception, workers, or recognized representatives of the workers, sat in the Commune, its decision bore a decidedly proletarian character. Either they decreed reforms which the republican bourgeoisie had failed to pass solely out of cowardice, but which provided a necessary basis for the free activity of the working class – such as the realization of the principle that in relation to the state, religion is a purely private matter – or they promulgated decrees which were in the direct interests of the working class and to some extent cut deeply into the old order of society. In a beleaguered city, however, it was possible at most to make a start in the realization of all these measures. And from the beginning of May onwards all their energies were taken up by the fight against the ever-growing armies assembled by the Versailles government.

On April 7, the Versailles troops had captured the Seine crossing at Neuilly, on the western front of Paris; on the other hand, in an attack on the southern front on the 11th they were repulsed with heavy losses by General Eudes. Paris was continually bombarded and, moreover, by the very people who had stigmatized as a sacrilege the bombardment of the same city by the Prussians. These same people now begged the Prussian government for the hasty return of the French soldiers taken prisoner at Sedan and Metz, in order that they might recapture Paris for them. From the beginning of May the gradual arrival of these troops gave the Versailles forces a decided ascendancy. This already became evident when, on April 23, Thiers broke off the negotiations for the exchange, proposed by Commune, of the Archbishop of Paris and a whole number of other priests held hostages in Paris, for only one man, Blanqui, who had twice been elected to the Commune but was a prisoner in Clairvaux. And even more in the changed language of Thiers; previously procrastinating and equivocal, he now suddenly became insolent, threatening, brutal. The Versailles forces took the redoubt of Moulin Saquet on the southern front, on May 3; on the 9th, Fort Issy, which had been completely reduced to ruins by gunfire; and on the 14th, Fort Vanves. On the western front they advanced gradually, capturing the numerous villages and buildings which extended up to the city wall, until they reached the main wall itself; on the 21st, thanks to treachery and the carelessness of the National Guards stationed there, they succeeded in forcing their way into the city. The Prussians who held the northern and eastern forts allowed the Versailles troops to advance across the land north of the city, which was forbidden ground to them under the armistice, and thus to march forward and attack on a long front, which the Parisians naturally thought covered by the armistice, and therefore held only with weak forces. As a result of this, only a weak resistance was put up in the western half of Paris, in the luxury city proper; it grew stronger and more tenacious the nearer the incoming troops approached the eastern half, the real working class city.

It was only after eight days' fighting that the last defender of the Commune were overwhelmed on the heights of Belleville and Menilmontant; and then the massacre of defenceless men, women, and children, which had been raging all through the week on an increasing scale, reached its zenith. The breechloaders could no longer kill fast enough; the vanquished workers were shot down in hundred by mitrailleuse

fire. The “Wall of the Federals” at the Pere Lachaise cemetery, where the final mass murder was consummated, is still standing today, a mute but eloquent testimony to the savagery of which the ruling class is capable as soon as the working class dares to come out for its rights. Then came the mass arrests; when the slaughter of them all proved to be impossible, the shooting of victims arbitrarily selected from the prisoners’ ranks, and the removal of the rest to great camps where they awaited trial by courts-martial. The Prussian troops surrounding the northern half of Paris had orders not to allow any fugitives to pass; but the officers often shut their eyes when the soldiers paid more obedience to the dictates of humanity than to those of the General Staff; particularly, honor is due to the Saxon army corps, which behaved very humanely and let through many workers who were obviously fighters for the Commune.

Friedrich Engels

London, on the 20th anniversary of the Paris Commune, March 18, 1891

Postscript to introduction by Friedrich Engels

I did not anticipate that I would be asked to prepare a new edition of the Address of the General Council of the International on The Civil War in France, and to write an introduction to it. Therefore I can only touch briefly here on the most important points.

I am prefacing the longer work mentioned above by the two shorter addresses of the General Council on the Franco-Prussian War. In the first place, because the second of these, which itself cannot be fully understood without the first, is referred to in The Civil War. But also because these two Addresses, likewise drafted by Marx, are, no less than The Civil War, outstanding examples of the author's remarkable gift, first proved in The Eighteenth Brumaire of Louis Bonaparte, for grasping clearly the character, the import, and the necessary consequences of great historical events, at a time when these events are still in process before our eyes, or have only just taken place. And, finally, because we in Germany are still having to endure the consequences which Marx prophesied would follow from these events.

Has that which was declared in the first Address not come to pass: that if Germany's defensive war against Louis Bonaparte degenerated into a war of conquest against the French people, all the misfortunes which befell Germany after the so-called wars of liberation would revive again with renewed intensity? Have we not had a further 20 years of Bismarck's government, the Exceptional Law and the anti-socialist campaign taking the place of the prosecutions of "demagogues", with the same arbitrary police measures and with literally the same staggering interpretations of the law?

And has not the prophecy been proved to the letter that the annexation of Alsace-Lorraine would "force France into the arms of Russia", and that after this annexation Germany must either become the avowed tool of Russia, or must, after some short respite, arm for a new war, and, moreover, "a war with the combines Slavonic and Roman races"? Has not the annexation of the French provinces driven France into the arms of Russia? Has not Bismarck for fully 20 years vainly wooed the favor of the tsar, wooed it with services even more lowly than those which little Prussia, before it became the "first power in Europe", was wont to lay at Holy

Russia's feet? And is there not every day hanging over our heads the Damocles' sword of war, on the first day of which all the chartered covenants of princes will be scattered like chaff; a war of which nothing is certain but the absolute uncertainty of its outcome; a race war which will subject the whole of Europe to devastation by 15 or 20 million armed men, and is only not already raging because even the strongest of the great military states shrinks before the absolute incalculability of its final outcome?

All the more is it our duty to make again accessible to the German workers these brilliant proofs, now half-forgotten, of the far-sightedness of the international working class policy in 1870.

What is true of these two Addresses is also true of The Civil War in France. On March 28, the last fighters of the Commune succumbed to superior forces on the slopes of Belleville; and only two days later, on May 30, Marx read to the General Council the work in which the historical significance of the Paris Commune is delineated in short powerful strokes, but with such clearness, and above all such truth, as has never again been attained on all the mass of literature which has been written on this subject.

Thanks to the economic and political development of France since 1789, for 50 years the positions in Paris has been such that no revolutions could break out there without assuming a proletarian character, that is to say, without the proletariat, which had bought victory with its blood, advancing its own demands after victory. These demands were more or less unclear and even confused, corresponding to the state of evolution reached by the workers of Paris at the particular period, but in the last resort they all amounted to the abolition of the class antagonism between capitalist and workers. It is true that no one knew how this was to be brought about. But the demand itself, however indefinite it still was in its formulation, contained a threat to the existing order of society; the workers who put it forward were still armed; therefore the disarming of the workers was the first commandment for the bourgeois at the helm of the state. Hence, after every revolution won by the workers, a new struggle, ending with the defeat of the workers.

This happened for the first time in 1848. The liberal bourgeoisie of the parliamentary opposition held banquets for securing reform of the franchise, which was to ensure supremacy for their party. Forced more and more, in their struggle with the government, to appeal to the people, they had to

allow the radical and republican strata of the bourgeoisie and petty bourgeoisie gradually to take the lead. But behind these stood the revolutionary workers, and since 1830, these had acquired far more political independence than the bourgeoisie, and even the republicans, suspected. At the moment of the crisis between the government and the opposition, the workers opened battle on the streets; Louis Philippe vanished, and with him the franchise reform; and in its place arose the republic, and indeed one which the victorious workers themselves designated as a “social” republic. No one, however, was clear as to what this social republic was to imply; not even the workers themselves. But they now had arms in their hands, and were a power in the state. Therefore, as soon as the bourgeois republicans in control felt something like firm ground under their feet, their first aim was to disarm the workers. This took place by driving them into the insurrection of June 1848 by direct breach of faith, by open defiance and the attempt to banish the unemployed to a distant province. The government had taken care to have an overwhelming superiority of force. After five days’ heroic struggle, the workers were defeated. And then followed a blood-bath of the defenceless prisoners, the likes of which has not been seen since the days of the civil wars which ushered in the downfall of the Roman republic. It was the first time that the bourgeoisie showed to what insane cruelties of revenge it will be goaded the moment the proletariat dares to take its stand against them as a separate class, with its own interests and demands. And yet 1848 was only a child’s play compared with their frenzy in 1871.

Punishment followed hard at heel. If the proletariat was not yet able to rule France, the bourgeoisie could no longer do so. At least not at that period, when the greater part of it was still monarchically inclined, and it was divided into three dynastic parties and a fourth republican party. Its internal dissensions allowed the adventurer Louis Bonaparte to take possession of all the commanding points — army, police, administrative machinery — and, on December 2, 1851, to explode the last stronghold of the bourgeoisie, the National Assembly. The Second Empire opened the exploitation of France by a gang of political and financial adventurers, but at the same time also an industrial development such as had never been possible under the narrow-minded and timorous system of Louis Philippe, with its exclusive domination by only a small section of the big bourgeoisie. Louis Bonaparte took the political power from the capitalists under the pretext of protecting them, the bourgeoisie, from the workers, and on the

other hand the workers from them; but in return his rule encouraged speculation and industrial activity — in a word the rise and enrichment of the whole bourgeoisie to an extent hitherto unknown. To an even greater extent, it is true, corruption and mass robbery developed, clustering around the imperial court, and drawing their heavy percentages from this enrichment.

But the Second Empire was the appeal to the French chauvinism, the demand for the restoration of the frontiers of the First Empire, which had been lost in 1814, or at least those of the First Republic. A French empire within the frontiers of the old monarchy and, in fact, within the even more amputated frontiers of 1815 — such a thing was impossible for any long duration of time. Hence the necessity for brief wars and extension of frontiers. But no extension of frontiers was so dazzling to the imagination of the French chauvinists as the extension to the German left bank of the Rhine. One square mile on the Rhine was more to them than ten in the Alps or anywhere else. Given the Second Empire, the demand for the restoration to France of the left bank of the Rhine, either all at once or piecemeal, was merely a question of time. The time came with the Austro-Prussian War of 1866; cheated of the anticipated “territorial compensation” by Bismarck, and by his own over-cunning, hesitating policy, there was not nothing left for Napoleon but war, which broke out in 1870 and drove him first to Sedan, and then to Wilhelmshöhe.

The inevitable result was the Paris Revolution of September 4, 1870. The empire collapsed like a house of cards, and the republic was again proclaimed. But the enemy was standing at the gates; the armies of the empire were either hopelessly beleaguered in Metz or held captive in Germany. In this emergency the people allowed the Paris Deputies to the former legislative body to constitute themselves into a “Government of National Defence”. This was the more readily conceded, since, for the purpose of defence, all Parisians capable of bearing arms had enrolled in the National Guard and were armed, so that now the workers constituted a great majority. But almost at once the antagonism between the almost completely bourgeois government and the armed proletariat broke into open conflict. On October 31, workers’ battalions stormed the town hall, and captured some members of the government. Treachery, the government’s direct breach of its undertakings, and the interventions of some petty-bourgeois battalions set them free again, and in order not to occasion the outbreak of

civil war inside a city which was already beleaguered by a foreign power, the former government was left in office.

At last on January 8, 1871, Paris, almost starving, capitulated but with honors unprecedented in the history of war. The forts were surrendered, the outer wall disarmed, the weapons of the regiments of the line and of the Mobile Guard were handed over, and they themselves considered prisoners of war. But the National Guard kept its weapons and guns, and only entered into an armistice with the victors, who themselves did not dare enter Paris in triumph. They only dared to occupy a tiny corner of Paris, which, into the bargain, consisted partly of public parks, and even this they only occupied for a few days! And during this time they, who had maintained their encirclement of Paris for 131 days, were themselves encircled by the armed workers of Paris, who kept a sharp watch that no "Prussian" should overstep the narrow bounds of the corner ceded to the foreign conquerors. Such was the respect which the Paris workers inspired in the army before which all the armies of the empire had laid down their arms; and the Prussian Junkers, who had come to take revenge at the very centre of the revolution, were compelled to stand by respectfully, and salute just precisely this armed revolution!

During the war the Paris workers had confined themselves to demanding the vigorous prosecution of the fight. But now, when peace had come after the capitulation of Paris, now, Thiers, the new head of government, was compelled to realize that the supremacy of the propertied classes — large landowners and capitalists — was in constant danger so long as the workers of Paris had arms in their hands. His first action was to attempt to disarm them. On March 18, he sent troops of the line with orders to rob the National Guard of the artillery belonging to it, which had been constructed during the siege of Paris and had been paid for by subscription. The attempt failed; Paris mobilized as one man in defence of the guns, and war between Paris and the French government sitting at Versailles was declared. On March 26 the Paris Commune was elected and on March 28 it was proclaimed. The Central Committee of the National Guard, which up to then had carried on the government, handed in its resignation to the National Guard, after it had first decreed the abolition of the scandalous Paris "Morality Police". On March 30 the Commune abolished conscription and the standing army, and declared that the National Guard, in which all citizens capable of bearing arms were to be enrolled, was to be the sole

armed force. It remitted all payments of rent for dwelling houses from October 1870 until April, the amounts already paid to be reckoned to a future rental period, and stopped all sales of article pledged in the municipal pawnshops. On the same day the foreigners elected to the Commune were confirmed in office, because “the flag of the Commune is the flag of the World Republic”.

On April 1 it was decided that the highest salary received by any employee of the Commune, and therefore also by its members themselves, might not exceed 6,000 francs. On the following day the Commune decreed the separation of the Church from the State, and the abolition of all state payments for religious purposes as well as the transformation of all Church property into national property; as a result of which, on April 8, a decree excluding from the schools all religious symbols, pictures, dogmas, prayers — in a word, “all that belongs to the sphere of the individual’s conscience” — was ordered to be excluded from the schools, and this decree was gradually applied. On the 5th, in reply to the shooting, in reply to the shooting, day after day, of the Commune’s fighters captured by the Versailles troops, a decree was issued for imprisonment of hostages, but it was never carried into effect. On the 6th, the guillotine was brought out by the 137th battalion of the National guard, and publicly burnt, amid great popular rejoicing. On the 12th, the Commune decided that the Victory Column on the Place Vendome, which had been cast from guns captured by napoleon after the war of 1809, should be demolished as a symbol of chauvinism and incitement to national hatred. This decree was carried out on May 16. On April 16 the Commune ordered a statistical tabulation of factories which had been closed down by the manufacturers, and the working out of plans for the carrying on of these factories by workers formerly employed in them, who were to be organized in co-operative societies, and also plans for the organization of these co-operatives in one great union. On the 20th the Commune abolished night work for bakers, and also the workers’ registration cards, which since the Second Empire had been run as a monopoly by police nominees — exploiters of the first rank; the issuing of these registration cards was transferred to the mayors of the 20 arrondissements of Paris. On April 30, the Commune ordered the closing of the pawnshops, on the ground that they were a private exploitation of labor, and were in contradiction with the right of the workers to their instruments of labor and to credit. On May 5 it ordered the demolition of

the Chapel of Atonement, which had been built in expiation of the execution of Louis XVI.

Thus, from March 18 onwards the class character of the Paris movement, which had previously been pushed into the background by the fight against the foreign invaders, emerged sharply and clearly. As almost without exception, workers, or recognized representatives of the workers, sat in the Commune, its decision bore a decidedly proletarian character. Either they decreed reforms which the republican bourgeoisie had failed to pass solely out of cowardice, but which provided a necessary basis for the free activity of the working class — such as the realization of the principle that in relation to the state, religion is a purely private matter — or they promulgated decrees which were in the direct interests of the working class and to some extent cut deeply into the old order of society. In a beleaguered city, however, it was possible at most to make a start in the realization of all these measures. And from the beginning of May onwards all their energies were taken up by the fight against the ever-growing armies assembled by the Versailles government.

On April 7, the Versailles troops had captured the Seine crossing at Neuilly, on the western front of Paris; on the other hand, in an attack on the southern front on the 11th they were repulsed with heavy losses by General Eudes. Paris was continually bombarded and, moreover, by the very people who had stigmatized as a sacrilege the bombardment of the same city by the Prussians. These same people now begged the Prussian government for the hasty return of the French soldiers taken prisoner at Sedan and Metz, in order that they might recapture Paris for them. From the beginning of May the gradual arrival of these troops gave the Versailles forces a decided ascendancy. This already became evident when, on April 23, Thiers broke off the negotiations for the exchange, proposed by Commune, of the Archbishop of Paris and a whole number of other priests held hostages in Paris, for only one man, Blanqui, who had twice been elected to the Commune but was a prisoner in Clairvaux. And even more in the changed language of Thiers; previously procrastinating and equivocal, he now suddenly became insolent, threatening, brutal. The Versailles forces took the redoubt of Moulin Saquet on the southern front, on May 3; on the 9th, Fort Issy, which had been completely reduced to ruins by gunfire; and on the 14th, Fort Vanves. On the western front they advanced gradually, capturing the numerous villages and building which extended up to the city wall, until

they reached the main wall itself; on the 21st, thanks to treachery and the carelessness of the National Guards stationed there, they succeeded in forcing their way into the city. The Prussians who held the northern and eastern forts allowed the Versailles troops to advance across the land north of the city, which was forbidden ground to them under the armistice, and thus to march forward and attack on a long front, which the Parisians naturally thought covered by the armistice, and therefore held only with weak forces. As a result of this, only a weak resistance was put up in the western half of Paris, in the luxury city proper; it grew stronger and more tenacious the nearer the incoming troops approached the eastern half, the real working class city.

It was only after eight days' fighting that the last defender of the Commune were overwhelmed on the heights of Belleville and Menilmontant; and then the massacre of defenceless men, women, and children, which had been raging all through the week on an increasing scale, reached its zenith. The breechloaders could no longer kill fast enough; the vanquished workers were shot down in hundred by mitrailleuse fire. the "Wall of the Federals" at the Pere Lachaise cemetery, where the final mass murder was consummated, is still standing today, a mute but eloquent testimony to the savagery of which the ruling class is capable as soon as the working class dares to come out for its rights. Then came the mass arrests; when the slaughter of them all proved to be impossible, the shooting of victims arbitrarily selected from the prisoners' ranks, and the removal of the rest to great camps where they awaited trial by courts-martial. The Prussian troops surrounding the northern half of Paris had orders not to allow any fugitives to pass; but the officers often shut their eyes when the soldiers paid more obedience to the dictates of humanity than to those of the General Staff; particularly, honor is due to the Saxon army corps, which behaved very humanely and let through many workers who were obviously fighters for the Commune.

If today, we look back at the activity and historical significance of the Paris Commune of 1871, we shall find it necessary to make a few additions to the account given in *The Civil War in France*.

The members of the Commune were divided into a majority of the Blanquists, who had also been predominant in the Central Committee of the National Guard; and a minority, members of the International Working Men's Association, chiefly consisting of adherents of the Proudhon school

of socialism. The great majority of the Blanquists at that time were socialist only by revolutionary and proletarian instinct; only a few had attained greater clarity on the essential principles, through Vaillant, who was familiar with German scientific socialism. It is therefore comprehensible that in the economic sphere much was left undone which, according to our view today, the Commune ought to have done. The hardest thing to understand is certainly the holy awe with which they remained standing respectfully outside the gates of the Bank of France. This was also a serious political mistake. The bank in the hands of the Commune — this would have been worth more than 10,000 hostages. It would have meant the pressure of the whole of the French bourgeoisie on the Versailles government in favor of peace with the Commune. but what is still more wonderful is the correctness of so much that was actually done by the Commune, composed as it was of Blanquists and Proudhonists. naturally, the Proudhonists were chiefly responsible for the economic decrees of the Commune, both for their praiseworthy and their unpraiseworthy aspects; as the Blanquists were for its political actions and omissions. And in both cases the irony of history willed — as is usual when doctrinaires come to the helm — that both did the opposite of what the doctrines of their school proscribed.

Proudhon, the Socialist of the small peasant and master-craftsman, regarded association with positive hatred. He said of it that there was more bad than good in it; that it was by nature sterile, even harmful, because it was a fetter on the freedom of the workers; that it was a pure dogma, unproductive and burdensome, in conflict as much with the freedom of the workers as with economy of labor; that its disadvantages multiplied more swiftly than its advantages; that, as compared with it, competition, division of labor and private property were economic forces. Only for the exceptional cases — as Proudhon called them — of large-scale industry and large industrial units, such as railways, was there any place for the association of workers. (Cf. *Idee Generale de la Revolution*, 3 etude.)

By 1871, even in Paris, the centre of handicrafts, large-scale industry had already so much ceased to be an exceptional case that by far the most important decree of the Commune instituted an organization of large-scale industry and even of manufacture which was not based only on the association of workers in each factor, but also aimed at combining all these associations in one great union; in short an organization which, as Marx

quite rightly says in *The Civil War*, must necessarily have led in the end to communism, that is to say, the direct antithesis of the Proudhon doctrine. And, therefore, the Commune was also the grave of the Proudhon school of socialism. Today this school has vanished from French working class circles; among them now, among the Possibilists no less than among the “Marxists”, Marx’s theory rules unchallenged. Only among the “radical” bourgeoisie are there still Proudhonists.

The Blanquists fared no better. Brought up in the school of conspiracy, and held together by the strict discipline which went with it, they started out from the viewpoint that a relatively small number of resolute, well-organized men would be able, at a given favorable moment, not only seize the helm of state, but also by energetic and relentless action, to keep power until they succeeded in drawing the mass of the people into the revolution and ranging them round the small band of leaders. this conception involved, above all, the strictest dictatorship and centralization of all power in the hands of the new revolutionary government. And what did the Commune, with its majority of these same Blanquists, actually do? In all its proclamations to the French Communes with Paris, a national organization, which for the first time was really to be created by the nation itself. It was precisely the oppressing power of the former centralized government, army, political police and bureaucracy, which napoleon had created in 1798 and since then had been taken over by every new government as a welcome instrument and used against its opponents, it was precisely this power which was to fall everywhere, just as it had already fallen in Paris.

From the outset the Commune was compelled to recognize that the working class, once come to power, could not manage with the old state machine; that in order not to lose again its only just conquered supremacy, this working class must, on the one hand, do away with all the old repressive machinery previously used against it itself, and, on the other, safeguard itself against its own deputies and officials, by declaring them all, without exception, subject to recall at any moment. What had been the characteristic attribute of the former state? Society had created its own organs to look after its common interests, originally through simple division of labor. But these organs, at whose head was the state power, had in the course of time, in pursuance of their own special interests, transformed themselves from the servants of society into the masters of society, as can be seen, for example, not only in the hereditary monarchy, but equally also

in the democratic republic. Nowhere do “politicians” form a more separate, powerful section of the nation than in North America. There, each of the two great parties which alternately succeed each other in power is itself in turn controlled by people who make a business of politics, who speculate on seats in the legislative assemblies of the Union as well as of the separate states, or who make a living by carrying on agitation for their party and on its victory are rewarded with positions.

It is well known that the Americans have been striving for 30 years to shake off this yoke, which has become intolerable, and that in spite of all they can do they continue to stink ever deeper in this swamp of corruption. It is precisely in America that we see best how there takes place this process of the state power making itself independent in relation to society, whose mere instrument it was originally intended to be. Here there exists no dynasty, no nobility, no standing army, beyond the few men keeping watch on the Indians, no bureaucracy with permanent posts or the right to pensions. and nevertheless we find here two great gangs of political speculators, who alternately take possession of the state power and exploit it by the most corrupt means and for the most corrupt ends — and the nation is powerless against these two great cartels of politicians, who are ostensibly its servants, but in reality exploit and plunder it.

Against this transformation of the state and the organs of the state from servants of society into masters of society — an inevitable transformation in all previous states — the Commune made use of two infallible expedients. In this first place, it filled all posts — administrative, judicial, and educational — by election on the basis of universal suffrage of all concerned, with the right of the same electors to recall their delegate at any time. And in the second place, all officials, high or low, were paid only the wages received by other workers. The highest salary paid by the Commune to anyone was 6,000 francs. In this way an effective barrier to place-hunting and careerism was set up, even apart from the binding mandates to delegates to representative bodies which were also added in profusion.

This shattering of the former state power and its replacement by a new and really democratic state is described in detail in the third section of *The Civil War*. But it was necessary to dwell briefly here once more on some of its features, because in Germany particularly the superstitious belief in the state has been carried over from philosophy into the general consciousness of the bourgeoisie and even to many workers. According to the

philosophical notion, the state is the “realization of the idea” or the Kingdom of God on earth, translated into philosophical terms, the sphere in which eternal truth and justice is or should be realized. And from this follows a superstitious reverence for the state and everything connected with it, which takes roots the more readily as people from their childhood are accustomed to imagine that the affairs and interests common to the whole of society could not be looked after otherwise than as they have been looked after in the past, that is, through the state and its well-paid officials. And people think they have taken quite an extraordinary bold step forward when they have rid themselves of belief in hereditary monarchy and swear by the democratic republic. In reality, however, the state is nothing but a machine for the oppression of one class by another, and indeed in the democratic republic no less than in the monarchy; and at best an evil inherited by the proletariat after its victorious struggle for class supremacy, whose worst sides the proletariat, just like the Commune, cannot avoid having to lop off at the earliest possible moment, until such time as a new generation, reared in new and free social conditions, will be able to throw the entire lumber of the state on the scrap-heap.

Of late, the Social-Democratic philistine has once more been filled with wholesome terror at the words: Dictatorship of the Proletariat. Well and good, gentlemen, do you want to know what this dictatorship looks like? Look at the Paris Commune. That was the Dictatorship of the Proletariat.

Friedrich Engels

London, on the 20th anniversary of the Paris Commune, March 18, 1891.

The Begining of the Franco-Prussian War

In the Inaugural Address of the International Working Men's Association, of November 1864, we said:

“If the emancipation of the working classes requires their fraternal concurrence, how are they to fulfill that great mission with a foreign policy in pursuit of criminal designs, playing upon national prejudices, and squandering in piratical wars the people's blood and treasure?”

We defined the foreign policy aimed at by the International in these words:

“Vindicate the simple laws of morals and justice, which ought to govern the relations of private individuals, as the laws paramount of the intercourse of nations.”

No wonder that Louis Bonaparte, who usurped power by exploiting the war of classes in France, and perpetuated it by periodical wars abroad, should, from the first, have treated the International as a dangerous foe. On the eve of the plebiscite he ordered a raid on the members of the Administrative Committee of the International Working Men's Association through France, at Paris, Lyons, Rouen, Marseilles, Brest, etc., on the pretext that the International was a secret society dabbling in a complot for his assassination, a pretext soon after exposed in its full absurdity by his own judges. What was the real crime of the French branches of the International? They told the French people publicly and emphatically that voting the plebiscite was voting despotism at home and war abroad. It has been, in fact, their work that in all the great towns, in all the industrial centres of France, the working class rose like one man to reject the plebiscite. Unfortunately, the balance was turned by the heavy ignorance of the rural districts. The stock exchanges, the cabinets, the ruling classes, and the press of Europe celebrated the plebiscite as a signal victory of the French emperor over the French working class; and it was the signal for the assassination, not of an individual, but of nations.

The war plot of July 1870 is but an amended edition of the coup d'état of December 1851. At first view, the thing seemed so absurd that France would not believe in its real good earnest. It rather believed the deputy denouncing the ministerial war talk as a mere stock-jobbing trick. When, on

July 15, war was at last officially announced to the Corps Legislatif, the whole Opposition refused to vote the preliminary subsidies ““ even Thiers branded it as “detestable”; all the independent journals of Paris condemned it, and, wonderful to relate, the provincial press joined in almost unanimously.

Meanwhile, the Paris members of the International had against set to work. In the Reveil of July 12, they published their manifesto “to the Workmen of all Nations”, from which we extract the following few passages:

“Once more,” they say, “on the pretext of european equilibrium, of national honor, the peace of the world is menaced by political ambitions. French, German, Spanish workmen! Let our voices unite in one cry of reprobation against war!

“War for a question of preponderance or a dynasty can, in the eyes of workmen, be nothing but a criminal absurdity. In answer to the warlike proclamations of those who exempt themselves from the blood tax, and find in public misfortunes a source of fresh speculations, we protest, we who want peace, labor, and liberty!

“Brothers in Germany! Our division would only result in the complete triumph of the despotism on both sides of the Rhine...

“Workmen of all countries! Whatever may for the present become of our common efforts, we, the members of the International Working Men’s Association, who know of no frontiers, we send you, as a pledge of indissoluble solidarity, the good wishes and the salutations of the workmen of France.”

This manifesto of our Paris section was followed by numerous similar French addresses, of which we can here only quote the declaration of Neuilly-sur-Seine, published in the Marseillaise of July 22:

“The war, is it just? No! The war, is it national? No! It is merely dynastic. In the name of humanity, or democracy, and the true interests of France, we adhere completely and energetically to the protestation of the International against the war.”

These protestations expressed the true sentiments of the French working people, as was soon shown by a curious incident. The Band of the 10th of December, first organized under the presidency of Louis Bonaparte, having been masqueraded into blouses and let loose on the streets of Paris, there to perform the contortions of war fever, the real workmen of the Faubourgs

came forward with public peace demonstrations so overwhelming that Pietri, the Prefect of Police, thought it prudent to stop at once all further street politics, on the plea that the real Paris people had given sufficient vent to their pent-up patriotism and exuberant war enthusiasm.

Whatever may be the incidents of Louis Bonaparte's war with Prussia, the death-knell of the Second Empire has already sounded at Paris. It will end, as it began, by a parody. But let us not forget that it is the governments and the ruling classes of Europe who enabled Louis Bonaparte to play during 18 years the ferocious farce of the Restored Empire.

On the German side, the war is a war of defence; but who put Germany to the necessity of defending herself? Who enabled Louis Bonaparte to wage war upon her? Prussia! It was Bismarck who conspired with that very same Louis Bonaparte for the purpose of crushing popular opposition at home, and annexing Germany to the Hohenzollern dynasty. If the battle of Sadowa had been lost instead of being won, French battalions would have overrun Germany as the allies of Prussia. After her victory, did Prussia dream one moment of opposing a free Germany to an enslaved France? Just the contrary. While carefully preserving all the native beauties of her old system, she super-added all the tricks of the Second Empire, its real despotism, and its mock democratism, its political shams and its financial jobs, its high-flown talk and its low legerdemains. The Bonapartist regime, which till then only flourished on one side of the Rhine, had now got its counterfeit on the other. From such a state of things, what else could result but war?

If the German working class allows the present war to lose its strictly defensive character and to degenerate into a war against the French people, victory or defeat will prove alike disastrous. All the miseries that befell Germany after her war of independence will revive with accumulated intensity.

The principles of the International are, however, too widely spread and too firmly rooted amongst the German working class to apprehend such a sad consummation. The voices of the French workmen had re-echoed from Germany. A mass meeting of workmen, held at Brunswick on July 16, expressed its full concurrence with the Paris manifesto, spurned the idea of national antagonism to France, and wound up its resolutions with these words:

“We are the enemies of all wars, but above all of dynastic wars. ... With deep sorrow and grief we are forced to undergo a defensive war as an unavoidable evil; but we call, at the same time, upon the whole German working class to render the recurrence of such an immense social misfortune impossible by vindicating for the peoples themselves the power to decide on peace and war, and making them masters of their own destinies.”

At Chemnitz, a meeting of delegates, representing 50,000 Saxon workmen, adopted unanimously a resolution to this effect:

“In the name of German Democracy, and especially of the workmen forming the Democratic Socialist Party, we declare the present war to be exclusively dynastic.... We are happy to grasp the fraternal hand stretched out to us by the workmen of France.... Mindful of the watchword of the International Working Men’s Association: Proletarians of all countries, unite, we shall never forget that the workmen of all countries are our friends and the despots of all countries our enemies.”

The Berlin branch of the International has also replied to the Paris manifesto:

“We,” they say, “join with heart and hand your protestation.... Solemnly, we promise that neither the sound of the trumpets, nor the roar of the cannon, neither victory nor defeat, shall divert us from our common work for the union of the children of toil of all countries.”

Be it so!

In the background of this suicidal strike looms the dark figure of Russia. It is an ominous sign that the signal for the present war should have been given at the moment when the Moscovite government had just finished its strategic lines of railway and was already massing troops in the direction of the Pruth. Whatever sympathy the Germans may justly claim in a war of defense against Bonapartist aggression, they would forfeit at once by allowing the Prussian government to call for, or accept the help of, the Cossack. Let them remember that after their war of independence against the first Napoleon, Germany lay for generations prostrate at the feet of the tsar.

The English working class stretch the hand of fellowship to the French and German working people. They feel deeply convinced that whatever turn the impending horrid war may take, the alliance of the working classes of all countries will ultimately kill war. The very fact that while official France

and Germany are rushing into a fratricidal feud, the workmen of France and Germany send each other messages of peace and goodwill; this great fact, unparalleled in the history of the past, opens the vista of a brighter future. It proves that in contrast to old society, with its economical miseries and its political delirium, a new society is springing up, whose International rule will be Peace, because its national ruler will be everywhere the same ““ Labor! The pioneer of that new society is the International Working Men’s Association.

Prussian Occupation of France

In our first manifesto of the 23rd of July, we said:

“The death-knell of the Second Empire has already sounded at Paris. It will end, as it began, by a parody. But let us not forget that it is the governments and the ruling classes of Europe who enabled Louis Bonaparte to play during 18 years the ferocious farce of the Restored Empire.”

Thus, even before war operations had actually set in, we treated the Bonapartist bubble as a thing of the past.

If we were not mistaken as to the vitality of the Second Empire, we were not wrong in our apprehension lest the German war should “lose its strictly defensive character and degenerate into a war against the French people”. The war of defense ended, in point of fact, with the surrender of Louis Bonaparte, the Sedan capitulation, and the proclamation of the republic at Paris. But long before these events, the very moment that the utter rottenness of the imperialist arms became evident, the Prussian military camarilla had resolved upon conquest. There lay an ugly obstacle in their way ““ King William’s own proclamations at the commencement of the war.

In a speech from the throne to the North German Diet, he had solemnly declared to make war upon the emperor of the French and not upon the French nation, where he said:

“The Emperor Napoleon having made by land and sea an attack on the German nation, which desired and still desires to live in peace with the French people, I have assumed the command of the German armies to repel his aggression, and I have been led by military events to cross the frontiers of France.”

Not content to assert the defensive character of the war by the statement that he only assumed the command of the German armies “to repel aggression”, he added that he was only “led by military events” to cross the frontiers of France. A defensive war does, of course, not exclude offensive operations, dictated by military events.

Thus, the pious king stood pledged before France and the world to a strictly defensive war. How to release him from his solemn pledge? The stage managers had to exhibit him as reluctantly yielding to the irresistible

behest of the German nation. They at once gave the cue to the liberal German middle class, with its professors, its capitalists, its aldermen, and its penmen. That middle class, which, in its struggles for civil liberty, had, from 1846 to 1870, been exhibiting an unexampled spectacle of irresolution, incapacity and cowardice, felt, of course, highly delighted to bestride the European scene as the roaring lion of German patriotism. It re-vindicated its civic independence to affecting to force upon the Prussian government the secret designs of that same government. It does penance for its long-continued, and almost religious, faith in Louis Bonaparte's infallibility, but shouting for the dismemberment of the French republic. Let us, for a moment, listen to the special pleadings of those stout-hearted patriots!

They dare not pretend that the people of Alsace and Lorraine pant for the German embrace; quite the contrary. To punish their French patriotism, Strasbourg, a town with an independent citadel commanding it, has for six days been wantonly and fiendishly bombarded by "German" explosive shells, setting it on fire, and killing great numbers of its defenceless inhabitants! Yet, the soil of those provinces once upon a time belonged to the whilom German empire. Hence, it seems, the soil and the human beings grown on it must be confiscated as imprescriptible German property. If the map of Europe is to be re-made in the antiquary's vein, let us by no means forget that the Elector of Brandenburg, for his Prussian dominions, was the vassals of the Polish republic.

The more knowing patriots, however, require Alsace and the German-speaking Lorraine as a "material guarantee" against French aggression. As this contemptible plea has bewildered many weak-minded people, we are bound to enter more fully upon it.

There is no doubt that the general configuration of Alsace, as compared with the opposite bank of the Rhine, and the presence of a large fortified town like Strasbourg, about halfway between Basle and Germersheim, very much favour a French invasion of South Germany, while they offer peculiar difficulties to an invasion of France from South Germany. There is, further, no doubt that the addition of Alsace and German-speaking Lorraine would give South Germany a much stronger frontier, inasmuch as she would then be the master of the crest of the Vosges mountains in its whole length, and of the fortresses which cover its northern passes. If Metz were annexed as well, France would certainly for the moment be deprived of her two

principal bases of operation against Germany, but that would not prevent her from concentrating a fresh one at Nancy or Verdun. While Germany owns Coblenz, Mayence, Germersheim, Rastatt, and Ulm, all bases of operation against France, and plentifully made use of in this war, with what show of fair play can she begrudge France Strasbourg and Metz, the only two fortresses of any importance she has on that side? Moreover, Strasbourg endangers South Germany only while South Germany is a separate power from North Germany. From 1792 to 1795, South Germany was never invaded from that direction, because Prussia was a party to the war against the French Revolution; but as soon as Prussia made a peace of her own in 1795, and left the South to shift for itself, the invasions of South Germany with Strasbourg as a base began and continued till 1809. The fact is, a united Germany can always render Strasbourg and any French army in Alsace innocuous by concentrating all her troops, as was done in the present war, between Saarlouis and Landau, and advancing, or accepting battle, on the line of road between Mayence and Metz. While the mass of the German troops is stationed there, any French army advancing from Strasbourg into South Germany would be outflanked, and have its communication threatened. If the present campaign has proved anything, it is the facility of invading France from Germany.

But, in good faith, is it not altogether an absurdity and an anachronism to make military considerations the principle by which the boundaries of nations are to be fixed? If this rule were to prevail, Austria would still be entitled to Venetia and the line of the Minicio, and France to the line of the Rhine, in order to protect Paris, which lies certainly more open to an attack from the northeast than Berlin does from the southwest. If limits are to be fixed by military interests, there will be no end to claims, because every military line is necessarily faulty, and may be improved by annexing some more outlying territory; and, moreover, they can never be fixed finally and fairly, because they always must be imposed by the conqueror upon the conquered, and consequently carry within them the seed of fresh wars.

Such is the lesson of all history.

Thus with nations as with individuals. To deprive them of the power of offence, you must deprive them of the means of defence. You must not only garrote, but murder. If every conqueror took "material guarantees" for breaking the sinews of a nation, the first Napoleon did so by the Tilsit Treaty, and the way he executed it against Prussia and the rest of Germany.

Yet, a few years later, his gigantic power split like a rotten reed upon the German people. What are the “material guarantees” Prussia, in her wildest dreams, can or dare impose upon France, compared to the “material guarantees” the first Napoleon had wrenched from herself? The result will not prove the less disastrous. History will measure its retribution, not by the intensity of the square miles conquered from France, but by the intensity of the crime of reviving, in the second half of the 19th century, the policy of conquest!

But, say the mouthpieces of Teutonic patriotism, you must not confound Germans with Frenchmen. What we want is not glory, but safety. The Germans are an essentially peaceful people. In their sober guardianship, conquest itself changes from a condition of future war into a pledge of perpetual peace. Of course, it is not Germans that invaded France in 1792, for the sublime purpose of bayonetting the revolution of the 18th century. It is not Germans that befouled their hands by the subjugation of Italy, the oppressions of Hungary, and the dismemberment of Poland. Their present military system, which divides the whole able-bodied male population into two parts ““ one standing army on service, and another standing army on furlough, both equally bound in passive obedience to rulers by divine right ““ such a military system is, of course, “a material guarantee”, for keeping the peace and the ultimate goal of civilizing tendencies! In Germany, as everywhere else, the sycophants of the powers that be poison the popular mind by the incense of mendacious self-praise.

Indignant as they pretend to be at the sight of French fortresses in Metz and Strasbourg, those German patriots see no harm in the vast system of Moscovite fortifications at Warsaw, Modlin, and Ivangorod. While gloating at the terrors of imperialist invasion, they blink at the infamy of autocratic of autocratic tutelage.

As in 1865, promises were exchanged between Gorchakov and Bismarck. As Louis Bonaparte flattered himself that the War of 1866, resulting in the common exhaustion of Austria and Prussia, would make him the supreme arbiter of Germany, so Alexander flattered himself that the War of 1870, resulting in the common exhaustion of Germany and France, would make him the supreme arbiter of the Western continent. As the Second Empire thought the North German Confederation incompatible with its existence, so autocratic Russia must think herself endangered by a German empire under Prussian leadership. Such is the law of the old

political system. Within its pale the gain of one state is the loss of the other. The tsar's paramount influence over Europe roots in his traditional hold on Germany. At a moment when in Russia herself volcanic social agencies threaten to shake the very base of autocracy, could the tsar afford to bear with such a loss of foreign prestige? Already the Moscovite journals repeat the language of the Bonapartist journals of the War of 1866. Do the Teuton patriots really believe that liberty and peace will be guaranteed to Germany by forcing France into the arms of Russia? If the fortune of her arms, the arrogance of success, and dynastic intrigue lead Germany to a spoilation of French territory, there will then only remain two courses open to her. She must at all risks become the avowed tool of Russian aggrandizement, or, after some short respite, make again ready for another "defensive" war, not one of those new-fangled "localized" wars, but a war of races "“ a war with the Slavonic and Roman races.

The German working class have resolutely supported the war, which it was not in their power to prevent, as a war for German independence and the liberation of France and Europe from that pestilential incubus, the Second Empire. It was the German workmen who, together with the rural laborers, furnished the sinews and muscles of heroic hosts, leaving behind their half-starved families. Decimated by the battles abroad, they will be once more decimated by misery at home. In their turn, they are now coming forward to ask for "guarantees" "“ guarantees that their immense sacrifices have not been bought in vain, that they have conquered liberty, that the victory over the imperialist armies will not, as in 1815, be turned into the defeat of the German people; and, as the first of these guarantees, they claim an honorable peace for France, and the recognition of the French republic.

The Central Committee of the German Social-Democratic Workmen's Party issued, on September 5, a manifesto, energetically insisting upon these guarantees.

"We," they say, "protest against the annexation of Alsace and Lorraine. And we are conscious of speaking in the name of the German working class. In the common interest of France and Germany, in the interest of western civilization against eastern barbarism, the German workmen will not patiently tolerate the annexation of Alsace and Lorraine.... We shall faithfully stand by our fellow workmen in all countries for the common international cause of the proletariat!"

Unfortunately, we cannot feel sanguine of their immediate success. If the French workmen amidst peace failed to stop the aggressor, are the German workmen more likely to stop the victor amidst the clamour of arms? The German workmen's manifesto demands the extradition of Louis Bonaparte as a common felon to the French republic. Their rulers are, on the contrary, already trying hard to restore him to the Tuileries as the best man to ruin France. However that may be, history will prove that the German working class are not made of the same malleable stuff as the German middle class. They will do their duty.

Like them, we hail the advent of the republic in France, but at the same time we labor under misgivings which we hope will prove groundless. That republic has not subverted the throne, but only taken its place, become vacant. It has been proclaimed, not as a social conquest, but as a national measure of defence. It is in the hands of a Provisional Government composed partly of notorious Orleanists, partly of middle class republicans, upon some of whom the insurrection of June 1848 has left its indelible stigma. The division of labor amongst the members of that government looks awkward. The Orleanists have seized the strongholds of the army and the police, while to the professed republicans have fallen the talking departments. Some of their acts go far to show that they have inherited from the empire, not only ruins, but also its dread of the working class. If eventual impossibilities are, in wild phraseology, promised in the name of the republic, is it not with a view to prepare the cry for a "possible" government? Is the republic, by some of its middle class undertakers, not intended to serve as a mere stop-gap and bridge over an Orleanist restoration?

The French working class moves, therefore, under circumstances of extreme difficulty. Any attempt at upsetting the new government in the present crisis, when the enemy is almost knocking at the doors of Paris, would be a desperate folly. The French workmen must perform their duties as citizens; but, at the same time, they must not allow themselves to be swayed by the national souvenirs of 1792, as the French peasant allowed themselves to be deluded by the national souvenirs of the First Empire. They have not to recapitulate the past, but to build up the future. Let them calmly and resolutely improve the opportunities of republican liberty, for the work of their own class organization. It will gift them with fresh herculean powers for the regeneration of France, and our common task ""

the emancipation of labor. Upon their energies and wisdom hinges the fate of the republic.

The English workmen have already taken measures to overcome, by a wholesome pressure from without, the reluctance of their government to recognize the French republic. The present dilatoriness of the British government is probably intended to atone for the Anti-Jacobin war and the former indecent haste in sanctioning the coup d'état. The English workmen call also upon their government to oppose by all its power the dismemberment of France, which a part of the English press is shameless enough to howl for. It is the same press that for 20 years deified Louis Bonaparte as the providence of Europe, that frantically cheered on the slaveholders' rebellion. Now, as then, it drudges for the slaveholder.

Let the sections of the International Working Men's Association in every country stir the working classes to action. If they forsake their duty, if they remain passive, the present tremendous war will be but the harbinger of still deadlier international feuds, and lead in every nation to a renewed triumph over the workman by the lords of the sword, of the soil, and of capital.

Vive la Republique!

France Capitulates & the Government of Thiers

In September 4, 1870, when the working men of Paris proclaimed the republic, which was almost instantaneously acclaimed throughout France, without a single voice of dissent, a cabal of place-hunting barristers, with Thiers for their statesman, and Trochu for their general, took hold of the Hotel de Ville. At that time they were imbued with so fanatical a faith in the mission of Paris to represent France in all epochs of historical crisis that, to legitimate their usurped titles as governors of France, they thought it quite sufficient to produce their lapsed mandates as representatives of Paris.

In our second address on the late war, five days after the rise of these men, we told you who they were. Yet, in the turmoil of surprise, with the real leaders of the working class still shut up in Bonapartist prisons and the Prussians already marching on Paris, Paris bore with their assumption of power, on the express condition that it was to be wielded for the single purpose of national defence. Paris, however, was not to be defended without arming its working class, organizing them into an effective force, and training their ranks by the war itself. But Paris armed was the revolution armed. A victory of Paris over the Prussian aggressor would have been a victory of the French workmen over the French capitalist and his state parasites. In this conflict between national duty and class interest, the Government of National Defence did not hesitate one moment to turn into a Government of National Defection.

The first step they took was to send Thiers on a roving tour to all the courts of Europe, there to beg mediation by offering the barter of the republic for a king. Four months after the commencement of the siege, when they thought the opportune moment came for breaking the first word of capitulation, Trochu, in the presence of Jules Favre, and others of his colleagues, addressed the assembled mayors of Paris in these terms:

“The first question put to me by my colleagues on the very evening of the 4th of September was this: Paris, can it, with any chance of success, stand a siege by the Prussian army? I did not hesitate to answer in the negative. Some of my colleagues here present will warrant the truth of my words and the persistence of my opinion. I told them, in these very terms,

that, under the existing state of things, the attempt of Paris to hold out a siege by the Prussian army would be a folly. Without doubt, I added, it would be an heroic folly; but that would be all.... The events have not given the lie to my prevision."

This nice little speech of Trochu was afterwards published by M. Carbon, one of the mayors present.

Thus, on the very evening of the proclamation of the republic, Trochu's "plan" was known to his colleagues to be the capitulation of Paris. If national defence has been more than a pretext for the personal government of Thiers, Favre, and Co., the upstarts of September 4 would have abdicated on the 5th would have initiated the Paris people into Trochu's "plan", and called upon them to surrender at once, or to take their own fate into their own hands. Instead of this, the infamous impostors resolved upon curing the heroic folly of Paris by a regimen of famine and broken heads, and to dupe her in the meanwhile by ranting manifestos, holding forth that Trochu, "the governor of Paris, will never capitulate", and Jules Favre, the foreign minister, will "not cede an inch of our territory, nor a stone of our fortresses."

In a letter to Gambetta, the very same Jules Favre avows that what they were "defending" against were not the Prussian soldiers, but the working men of Paris. During the whole continuance of the siege, the Bonapartist cut-throats, whom Trochu had wisely intrusted with the command of the Paris army, exchanged, in their intimate correspondence, ribald jokes at the well-understood mockery of defence. (See, for instance, the correspondence of Alphonse Simon Guiod, supreme commander of the artillery of the Army of Defence of Paris and Grand Cross of the Legion of Honor, to Suzanne, general of division of artillery, a correspondence published by the Journal officiel of the Commune.) The mask of the true heroism was at last dropped on January 28, 1871. With the true heroism of utter self-debasement, the Government of National Defence, in their capitulation, came out as the government of France by Bismarck's prisoners a part so base that Louis Bonaparte himself had, at Sedan, shrunk from accepting it. After the events of March 18 on their wild flight to Versailles, the capitulars left in the hands of Paris the documentary evidence of their treason, to destroy which, as the Commune says in its manifesto to the provinces, "those men would not recoil from battering Paris into a heap of ruins washed by a sea of blood."

To be eagerly bent upon such a consummation, some of the leading members of the Government of Defence had, besides, most peculiar reasons of their own.

Shortly after the conclusion of the armistice, M. Milliere, one of the representatives of Paris to the National Assembly, now shot by express orders of Jules Favre, published a series of authentic legal documents in proof that Jules Favre, living in concubinage with the wife of a drunken resident at Algiers, had, by a most daring concoction of forgeries, spread over many years, contrived to grasp, in the name of the children of his adultery, a large succession, which made him a rich man, and that, in a lawsuit undertaken by the legitimate heirs, he only escaped exposure by the connivance of the Bonapartist tribunals. As these dry legal documents were not to be got rid of by any amount of rhetorical horse-power, Jules Favre, for the first time in his life, held his tongue, quietly awaiting the outbreak of the civil war, in order, then, frantically to denounce the people of Paris as a band of escaped convicts in utter revolt against family, religion, order, and property. This same forger had hardly got into power, after September 4, when he sympathetically let loose upon society Pic and Taillefer, convicted, even under the empire, of forgery in the scandalous affair of "Etendard". One of these men, taillefer, having dared to return to Paris under the Commune, was at once reinstated in prison; and then Jules Favre exclaimed, from the tribune of the National Assembly, that Paris was setting free all her jailbirds!

Ernest Picard, the Joe Miller of the Government of National Defence, who appointed himself finance minister of the republic after having in vain striven to become home minister of the empire, is the brother of one Arthur Picard, an individual expelled from the Paris Bourse as a blackleg (see report of the Prefecture of Police, dated July 13, 1867), and convicted, on his own confession, of theft of 300,000 francs, while manager of one of the branches of the Societe Generale, Rue Palestro, No.5 (see report of the Prefecture of Police, dated December 11, 1868). This Arthur Picard was made by Ernest Picard the editor of his paper, l'Electeur Libre. While the common run of stockjobbers were led astray by the official lies of this finance office paper, Arthur was running backwards and forwards between the finance office and the Bourse, there to discount the disasters of the French army. The whole financial correspondence of that worthy pair of brothers fell into the hands of the Commune.

Jules Ferry, a penniless barrister before September 4, contrived, as mayor of Paris during the siege, to job a fortune out of famine. The day on which he would have to give an account of his maladministration would be the day of his conviction.

These men, then, could find in the ruins of Paris only their tickets-of-leave(1); they were the very men Bismarck wanted. With the help of some shuffling of cards, Thiers, hitherto the secret prompter of the government, now appeared at its head, with the tickets-of-leave men for his ministers.

Thiers, that monstrous gnome, has charmed the French bourgeoisie for almost half a century, because he is the most consummate intellectual expression of their own class corruption. Before he became a statesman, he had already proved his lying powers as an historian. The chronicle of his public life is the record of the misfortunes of France. Banded, before 1830, with the republicans, he slipped into office under Louis Philippe by betraying his protector Lafitte, ingratiating himself with the king by exciting mob riots against the clergy, during which the church of Saint Germain l'Auxerrois and the Archbishop's palace were plundered, and by acting the minster-spy upon, and the jail-accoucheur of the Duchess de Berry. The massacre of the republicans in the Rue Transnonian, and the subsequent infamous laws of September against the press and the right of association, were his work. Reappearing as the chief of the cabinet in March 1840, he astonished France with his plan for fortifying France. To the republicans, who denounced this plan as a sinister plot against the liberty of Paris, he replied from the tribune of the Chamber of Deputies:

“What! to fancy that any works of fortification could ever endanger liberty! And first of all you calumniate any possible government in supposing that it could some day attempt to maintain itself by bombarding the capital; but that the government would be a hundred times more impossible after its victory than before.”

Indeed, no government would ever have dared to bombard Paris from the forts, save that government which had previously surrendered these forts to the Prussians.

When King Bomba tried his hand at Palermo, in January 1848, Thiers, then long since out of office, again rose in the Chamber of Deputies:

“You know, gentlemen, what is happening at Palermo. You, all of you, shake with horror on hearing that during 48 hours a large town has been bombarded by whom? Was it a foreign enemy exercising the rights of war?

No, gentlemen, it was by its own government. And why? Because the unfortunate town demanded its right. Well, then, for the demand of its rights it has got 48 hours of bombardment.... Allow me to appeal to the opinion of Europe. It is doing a service to mankind to arise, and to make reverberate, from what is perhaps the greatest tribune in Europe, some words of indignation against such acts.... When the Regent Espartero, who had rendered services to his country intended bombarding Barcelona, in order to suppress its insurrection, there arose from all parts of the world a general outcry of indignation.”

Eighteen months afterwards, M. Thiers was amongst the fiercest defenders of the bombardment of Rome by a French army. In fact, the fault of King Bomba seems to have consisted in this only that he limited his bombardment to 48 hours.

A few days before the February Revolution, fretting at the long exile from place and pelf to which Guizot had condemned him, and sniffing in the air the scent of an approaching popular commotion, Thiers, in that pseudo-heroic style which won him the nickname *Mirabeau-mouche*, declared, to the Chamber of Deputies:

“I am of the party of revolution, not only in France, but in Europe. I wish the government of the revolution to remain in the hands of moderate men... but if that government should fall into the hand of ardent minds, even into those of radicals, I shall, for all that, not desert my cause. I shall always be of the party of the revolution.”

The February Revolution came. Instead of displacing the Guizot Cabinet by the Thiers Cabinet, as the little man had dreamt, it superseded Louis Philippe by the republic. On the first day of the popular victory, he carefully hid himself, forgetting that the contempt of the working men screened him from their hatred. Still, with his legendary courage, he continued to shy the public stage, until the June massacres had cleared it for his sort of action. Then he became the leading mind of the “Party of Order” and its parliamentary republic, that anonymous interregnum, in which all the rival factions of the ruling class conspired together to crush the people, and conspired against each other to restore to each of them its own monarchy. Then, as now, Thiers denounced the republicans as the only obstacle to the consolidation of the republic; then, as now, he spoke to the republic as the hangman spoke to Don Carlos: “I shall assassinate thee, but for thy own

good.” Now, as then, he will have to exclaim on the day after his victory: L’Empire est fait the empire is consummated.

Despite his hypocritical homilies about the necessary liberties and his personal grudge against Louis Bonaparte, who had made a dupe of him, and kicked out parliamentarism and, outside of its factitious atmosphere, the little man is conscious of withering into nothingness he had a hand in all the infamies of the Second Empire, from the occupation of Rome by French troops to the war with Prussia, which he incited by his fierce invective against German unity not as a cloak of prussian despotism, but as an encroachment upon the vested right of France in German disunion. Fond of brandishing, with his dwarfish arms in the face of Europe, the sword of the first Napoleon, whose historical shoeblack he had become, his foreign policy always culminated in the utter humiliation of France from the London convention of 1840 to the Paris capitulation of 1871, and the present civil war, where he hounds on the prisoners of Sedan and Metz against Paris by special permission of Bismarck.

Despite his versatility of talent and shiftiness of purpose, this man has his whole lifetime been wedded to the most fossil routine. It is self-evident that to him the deeper undercurrents of modern society remained forever hidden; but even the most palpable changes on its surface were abhorrent to a brain (all the vitality of which) had fled to the tongue. Thus, he never tired of denouncing as a sacrilege any deviation from the old French protective system.

When a minister of Louis Philippe, he railed at railways as a wild chimera; and when in opposition under Louis Bonaparte, he branded as a profanation every attempt to reform the rotten French army system. Never in his long political career has he been guilty of a single even the smallest measure of any practical use. Theirs was consistent only in his greed for wealth and his hatred of the men that produce it. Having entered his first ministry, under Louis Philippe, poor as Job, he left it a millionaire. His last ministry under the same king (of March 1, 1840) exposed him to public taunts of peculation in the Chamber of Deputies, to which he was content to reply by tears a commodity he deals in as freely as Jules favre, or any other crocodile. At Bordeaux, his first measure for saving France from impending financial ruin was to endow himself with three millions a year, the first and the last word of the “Economical Republic”, the vista of which he had opened to his Paris electors in 1869. One of his former colleagues of the

Chamber of Deputies of 1830, himself a capitalist and, nevertheless, a devoted member of the Paris Commune, M. Beslay, lately addressed Thiers thus in a public placard:

“The enslavement of labor by capital has always been the cornerstone of your policy, and from the very day you saw the Republic of Labor installed at the Hotel de Ville, you have never ceased to cry out to France: ‘These are criminals!’”

A master in small state roguery, a virtuoso in perjury and treason, a craftsman in all the petty stratagems, cunning devices, and base perfidies of parliamentary warfare; never scrupling, when out of office, to fan a revolution, and to stifle it in blood when at the helm of the state; with class prejudices standing him in the place of ideas, and vanity in the place of a heart; his private life as infamous as his public life is odious even now, when playing the part of a French Sulla, he cannot help setting off the abomination of his deeds by the ridicule of his ostentation.

The capitulation of Paris, by surrendering to Prussia not only Paris, but all France, closed the long-continued intrigues of treason with the enemy, which the usurpers of September 4 had begun, as Trochu himself said, on the very same day. On the other hand, it initiated the civil war they were now to wage, with the assistance of Prussia, against the Republic and Paris. The trap was laid in the very terms of the capitulation. At that time, above one-third of the territory was in the hands of the enemy, the capital was cut off from the provinces, all communications were disorganized. To elect, under such circumstances, a real representation of France was impossible, unless ample time were given for preparation. In view of this, the capitulation stipulated that a National Assembly must be elected within eight days; so that in many parts of France the news of the impending election arrived on its eve only. This assembly, moreover, was, by an express clause of the capitulation, to be elected for the sole purpose of deciding on peace or war, and, eventually, to conclude a treaty of peace. The population could not but feel that the terms of the armistice rendered the continuation of the war impossible, and that for sanctioning the peace imposed by Bismarck, the worst men in France were the best. But not content with these precautions, Thiers even before the secret of the armistice had been broached to Paris, set out for an electioneering tour through the provinces, there to galvanize back into life the Legitimist party, which now, along with the Orleanists, had to take the place of the then

impossible Bonapartists. He was not afraid of them. Impossible as a government of modern France, and, therefore, contemptible as rivals, what party were more eligible as tools of counter-revolution than the party whose action, in the words of Thiers himself (Chamber of Deputies, January 5, 1833), “Had always been confined to the three resources of foreign invasion, civil war, and anarchy”? They verily believed in the advent of their long-expected retrospective millenium. There were the heels of foreign invasion trampling upon France; there was the downfall of an empire, and the captivity of Bonaparte; and there they were themselves. The wheel of history had evidently rolled back to stop at the “Chambers introuvable” of 1816. In the assemblies of the republic, 1848 to 1851. They had been represented by their educated and trained parliamentary champions it was the rank-and-file of the party which now rushed in all the Pourceaugnacs of France.

As soon as this Assembly of “Rurals” had met at Bordeaux, Thiers made it clear to them that the peace preliminaries must be assented to at once, without even the honors of a parliamentary debate, as the only conditions on which Prussia would permit them to open the war against the republic and Paris, its stronghold. The counter-revolution had, in fact, no time to lose. The Second Empire had more than doubled the national debt, and plunged all the large towns into heavy municipal debts. The war had fearfully swelled the liabilities, and mercilessly ravaged the resources of the nation. To complete the ruin, the Prussian Shylock was there with his bond for the keep of half a million of his soldiers on French soil, his indemnity for five milliards, and interest at 5 per cent on the unpaid instalments thereof. Who was to pay this bill? It was only by the violent overthrow of the republic that the appropriators of wealth could hope to shift onto the shoulders of its producers the cost of a war which they, the appropriators, had themselves originated. Thus, the immense ruin of France spurred on these patriotic representatives of land and capital, under the very eyes and patronage of the invader, to graft upon the foreign war a civil war a slaveholders’ rebellion.

There stood in the way of this conspiracy one great obstacle Paris. To disarm Paris was the first condition of success. Paris was therefore summoned by Thiers to surrender its arms. Then Paris was exasperated by the frantic anti-republican demonstrations of the “Rural” Assembly and by Thiers’ own equivocations about the legal status of the republic; by the

threat to decapitate and decapitalize Paris; the appointment of Orleanist ambassadors; Dufaure's laws on over-due commercial bills and house rents, inflicting ruin on the commerce and industry of Paris; Pouyer-Quertier's tax of two centimes upon every copy of every imaginable publication; the sentences of death against Blanqui and Flourens; the suppression of the republican journals; the transfer of the National Assembly to Versailles; the renewal of the state of siege declared by Palikao, and expired on September 4; the appointment of Vinoy, the De'cembreur, as governor of Paris of Valentin, the imperialist gendarme, as its prefect of police and of D'Aurelles de Paladine, the Jesuit general, as the commander-in-chief of its National Guard.

And now we have to address a question to M. Thiers and the men of national defence, his under-strappers. It is known that, through the agency of M. Pouyer-Quertier, his finance ministers, Thiers had contracted a loan of two milliards. Now, is it true or not

1. That the business was so managed that a consideration of several hundred millions was secured for the private benefit of Thiers, Jules Favre, Ernest Picard, Pouyer-Quertier, and Jules Simon? and

2. That no money was to be paid down until after the "pacification" of Paris?

At all events, there must have been something very pressing in the matter, for Thiers and Jules Favre, in the name of the majority of the Bordeaux Assembly, unblushingly solicited the immediate occupation of Paris by Prussian troops. Such, however, was not the game of Bismarck, as he sneeringly, and in public, told the admiring Frankfort philistines on his return to Germany.

Paris Workers' Revolution & Thiers' Reactionary Massacres

Armed Paris was the only serious obstacle in the way of the counter-revolutionary conspiracy. Paris was, therefore, to be disarmed.

On this point, the Bordeaux Assembly was sincerity itself. If the roaring rant of its Rurals had not been audible enough, the surrender of Paris by Thiers to the tender mercies of the triumvirate of Vinoy the Decembriseur, Valentin the Bonapartist gendarme, and Aurelles de Paladine the Jesuit general, would have cut off even the last subterfuge of doubt.

But while insultingly exhibiting the true purpose of the disarmament of Paris, the conspirators asked her to lay down her arms on a pretext which was the most glaring, the most barefaced of lies. The artillery of the Paris National Guard, said Thiers, belonged to the state, and to the state it must be returned. The fact was this: From the very day of the capitulation, by which Bismarck's prisoners had signed the surrender of France, but reserved to themselves a numerous bodyguard for the express purpose of cowing Paris, Paris stood on the watch. The National Guard reorganized themselves and intrusted their supreme control to a Central Committee elected by their whole body, save some fragments of the old Bonapartist formations. On the eve of the entrance of the Prussians into Paris, the Central Committee took measures for the removal to Montmartre, Belleville, and La Villette, of the cannon and mitrailleuses treacherously abandoned by the capitulars in and about the very quarters the Prussians were to occupy. That artillery had been furnished by the subscriptions of the National Guard. As their private property, it was officially recognized in the capitulation of January 28, and on that very title exempted from the general surrender, into the hands of the conqueror, or arms belonging to the government. And Thiers was so utterly destitute of even the flimsiest pretext for initiating the war against Paris, that he had to resort to the flagrant lie of the artillery of the National Guard being state property!

The seizure of her artillery was evidently but to serve as the preliminary to the general disarmament of Paris, and, therefore, of the Revolution of September 4. But that revolution had become the legal status of France. The republic, its work, was recognized by the conqueror in the terms of the

capitulation. After the capitulation, it was acknowledged by all foreign powers, and in its name, the National Assembly had been summoned. The Paris working men's revolution of September 4 was the only legal title of the National Assembly seated at Bordeaux, and of its executive. Without it, the National Assembly would at once have to give way to the Corps Legislatif elected in 1869 by universal suffrage under French, not under Prussian, rule, and forcibly dispersed by the arm of the revolution. Thiers and his ticket-of-leave men would have had to capitulate for safe conducts signed by Louis Bonaparte, to save them from a voyage to Cayenne, The National Assembly, with its power of attorney to settle the terms of peace with Prussia, was but an incident of that revolution, the true embodiment of which was still armed Paris, which had initiated it, undergone for it a five-months' siege, with its horrors of famine, and made her prolonged resistance, despite Trochu's plan, the basis of an obstinate war of defence in the provinces. And Paris was now either to lay down her arms at the insulting behest of the rebellious slaveholders of Bordeaux, and acknowledge that her Revolution of September 4 meant nothing but a simple transfer of power from Louis Bonaparte to his royal rivals; or she had to stand forward as the self-sacrificing champion of France, whose salvation from ruin and who regeneration were impossible without the revolutionary overthrow of the political and social conditions that had engendered the Second Empire, and under its fostering care, matured into utter rottenness. Paris, emaciated by a five-months' famine, did not hesitate one moment. She heroically resolved to run all the hazards of a resistance against French conspirators, even with Prussian cannon frowning upon her from her own forts. Still, in its abhorrence of the civil war into which Paris was to be goaded, the Central Committee continued to persist in a merely defensive attitude, despite the provocations of the Assembly, the usurpations of the Executive, and the menacing concentration of troops in and around Paris.

Thiers opened the civil war by sending Vinoy, at the head of a multitude of sergents-de-ville, and some regiments of the line, upon a nocturnal expedition against Montmartre, there to seize, by surprise, the artillery of the National Guard. It is well known how this attempt broke down before the resistance of the National Guard and the fraternization of the line with the people. Aurelles de Paldine had printed beforehand his bulletin of victory, and Thiers held ready the placards announcing his measures of

coup d'etat. Now these had to be replaced by Thiers' appeals, imparting his magnanimous resolve to leave the National Guard in the possession of their arms, with which, he said, he felt sure they would rally round the government against the rebels. Out of 300,000 National guards, only 300 responded to this summons to rally around little Thiers against themselves. The glorious working men's Revolution of March 18 took undisputed sway of Paris. The Central Committee was its provisional government. Europe seemed, for a moment, to doubt whether its recent sensational performances of state and war had any reality in them, or whether they were the dreams of a long bygone past.

From March 18 to the entrance of the Versailles troops into Paris, the proletarian revolution remained so free from the acts of violence in which the revolutions "" and still more the counter-revolutions "" of the "better classes" abound, that no facts were left to its opponents to cry out about, but the executions of Generals Lecomte and Clement Thomas, and the affair of the Place Vendome.

One of the Bonapartist officers engaged in the nocturnal attempt against Montmartre, General Lecomte, had four times ordered the 81st line regiment to fire at an unarmed gathering in the Place Pigalle, and on their refusal fiercely insulted them. Instead of shooting women and children, his own men shot him. The inveterate habits acquired by the soldiery under the training of the enemies of the working class are, of course, not likely to change the very moment these soldiers change sides. The same men executed Clement Thomas.

"General" Clement Thomas, a malcontent ex-quartermaster-sergeant, had, in the latter times of Louis Philippe's reign, enlisted at the office of the republican newspaper Le National, there to serve in the double capacity of responsible man-of-straw (gerant responsable) and of duelling bully to that very combative journal. After the February Revolution, the men of the National having got into power, they metamorphosed this old quartermaster-sergeant into a general on the eve of the butchery of June "" of which he, like Jules Favre, was one of the sinister plotters, and became one of the most dastardly executioners. Then he and his generalship disappeared for a long time, to again rise to the surface on November 1, 1870. The day before, the Government of National Defence, caught at the Hotel de Ville, had solemnly pledged their parole to Blanqui, Flourens, and other representatives of the working class, to abdicate their usurped power into

the hands of a commune to be freely elected by Paris. Instead of keeping their word, they let loose on Paris the Bretons of Trochu, who now replaced the Corsicans of Bonaparte. General Tamisier alone, refusing to sully his name by such a breach of faith, resigned the commandership-in-chief of the National Guard, and in his place Clement Thomas for once became again a general. During the whole of his tenure of command, he made war, not upon the Prussians, but upon the Paris National Guard. He prevented their general armament, pitted the bourgeois battalions against the working men's battalions, weeded out officers hostile to Trochu's "plan", and disbanded, under the stigma of cowardice, the very same proletarian battalions whose heroism has now astonished their most inveterate enemies. Clement Thomas felt quite proud of having reconquered his June pre-eminence as the personal enemy of the working class of Paris. Only a few days before March 18, he laid before the War Minister, Leflo, a plan of his own for "finishing off la fine fleur of the Paris canaille". After Vinoy's rout, he must needs appear upon the scene of action in the quality of an amateur spy. The Central Committee and the Paris working men were as much responsible for the killing of Clement Thomas and Lecomte as the Princess of Wales for the fate of the people crushed to death on the day of her entrance into London.

The massacre of unarmed citizens in Place Vendome is a myth which M. Thiers and the Rurals persistently ignored in the Assembly, entrusting its propagation exclusively to the servants' hall of European journalism. "The men of order", the reactionists of Paris, trembled at the victory of March 18. To them, it was the signal of popular retribution at last arriving. The ghosts of the victims assassinated at their hands from the days of June 1848, down to January 22, 1871, arose before their faces. Their panic was their only punishment. Even the sergents-de-ville, instead of being disarmed and locked up, as ought to have been done, had the gates of Paris flung open wide for their safe retreat to Versailles. The men of order were left not only unharmed, but allowed to rally and quietly seize more than one strong hold in the very centre of Paris. This indulgence of the Central Committee "" this magnanimity of the armed working men "" so strangely at variance with the habits of the "Party of Order", the latter misinterpreted as mere symptoms of conscious weakness. Hence their silly plan to try, under the cloak of an unarmed demonstration, what Vinoy had failed to perform with his cannon and mitrailleuses. On March 22, a riotous mob of swells started from the

quarters of luxury, all the petits creves in their ranks, and at their head the notorious familiars of the empire ““ the Heeckeren, Coetlogon, Henri de Pene, etc. Under the cowardly pretence of a pacific demonstration, this rabble, secretly armed with the weapons of the bravo, fell into marching order, ill-treated and disarmed the detached patrols and sentries of the National Guard they met with on their progress, and, on debouching from the Rue de la Paix, with the cry of “Down with the Central Committee! Down with the assassins! The National Assembly forever!” attempted to break through the line drawn up there, and thus to carry by surprise the headquarters of the National Guard in the Place Vendome. In reply to their pistol-shots, the regular sommations (the French equivalent of the English Riot Act) were made, and, proving ineffective, fire was commanded by the general of the National Guard. One volley dispersed into wild flight the silly coxcombs, who expected that the mere exhibition of their “respectability” would have the same effect upon the Revolution of Paris as Joshua’s trumpets upon the walls of Jericho. The runaways left behind them two National Guards killed, nine severely wounded (among them a member of the Central Committee), and the whole scene of their exploit strewn with revolvers, daggers, and sword-canes, in evidence of the “unarmed” character of their “pacific” demonstration. When, on June 13, 1849, the National Guard made a really pacific demonstration in protest against the felonious assault of French troops upon Rome, Changarnier, then general of the Party of Order, was acclaimed by the National Assembly, and especially by M. Thiers, as the savior of society, for having launched his troops from all sides upon these unarmed men, to shoot and sabre them down, and to trample them under their horses’ feet. Paris, then was placed under a state of siege. Dufaure hurried through the Assembly new laws of repression. New arrests, new proscriptions ““ a new reign of terror set in. But the lower orders manage these things otherwise. The Central Committee of 1871 simply ignored the heroes of the “pacific demonstration”; so much so, that only two days later, they were enabled to muster under Admiral Saisset, for that armed demonstration, crowned by the famous stampede to Versailles. In their reluctance to continue the civil war opened by Thiers’ burglarious attempt on Montmartre, the Central Committee made themselves, this time, guilty of a decisive mistake in not at once marching upon Versailles, then completely helpless, and thus putting an end to the conspiracies of Thiers and his Rurals. Instead of this, the Party of Order was again allowed to try

its strength at the ballot box, on March 26. The day of the election of the Commune. Then, in the mairies of Paris, they exchanged land words of conciliation with their too generous conquerors, muttering in their hearts solemn vows to exterminate them in due time.

Now, look at the reverse of the medal. Thiers opened his second campaign against Paris in the beginning of April. The first batch of Parisian prisoners brought into Versailles was subjected to revolting atrocities, while Ernest Picard, with his hands in his trousers' pockets, strolled about jeering them, and while Mesdames Thiers and Favre, in the midst of their ladies of honor applauded, from the balcony, the outrages of the Versailles mob. The captured soldiers of the line were massacred in cold blood; our brave friend, General Duval, the iron-founder, was shot without any form of trial. Galifet, the kept man of his wife, so notorious for her shameless exhibitions at the orgies of the Second Empire, boasted in a proclamation of having commanded the murder of a small troop of national Guards, with their captain and lieutenant, surprised and disarmed by his Chasseurs. Vinoy, the runaway, was appointed by Thiers, Grand Cross of the Legion of Honor, for his general order to shoot down every soldier of the line taken in the ranks of the Federals. Desmaret, the Gendarme, was decorated for the treacherous butcher-like chopping in pieces of the high-souled and chivalrous Flourens, who had saved the heads of the Government of Defence on October 31, 1870. "The encouraging particulars" of his assassination were triumphantly expatiated upon by Thiers in the National Assembly. With the elated vanity of a parliamentary Tom Thumb permitted to play the part of a Tamerlane, he denied the rebels the right of neutrality for ambulances. Nothing more horrid than that monkey allowed for a time to give full fling to his tigerish instincts, as foreseen by Voltaire.

After the decree of the Commune of April 7, ordering reprisals and declaring it to be the duty "to protect Paris against the cannibal exploits of the Versailles banditti, and to demand an eye for an eye, a tooth for a tooth", Thiers did not stop the barbarous treatment of prisoners, moreover, insulting them in his bulletins as follows: "Never have more degraded countenances of a degraded democracy met the afflicted gazes of honest men" "honest, like Thiers himself and his ministerial ticket-of-leave men. Still, the shooting of prisoners was suspended for a time. Hardly, however, had Thiers and his Decembrist generals become aware that the Communal decree of reprisals was but an empty threat, that even their gendarme spies caught in Paris

under the disguise of National Guards, that even sergents-de-ville, taken with incendiary shells upon them, were spared ““ when the wholesale shooting of prisoners was resumed and carried on uninterruptedly to the end. houses to which National Guards had fled were surrounded by gendarmes, inundated with petroleum (which here occurs for the first time in this war), and then set fire to, the charred corpses being afterwards brought out by the ambulance of the Press at the Ternes. Four National Guards having surrendered to a troop of mounted Chasseurs at Belle Epine, on April 25, were afterwards shot down, one after another, by the captain, a worthy man of Gallifet's. One of his four victims, left for dead, Scheffer, crawled back to the Parisian outposts, and deposed to this fact before a commission of the Commune. When Tolain interpellated the War Minister upon the report of this commission, the Rurals drowned his voice and forbade Leflo to answer. It would be an insult to their “glorious” army to speak of its deeds. The flippant tone in which Thiers’ bulletin announced the bayoneting of the Federals, surprised asleep at Moulin Saquet, and the wholesale fusillades at Clamart shocked the nerves even of the not over-sensitive London Times. But it would be ludicrous today to attempt recounting the merely preliminary atrocities committed by the bombardiers of Paris and the fomenters of a slaveholders’ rebellion protected by foreign invasion. Amidst all these horrors, Thiers, forgetful of his parliamentary laments on the terrible responsibility weighing down his dwarfish shoulders, boasts in his bulletins that l’Assemblée siege paisiblement (the Assembly continues meeting in peace), and proves by his constant carousals, now with Decembrist generals, now with German princes, that his digestion is not troubled in the least, not even by the ghosts of Lecomte and Clement Thomas.

The Paris Commune

On the dawn of March 18, Paris arose to the thunder-burst of “Vive la Commune!” What is the Commune, that sphinx so tantalizing to the bourgeois mind?

“The proletarians of Paris,” said the Central Committee in its manifesto of March 18, “amidst the failures and treasons of the ruling classes, have understood that the hour has struck for them to save the situation by taking into their own hands the direction of public affairs.... They have understood that it is their imperious duty, and their absolute right, to render themselves masters of their own destinies, by seizing upon the governmental power.”

But the working class cannot simply lay hold of the ready-made state machinery, and wield it for its own purposes.

The centralized state power, with its ubiquitous organs of standing army, police, bureaucracy, clergy, and judicature organs wrought after the plan of a systematic and hierarchic division of labor originates from the days of absolute monarchy, serving nascent middle class society as a mighty weapon in its struggle against feudalism. Still, its development remained clogged by all manner of medieval rubbish, seignorial rights, local privileges, municipal and guild monopolies, and provincial constitutions. The gigantic broom of the French Revolution of the 18th century swept away all these relics of bygone times, thus clearing simultaneously the social soil of its last hinderances to the superstructure of the modern state edifice raised under the First Empire, itself the offspring of the coalition wars of old semi-feudal Europe against modern France.

During the subsequent regimes, the government, placed under parliamentary control that is, under the direct control of the propertied classes became not only a hotbed of huge national debts and crushing taxes; with its irresistible allurements of place, pelf, and patronage, it became not only the bone of contention between the rival factions and adventurers of the ruling classes; but its political character changed simultaneously with the economic changes of society. At the same pace at which the progress of modern industry developed, widened, intensified the class antagonism between capital and labor, the state power assumed more and more the

character of the national power of capital over labor, of a public force organized for social enslavement, of an engine of class despotism.

After every revolution marking a progressive phase in the class struggle, the purely repressive character of the state power stands out in bolder and bolder relief. The Revolution of 1830, resulting in the transfer of government from the landlords to the capitalists, transferred it from the more remote to the more direct antagonists of the working men. The bourgeois republicans, who, in the name of the February Revolution, took the state power, used it for the June massacres, in order to convince the working class that “social” republic means the republic entrusting their social subjection, and in order to convince the royalist bulk of the bourgeois and landlord class that they might safely leave the cares and emoluments of government to the bourgeois “republicans”.

However, after their one heroic exploit of June, the bourgeois republicans had, from the front, to fall back to the rear of the “Party of Order” a combination formed by all the rival fractions and factions of the appropriating classes. The proper form of their joint-stock government was the parliamentary republic, with Louis Bonaparte for its president. Theirs was a regime of avowed class terrorism and deliberate insult towards the “vile multitude”.

If the parliamentary republic, as M. Thiers said, “divided them least”, it opened an abyss between that class and the whole body of society outside their spare ranks. The restraints by which their own divisions had under former regimes still checked the state power, were removed by their union; and in view of the threatening upheaval of the proletariat, they now used that state power mercilessly and ostentatiously as the national war engine of capital against labor.

In their uninterrupted crusade against the producing masses, they were, however, bound not only to invest the executive with continually increased powers of repression, but at the same time to divest their own parliamentary stronghold the National Assembly one by one, of all its own means of defence against the Executive. The Executive, in the person of Louis Bonaparte, turned them out. The natural offspring of the “Party of Order” republic was the Second Empire.

The empire, with the coup d’etat for its birth certificate, universal suffrage for its sanction, and the sword for its sceptre, professed to rest upon the peasantry, the large mass of producers not directly involved in the

struggle of capital and labor. It professed to save the working class by breaking down parliamentarism, and, with it, the undisguised subserviency of government to the propertied classes. It professed to save the propertied classes by upholding their economic supremacy over the working class; and, finally, it professed to unite all classes by reviving for all the chimera of national glory.

In reality, it was the only form of government possible at a time when the bourgeoisie had already lost, and the working class had not yet acquired, the faculty of ruling the nation. It was acclaimed throughout the world as the savior of society. Under its sway, bourgeois society, freed from political cares, attained a development unexpected even by itself. Its industry and commerce expanded to colossal dimensions; financial swindling celebrated cosmopolitan orgies; the misery of the masses was set off by a shameless display of gorgeous, meretricious and debased luxury. The state power, apparently soaring high above society and the very hotbed of all its corruptions. Its own rottenness, and the rottenness of the society it had saved, were laid bare by the bayonet of Prussia, herself eagerly bent upon transferring the supreme seat of that regime from Paris to Berlin. Imperialism is, at the same time, the most prostitute and the ultimate form of the state power which nascent middle class society had commenced to elaborate as a means of its own emancipation from feudalism, and which full-grown bourgeois society had finally transformed into a means for the enslavement of labor by capital.

The direct antithesis to the empire was the Commune. The cry of “social republic”, with which the February Revolution was ushered in by the Paris proletariat, did but express a vague aspiration after a republic that was not only to supercede the monarchical form of class rule, but class rule itself. The Commune was the positive form of that republic.

Paris, the central seat of the old governmental power, and, at the same time, the social stronghold of the French working class, had risen in arms against the attempt of Thiers and the Rurals to restore and perpetuate that old governmental power bequeathed to them by the empire. Paris could resist only because, in consequence of the siege, it had got rid of the army, and replaced it by a National Guard, the bulk of which consisted of working men. This fact was now to be transformed into an institution. The first decree of the Commune, therefore, was the suppression of the standing army, and the substitution for it of the armed people.

The Commune was formed of the municipal councillors, chosen by universal suffrage in the various wards of the town, responsible and revocable at short terms. The majority of its members were naturally working men, or acknowledged representatives of the working class. The Commune was to be a working, not a parliamentary body, executive and legislative at the same time.

Instead of continuing to be the agent of the Central Government, the police was at once stripped of its political attributes, and turned into the responsible, and at all times revocable, agent of the Commune. So were the officials of all other branches of the administration. From the members of the Commune downwards, the public service had to be done at workman's wage. The vested interests and the representation allowances of the high dignitaries of state disappeared along with the high dignitaries themselves. Public functions ceased to be the private property of the tools of the Central Government. Not only municipal administration, but the whole initiative hitherto exercised by the state was laid into the hands of the Commune.

Having once got rid of the standing army and the police the physical force elements of the old government the Commune was anxious to break the spiritual force of repression, the "parson-power", by the disestablishment and disendowment of all churches as proprietary bodies. The priests were sent back to the recesses of private life, there to feed upon the alms of the faithful in imitation of their predecessors, the apostles.

The whole of the educational institutions were opened to the people gratuitously, and at the same time cleared of all interference of church and state. Thus, not only was education made accessible to all, but science itself freed from the fetters which class prejudice and governmental force had imposed upon it.

The judicial functionaries were to be divested of that sham independence which had but served to mask their abject subserviency to all succeeding governments to which, in turn, they had taken, and broken, the oaths of allegiance. Like the rest of public servants, magistrates and judges were to be elective, responsible, and revocable.

The Paris Commune was, of course, to serve as a model to all the great industrial centres of France. The communal regime once established in Paris and the secondary centres, the old centralized government would in the provinces, too, have to give way to the self-government of the producers.

In a rough sketch of national organization, which the Commune had no time to develop, it states clearly that the Commune was to be the political form of even the smallest country hamlet, and that in the rural districts the standing army was to be replaced by a national militia, with an extremely short term of service. The rural communities of every district were to administer their common affairs by an assembly of delegates in the central town, and these district assemblies were again to send deputies to the National Delegation in Paris, each delegate to be at any time revocable and bound by the mandat impératif (formal instructions) of his constituents. The few but important functions which would still remain for a central government were not to be suppressed, as has been intentionally misstated, but were to be discharged by Communal and thereafter responsible agents.

The unity of the nation was not to be broken, but, on the contrary, to be organized by Communal Constitution, and to become a reality by the destruction of the state power which claimed to be the embodiment of that unity independent of, and superior to, the nation itself, from which it was but a parasitic excrescence.

While the merely repressive organs of the old governmental power were to be amputated, its legitimate functions were to be wrested from an authority usurping pre-eminence over society itself, and restored to the responsible agents of society. Instead of deciding once in three or six years which member of the ruling class was to misrepresent the people in Parliament, universal suffrage was to serve the people, constituted in Communes, as individual suffrage serves every other employer in the search for the workmen and managers in his business. And it is well-known that companies, like individuals, in matters of real business generally know how to put the right man in the right place, and, if they for once make a mistake, to redress it promptly. On the other hand, nothing could be more foreign to the spirit of the Commune than to supercede universal suffrage by hierarchical investiture.

It is generally the fate of completely new historical creations to be mistaken for the counterparts of older, and even defunct, forms of social life, to which they may bear a certain likeness. Thus, this new Commune, which breaks with the modern state power, has been mistaken for a reproduction of the medieval Communes, which first preceded, and afterward became the substratum of, that very state power. The Communal Constitution has been mistaken for an attempt to break up into the

federation of small states, as dreamt of by Montesquieu and the Girondins, that unity of great nations which, if originally brought about by political force, has now become a powerful coefficient of social production. The antagonism of the Commune against the state power has been mistaken for an exaggerated form of the ancient struggle against over-centralization. Peculiar historical circumstances may have prevented the classical development, as in France, of the bourgeois form of government, and may have allowed, as in England, to complete the great central state organs by corrupt vestries, jobbing councillors, and ferocious poor-law guardians in the towns, and virtually hereditary magistrates in the counties.

The Communal Constitution would have restored to the social body all the forces hitherto absorbed by the state parasite feeding upon, and clogging the free movement of, society. By this one act, it would have initiated the regeneration of France.

The provincial French middle class saw in the Commune an attempt to restore the sway their order had held over the country under Louis Philippe, and which, under Louis Napoleon, was supplanted by the pretended rule of the country over the towns. In reality, the Communal Constitution brought the rural producers under the intellectual lead of the central towns of their districts, and there secured to them, in the working men, the natural trustees of their interests. The very existence of the Commune involved, as a matter of course, local municipal liberty, but no longer as a check upon the now superseded state power. It could only enter into the head of a Bismarck who, when not engaged on his intrigues of blood and iron, always likes to resume his old trade, so befitting his mental calibre, of contributor to *Kladderadatsch* (the Berlin Punch) it could only enter into such a head to ascribe to the Paris Commune aspirations after the caricature of the old French municipal organization of 1791, the Prussian municipal constitution which degrades the town governments to mere secondary wheels in the police machinery of the Prussian state. The Commune made that catchword of bourgeois revolutions cheap government a reality by destroying the two greatest sources of expenditure: the standing army and state functionarism. Its very existence presupposed the non-existence of monarchy, which, in Europe at least, is the normal incumbrance and indispensable cloak of class rule. It supplied the republic with the basis of really democratic institutions. But neither cheap government nor the "true republic" was its ultimate aim; they were its mere concomitants.

The multiplicity of interpretations to which the Commune has been subjected, and the multiplicity of interests which construed it in their favor, show that it was a thoroughly expansive political form, while all the previous forms of government had been emphatically repressive. Its true secret was this:

It was essentially a working class government, the product of the struggle of the producing against the appropriating class, the political form at last discovered under which to work out the economical emancipation of labor.

Except on this last condition, the Communal Constitution would have been an impossibility and a delusion. The political rule of the producer cannot co-exist with the perpetuation of his social slavery. The Commune was therefore to serve as a lever for uprooting the economical foundation upon which rests the existence of classes, and therefore of class rule. With labor emancipated, every man becomes a working man, and productive labor ceases to be a class attribute.

It is a strange fact. In spite of all the tall talk and all the immense literature, for the last 60 years, about emancipation of labor, no sooner do the working men anywhere take the subject into their own hands with a will, than uprises at once all the apologetic phraseology of the mouthpieces of present society with its two poles of capital and wages-slavery (the landlord now is but the sleeping partner of the capitalist), as if the capitalist society was still in its purest state of virgin innocence, with its antagonisms still undeveloped, with its delusions still unexploded, with its prostitute realities not yet laid bare. The Commune, they exclaim, intends to abolish property, the basis of all civilization!

Yes, gentlemen, the Commune intended to abolish that class property which makes the labor of the many the wealth of the few. It aimed at the expropriation of the expropriators. It wanted to make individual property a truth by transforming the means of production, land, and capital, now chiefly the means of enslaving and exploiting labor, into mere instruments of free and associated labor. But this is communism, “impossible” communism! Why, those member of the ruling classes who are intelligent enough to perceive the impossibility of continuing the present system and they are many have become the obtrusive and full-mouthed apostles of co-operative production. If co-operative production is not to remain a sham and a snare; if it is to supersede the capitalist system; if united co-operative

societies are to regulate national production upon common plan, thus taking it under their own control, and putting an end to the constant anarchy and periodical convulsions which are the fatality of capitalist production what else, gentlemen, would it be but communism, “possible” communism?

The working class did not expect miracles from the Commune. They have no ready-made utopias to introduce *par decret du peuple*. They know that in order to work out their own emancipation, and along with it that higher form to which present society is irresistably tending by its own economical agencies, they will have to pass through long struggles, through a series of historic processes, transforming circumstances and men. They have no ideals to realize, but to set free the elements of the new society with which old collapsing bourgeois society itself is pregnant. In the full consciousness of their historic mission, and with the heroic resolve to act up to it, the working class can afford to smile at the coarse invective of the gentlemen’s gentlemen with pen and inkhorn, and at the didactic patronage of well-wishing bourgeois-doctrinaires, pouring forth their ignorant platitudes and sectarian crotchets in the oracular tone of scientific infallibility.

When the Paris Commune took the management of the revolution in its own hands; when plain working men for the first time dared to infringe upon the governmental privilege of their “natural superiors”, and, under circumstances of unexampled difficulty, performed it at salaries the highest of which barely amounted to one-fifth what, according to high scientific authority,(1) is the minimum required for a secretary to a certain metropolitan school-board the old world writhed in convulsions of rage at the sight of the Red Flag, the symbol of the Republic of Labor, floating over the Hotel de Ville.

And yet, this was the first revolution in which the working class was openly acknowledged as the only class capable of social initiative, even by the great bulk of the Paris middle class shopkeepers, tradesmen, merchants the wealthy capitalist alone excepted. The Commune had saved them by a sagacious settlement of that ever recurring cause of dispute among the middle class themselves the debtor and creditor accounts. The same portion of the middle class, after they had assisted in putting down the working men’s insurrection of June 1848, had been at once unceremoniously sacrificed to their creditors by the then Constituent Assembly. But this was not their only motive for now rallying around the working class. They felt

there was but one alternative the Commune, or the empire under whatever name it might reappear. The empire had ruined them economically by the havoc it made of public wealth, by the wholesale financial swindling it fostered, by the props it lent to the artificially accelerated centralization of capital, and the concomitant expropriation of their own ranks. It had suppressed them politically, it had shocked them morally by its orgies, it had insulted their Voltairianism by handing over the education of their children to the frères Ignorantins, it had revolted their national feeling as Frenchmen by precipitating them headlong into a war which left only one equivalent for the ruins it made the disappearance of the empire. In fact, after the exodus from Paris of the high Bonapartist and capitalist bohème, the true middle class Party of Order came out in the shape of the “Union Republicaine”, enrolling themselves under the colors of the Commune and defending it against the wilful misconstructions of Thiers. Whether the gratitude of this great body of the middle class will stand the present severe trial, time must show.

The Commune was perfectly right in telling the peasants that “its victory was their only hope”. Of all the lies hatched at Versailles and re-echoed by the glorious European penny-a-liner, one of the most tremendous was that the Rurals represented the French peasantry. Think only of the love of the French peasant for the men to whom, after 1815, he had to pay the milliard indemnity. In the eyes of the French peasant, the very existence of a great landed proprietor is in itself an encroachment on his conquests of 1789. The bourgeois, in 1848, had burdened his plot of land with the additional tax of 45 cents, in the franc; but then he did so in the name of the revolution; while now he had fomented a civil war against revolution, to shift on to the peasant’s shoulders the chief load of the 5 milliards of indemnity to be paid to the Prussian. The Commune, on the other hand, in one of its first proclamations, declared that the true originators of the war would be made to pay its cost. The Commune would have delivered the peasant of the blood tax would have given him a cheap government transformed his present blood-suckers, the notary, advocate, executor, and other judicial vampires, into salaried communal agents, elected by, and responsible to, himself. It would have freed him of the tyranny of the garde champêtre, the gendarme, and the prefect; would have put enlightenment by the schoolmaster in the place of stultification by the priest. And the French peasant is, above all, a man of reckoning. He would find it extremely

reasonable that the pay of the priest, instead of being extorted by the tax-gatherer, should only depend upon the spontaneous action of the parishioners' religious instinct. Such were the great immediate boons which the rule of the Commune and that rule alone held out to the French peasantry. It is, therefore, quite superfluous here to expatiate upon the more complicated but vital problems which the Commune alone was able, and at the same time compelled, to solve in favor of the peasant viz., the hypothecary debt, lying like an incubus upon his parcel of soil, the prolétariat foncier (the rural proletariat), daily growing upon it, and his expropriation from it enforced, at a more and more rapid rate, by the very development of modern agriculture and the competition of capitalist farming.

The French peasant had elected Louis Bonaparte president of the republic; but the Party of Order created the empire. What the French peasant really wants he commenced to show in 1849 and 1850, by opposing his maire to the government's prefect, his school-master to the government's priest, and himself to the government's gendarme. All the laws made by the Party of Order in January and February 1850 were avowed measures of repression against the peasant. The peasant was a Bonapartist, because the Great Revolution, with all its benefits to him, was, in his eyes, personified in Napoleon. This delusion, rapidly breaking down under the Second Empire (and in its very nature hostile to the Rurals), this prejudice of the past, how could it have withstood the appeal of the Commune to the living interests and urgent wants of the peasantry?

The Rurals this was, in fact, their chief apprehension knew that three months' free communication of Communal Paris with the provinces would bring about a general rising of the peasants, and hence their anxiety to establish a police blockade around Paris, so as to stop the spread of the rinderpest.

If the Commune was thus the true representative of all the healthy elements of French society, and therefore the truly national government, it was, at the same time, as a working men's government, as the bold champion of the emancipation of labor, emphatically international. Within sight of that Prussian army, that had annexed to Germany two French provinces, the Commune annexed to France the working people all over the world.

The Second Empire had been the jubilee of cosmopolitan blacklegism, the rakes of all countries rushing in at its call for a share in its orgies and in the plunder of the French people. Even at this moment, the right hand of Thiers is Ganessco, the foul Wallachian, and his left hand is Markovsky, the Russian spy. The Commune admitted all foreigners to the honor of dying for an immortal cause. Between the foreign war lost by their treason, and the civil war fomented by their conspiracy with the foreign invader, the bourgeoisie had found the time to display their patriotism by organizing police hunts upon the Germans in France. The Commune made a German working man its Minister of Labor. Thiers, the bourgeoisie, the Second Empire, had continually deluded Poland by loud professions of sympathy, while in reality betraying her to, and doing the dirty work of, Russia. The Commune honored the heroic sons of Poland by placing them at the head of the defenders of Paris. And, to broadly mark the new era of history it was conscious of initiating, under the eyes of the conquering Prussians on one side, and the Bonapartist army, led by Bonapartist generals, on the other, the Commune pulled down that colossal symbol of martial glory, the Vendôme Column.

The great social measure of the Commune was its own working existence. Its special measures could but betoken the tendency of a government of the people by the people. Such were the abolition of the nightwork of journeymen bakers; the prohibition, under penalty, of the employers' practice to reduce wages by levying upon their workpeople fines under manifold pretexts a process in which the employer combines in his own person the parts of legislator, judge, and executor, and filches the money to boot. Another measure of this class was the surrender to associations of workmen, under reserve of compensation, of all closed workshops and factories, no matter whether the respective capitalists had absconded or preferred to strike work.

The financial measures of the Commune, remarkable for their sagacity and moderation, could only be such as were compatible with the state of a besieged town. Considering the colossal robberies committed upon the city of Paris by the great financial companies and contractors, under the protection of Haussman, the Commune would have had an incomparably better title to confiscate their property than Louis Napoleon had against the Orleans family. The Hohenzollern and the English oligarchs, who both have

derived a good deal of their estates from church plunders, were, of course, greatly shocked at the Commune clearing but 8,000f out of secularization.

While the Versailles government, as soon as it had recovered some spirit and strength, used the most violent means against the Commune; while it put down the free expression of opinion all over France, even to the forbidding of meetings of delegates from the large towns; while it subjected Versailles and the rest of France to an espionage far surpassing that of the Second Empire; while it burned by its gendarme inquisitors all papers printed at Paris, and sifted all correspondence from and to Paris; while in the National Assembly the most timid attempts to put in a word for Paris were howled down in a manner unknown even to the *Chambre introuvable* of 1816; with the savage warfare of Versailles outside, and its attempts at corruption and conspiracy inside Paris would the Commune not have shamefully betrayed its trust by affecting to keep all the decencies and appearances of liberalism as in a time of profound peace? Had the government of the Commune been akin to that of M. Thiers, there would have been no more occasion to suppress Party of Order papers at Paris than there was to suppress Communal papers at Versailles.

It was irritating indeed to the Rurals that at the very same time they declared the return to the church to be the only means of salvation for France, the infidel Commune unearthed the peculiar mysteries of the Picpus nunnery, and of the Church of St. Laurent. It was a satire upon M. Thiers that, while he showered grand crosses upon the Bonapartist generals in acknowledgment of their mastery in losing battles, signing capitulations, and turning cigarettes at Wilhelmshafen, the Commune dismissed and arrested its generals whenever they were suspected of neglecting their duties. The expulsion from, and arrest by, the Commune of one of its members who had slipped in under a false name, and had undergone at Lyons six days' imprisonment for simple bankruptcy, was it not a deliberate insult hurled at the forger, Jules Favre, then still the foreign minister of France, still selling France to Bismarck, and still dictating his orders to that paragon government of Belgium? But indeed the Commune did not pretend to infallibility, the invariable attribute of all governments of the old stamp. It published its doings and sayings, it initiated the public into all its shortcomings.

In every revolution there intrude, at the side of its true agents, men of different stamp; some of them survivors of and devotees to past revolutions,

without insight into the present movement, but preserving popular influence by their known honesty and courage, or by the sheer force of tradition; others mere brawlers who, by dint of repeating year after year the same set of stereotyped declarations against the government of the day, have sneaked into the reputation of revolutionists of the first water. After March 18, some such men did also turn up, and in some cases contrived to play pre-eminent parts. As far as their power went, they hampered the real action of the working class, exactly as men of that sort have hampered the full development of every previous revolution. They are an unavoidable evil: with time they are shaken off; but time was not allowed to the Commune.

Wonderful, indeed, was the change the Commune had wrought in Paris! No longer any trace of the meretricious Paris of the Second Empire! No longer was Paris the rendezvous of British landlords, Irish absentees, American ex-slaveholders and shoddy men, Russian ex-serfowners, and Wallachian boyards. No more corpses at the morgue, no nocturnal burglaries, scarcely any robberies; in fact, for the first time since the days of February 1848, the streets of Paris were safe, and that without any police of any kind.

“We,” said a member of the Commune, “hear no longer of assassination, theft, and personal assault; it seems indeed as if the police had dragged along with it to Versailles all its Conservative friends.”

The cocottes had refound the scent of their protectors the absconding men of family, religion, and, above all, of property. In their stead, the real women of Paris showed again at the surface heroic, noble, and devoted, like the women of antiquity. Working, thinking fighting, bleeding Paris almost forgetful, in its incubation of a new society, of the Cannibals at its gates radiant in the enthusiasm of its historic initiative!

Opposed to this new world at Paris, behold the old world at Versailles that assembly of the ghouls of all defunct regimes, Legitimists and Orleanists, eager to feed upon the carcass of the nation with a tail of antediluvian republicans, sanctioning, by their presence in the Assembly, the slaveholders’ rebellion, relying for the maintenance of their parliamentary republic upon the vanity of the senile mountebank at its head, and caricaturing 1789 by holding their ghastly meetings in the Jeu de Paume.⁽²⁾ There it was, this Assembly, the representative of everything dead in France, propped up to the semblance of life by nothing but the

swords of the generals of Louis Bonaparte. Paris all truth, Versailles all lie; and that lie vented through the mouth of Thiers.

Thiers tells a deputation of the mayors of the Seine-et-Oise “You may rely upon my word, which I have never broken!”

He tells the Assembly itself that “it was the most freely elected and most liberal Assembly France ever possessed”; he tells his motley soldiery that it was “the admiration of the world, and the finest army France ever possessed”; he tells the provinces that the bombardment of Paris by him was a myth: “If some cannon-shots have been fired, it was not the deed of the army of Versailles, but of some insurgents trying to make believe that they are fighting, while they dare not show their faces.” He again tells the provinces that “the artillery of Versailles does not bombard Paris, but only cannonades it”. He tells the Archbishop of Paris that the pretended executions and reprisals (!) attributed to the Versailles troops were all moonshine. He tells Paris that he was only anxious “to free it from the hideous tyrants who oppress it,” and that, in fact, the Paris of the Commune was “but a handful of criminals”.

The Paris of M. Thiers was not the real Paris of the “vile multitude”, but a phantom Paris, the Paris of the francs-fileurs, the Paris of the Boulevards, male and female the rich, the capitalist, the gilded, the idle Paris, now thronging with its lackeys, its blacklegs, its literary bohème, and its cocottes at Versailles, Saint-Denis, Rueil, and Saint-Germain; considering the civil war but an agreeable diversion, eyeing the battle going on through telescopes, counting the rounds of cannon, swearing by their own honor and that of their prostitutes, that the performance was far better got up than it used to be at the Prote St. Martin. The men who fell were really dead; the cries of the wounded were cries in good earnest; and, besides, the whole thing was so intensely historical.

This is the Paris of M. Thiers, as the emigration of Coblenz was the France of M. de Calonne.

The Fall of Paris

The first attempt of the slaveholders' conspiracy to put down Paris by getting the Prussians to occupy it was frustrated by Bismarck's refusal.

The second attempt, that of March 18, ended in the rout of the army and the flight to Versailles of the government, which ordered the whole administration to break up and follow in its track.

By the semblance of peace negotiations with Paris, Thiers found the time to prepare for war against it. But where to find an army? The remnants of the line regiments were weak in number and unsafe in character. His urgent appeal to the provinces to succour Versailles, by their National Guards and volunteers, met with a flat refusal. Brittany alone furnished a handful of Chouans fighting under a white flag, every one of them wearing on his breast the heart of Jesus in white cloth, and shouting "Vive le Roi!" (Long live the King!)

Thiers was, therefore, compelled to collect, in hot haste, a motley crew, composed of sailors, marines, Pontifical Zouaves, Valentin's gendarmes, and Pietri's sergents-de-ville and mouchards. This army, however, would have been ridiculously ineffective without the instalments of imperialist war prisoners, which Bismarck granted in numbers just sufficient to keep the civil war agoing, and keep the Versailles government in abject dependence on Prussia. During the war itself, the Versailles police had to look after the Versailles army, while the gendarmes had to drag it on by exposing themselves at all posts of danger. The forts which fell were not taken, but bought. The heroism of the Federals convinced Thiers that the resistance of Paris was not to be broken by his own strategic genius and the bayonets at his disposal.

Meanwhile, his relations with the provinces became more and more difficult. Not one single address of approval came in to gladden Thiers and his Rurals. Quite the contrary. Deputations and addresses demanding, in a tone anything but respectful, conciliation with Paris on the basis of the unequivocal recognition of the republic, the acknowledgment of the Communal liberties, and the dissolution of the National Assembly, whose mandate was extinct, poured in from all sides, and in such numbers that Dufaure, Thiers' Minister of Justice, in his circular of April 23 to the public

prosecutors, commanded them to treat “the cry of conciliation” as a crime! In regard, however, of the hopeless prospect held out by his campaign, Thiers resolved to shift his tactics by ordering, all over the country, municipal elections to take place on April 30, on the basis of the new municipal law dictated by himself to the National Assembly. What with the intrigues of his prefects, what with police intimidation, he felt quite sanguine of imparting, by the verdict of the provinces, to the National Assembly that moral power it had never possessed, and of getting at last from the provinces the physical force required for the conquest of Paris.

His bandit-warfare against Paris, exalted in his own bulletins, and the attempts of his ministers at the establishment, throughout France, of a reign of terror, Thiers was from the beginning anxious to accompany with a little by-play of conciliation, which had to serve more than one purpose. It was to dupe the provinces, to inveigle the middle class elements in Paris, and above all, to afford the professed republicans in the National Assembly the opportunity of hiding their treason against Paris behind their faith in Thiers.

On March 21, when still without an army, he had declared to the Assembly: “Come what may, I will not send an army to Paris.”

On March 27, he rose again: “I have found the republic an accomplished fact, and I am firmly resolved to maintain it.”

In reality, he put down the revolution at Lyons and Marseilles in the name of the republic, while the roars of his Rurals drowned the very mention of his name at Versailles. After this exploit, he toned down the “accomplished fact” into a hypothetical fact. The Orleans princes, whom he had cautiously warned off Bordeaux, were now, in flagrant breach of the law, permitted to intrigue at Dreux. The concessions held out by Thiers in his interminable interviews with the delegates from Paris and the provinces, although constantly varied in tone and color, according to time and circumstances, did in fact never come to more than the prospective restriction of revenge to the “handful of criminals implicated in the murder of Lecomte and Clement Thomas”, on the well-understood premise that Paris and France were unreservedly to accept M. Thiers himself as the best of possible Republics, as he, in 1830, had done with Louis Philippe, and in 1849 under Louis Bonaparte’s presidency. While out of office, he made a fortune by pleading for the Paris capitalists, and made political capital by pleading against the laws he had himself originated. He now hurried through the National assembly not only a set of repressive laws which were,

after the fall of Paris, to extirpate the last remnants of republican liberty in France; he foreshadowed the fate of Paris by abridging what was for him the too slow procedure of courts-martial, and by a new-fangled, Draconic code of deportation. The Revolution of 1848, abolishing the penalty of death for political crimes, had replaced it by deportation. Louis Bonaparte did not dare, at least not in theory, to re-establish the regime of the guillotine. The Rural Assembly, not yet bold enough even to hint that the Parisians were not rebels, but assassins, had therefore to confine its prospective vengeance against Paris to Dufaure's new code of deportation. Under all these circumstances, Thiers himself could not have gone on with his comedy of conciliation, had it not, as he intended it to do, drawn forth shrieks of rage from the Rurals, whose ruminating mind did neither understand the play, nor its necessities of hypocrisy, tergiversation, and procrastination.

In sight of the impending municipal elections of April 30, Thiers enacted one of his great conciliation scenes on April 27. Amidst a flood of sentiment rhetoric, he exclaimed from the tribune of the Assembly:

“There exists no conspiracy against the republic but that of Paris, which compels us to shed French blood. I repeat it again and again. Let those impious arms fall from the hands which hold them, and chastisement will be arrested at once by an act of peace excluding only the small number of criminals.”

To the violent interruption of the Rurals, he replied:

“Gentlemen, tell me, I implore you, am I wrong? Do you really regret that I could have stated the truth that the criminals are only a handful? Is it not fortunate in the midst of our misfortunes that those who have been capable to shed the blood of Clement Thomas and General Lecomte are but rare exceptions?”

France, however, turned a deaf ear to what Thiers flattered himself to be a parliamentary siren's song. Out of 700,000 municipal councillors returned by the 35,000 communes still left to France, the united Legitimists, Orleanists, and Bonapartists did not carry 8,000.

The supplementary elections which followed were still more decidedly hostile.

Thus, instead of getting from the provinces the badly-needed physical force, the National Assembly lost even its last claim to moral force, that of being the expression of the universal suffrage of the country. To complete

the discomfiture, the newly-chosen municipal councils of all the cities of France openly threatened the usurping Assembly at Versailles with a counter assembly at Bordeaux.

Then the long-expected moment of decisive action had at last come for Bismarck. He peremptorily summoned Thiers to send to Frankfort plenipotentiaries for the definitive settlement of peace. In humble obedience to the call of his master, Thiers hastened to despatch his trusty Jules Favre, backed by Pouyer-Quertier. Pouyer-Quertier, an “eminent” Rouen cotton-spinner, a fervent and even servile partisan of the Second Empire, had never found any fault with it save its commercial treaty with England, prejudicial to his own shop-interest. Hardly installed at Bordeaux as Thiers’ Minister of Finance, he denounced that “unholy” treaty, hinted at its near abrogation, and had even the effrontery to try, although in vain (having counted without Bismarck), the immediate enforcement of the old protective duties against Alsace, where, he said, no previous international treaties stood in the way. This man who considered counter-revolution as a means to put down wages at Rouen, and the surrender of French provinces as a means to bring up the price of his wares in France, was he not the one predestined to be picked out by Thiers as the helpmate of Jules Favre in his last and crowning treason?

On the arrival at Frankfurt of this exquisite pair of plenipotentiaries, bully Bismarck at once met them with the imperious alternative: Either the restoration of the empire or the unconditional acceptance of my own peace terms! These terms included a shortening of the intervals in which war indemnity was to be paid and the continued occupation of the Paris forts by Prussian troops until Bismarck should feel satisfied with the state of things in France; Prussia thus being recognized as the supreme arbiter in internal French politics! In return for this, he offered to let loose for the extermination of Paris the Bonapartist army, and to lend them the direct assistance of Emperor William’s troops. He pledged his good faith by making payment of the first installment of the indemnity dependent on the “pacification” of Paris. Such bait was, of course, eagerly swallowed by Thiers and his plenipotentiaries. They signed the treaty of peace on May 10 and had it endorsed by the Versailles Assembly on the 18th.

In the interval between the conclusion of peace and the arrival of the Bonapartist prisoners, Thiers felt the more bound to resume his comedy of conciliation, as his republican tools stood in sore need of a pretext for

blinking their eyes at the preparations for the carnage of Paris. As late as May 18, he replied to a deputation of middle-class conciliators ““

“Whenever the insurgents will make up their minds for capitulation, the gates of Paris shall be flung wide open during a week for all except the murderers of Generals Clement Thomas and Lecomte.”

A few days afterwards, when violently interpellated on these promises by the Rurals, he refused to enter into any explanations; not, however, without giving them this significant hint:

“I tell you there are impatient men amongst you, men who are in too great a hurry. They must have another eight days; at the end of these eight days there will be no more danger, and the task will be proportionate to their courage and to their capacities.”

As soon as MacMahon was able to assure him, that he could shortly enter Paris, Thiers declared to the Assembly that

“he would enter Paris with the laws in his hands, and demand a full expiation from the wretches who had sacrificed the lives of soldiers and destroyed public monuments.”

As the moment of decision drew near, he said ““ to the Assembly, “I shall be pitiless!” ““ to Paris, that is was doomed; and to his Bonapartist bandits, that they had state licence to wreak vengeance upon Paris to their hearts’ content.

At last, when treachery had opened the gates of Paris to General Douai, on May 21, Thiers, on the 22nd, revealed to the Rurals the “goal” of his conciliation comedy, which they had so obstinately persisted in not understanding.

“I told you a few days ago that we were approaching our goal; today I come to tell you the goal is reached. The victory of order, justice, and civilization is at last won!”

So it was. The civilization and justice of bourgeois order comes out in its lurid light whenever the slaves and drudges of that order rise against their masters. Then this civilization and justice stand forth as undisguised savagery and lawless revenge. Each new crisis in the class struggle between the appropriator and the producer brings out this fact more glaringly. Even the atrocities of the bourgeois in June 1848 vanish before the infamy of 1871. The self-sacrificing heroism with which the population of Paris ““ men, women, and children ““ fought for eight days after the entrance of the Versaillaise, reflects as much the grandeur of their cause, as the infernal

deeds of the soldiery reflect the innate spirit of that civilization, indeed, the great problem of which is how to get rid of the heaps of corpses it made after the battle was over!

To find a parallel for the conduct of Thiers and his bloodhounds we must go back to the times of Sulla and the two Triumvirates of Rome. The same wholesale slaughter in cold blood; the same disregard, in massacre, of age and sex, the same system of torturing prisoners; the same proscriptions, but this time of a whole class; the same savage hunt after concealed leaders, lest one might escape; the same denunciations of political and private enemies; the same indifference for the butchery of entire strangers to the feud.

There is but this difference: that the Romans had no mitrailleuses for the despatch, in the lump, of the proscribed, and that they had not “the law in their hands”, nor on their lips the cry of “civilization.”

And after those horrors look upon the other still more hideous face of the bourgeois civilization as described by its own press!

“With stray shots,” writes the Paris correspondent of a London Tory paper, “still ringing in the distance, and unintended wounded wretches dying amid the tombstones of Pere la Chaise ““ with 6,000 terror-stricken insurgents wandering in an agony of despair in the labyrinth of the catacombs, and wretches hurried through the streets to be shot down in scores by the mitrailleuse ““ it is revolting to see the cafes filled with the votaries of absinthe, billiards, and dominoes; female profligacy perambulating the boulevards, and the sound of revelry disturbing the night from the cabinets particuliers of fashionable restaurants.”

M. Edouard Herve writes in the Journal de Paris, a Versaillist journal pressed by the Commune:

“The way in which the population of Paris manifested its satisfaction yesterday was rather more than frivolous, and we fear it will grow worse as time progresses. Paris has now a fete day appearance, which is sadly out of place; and, unless we are to be called the Parisiens de la decadence, this sort of thing must come to an end.”

And then he quotes the passage from Tacitus:

“Yet, on the morrow of that horrible struggle, even before it was completely over, Rome ““ degraded and corrupt ““ began once more to wallow in the voluptuous slough which was destroying tis body and pulling its soul ““ alibi proelia et vulnera, alibi balnea popinoeque.”

M. Herve only forgets to say that the “population of Paris” he speaks of it but the population of the Paris of M. Thiers ““ the francs-fileurs returning in throngs from Versailles, Saint-Denis, Rueil, and Saint Germain ““ the Paris of the “Decline.”

In all its bloody triumphs over the self-sacrificing champions of a new and better society, that nefarious civilization, based upon the enslavement of labor, drowns the moans of its victims in a hue-and-cry of calumny, reverberated by a world-wide echo. The serene working men’s Paris of the Commune is suddenly changed into a pandemonium by the bloodhounds of “order.”

And what does this tremendous change prove to the bourgeois mind of all countries? Why, that the Commune has conspired against civilization! The Paris people die enthusiastically for the Commune in number unequally in any battle known to history. What does that prove? Why, that the Commune was not the people’s own government but the usurpation of a handful of criminals! The women of Paris joyfully give up their lives at the barricades and on the place of execution. What does this prove? Why, that the demon of the Commune has changed them into Megaera and Hecates!

The moderation of the Commune during the two months of undisputed sway is equalled only by the heroism of its defence.

What does that prove? Why, that for months the Commune carefully hid, under a mask of moderation and humanity, the bloodthirstiness of its fiendish instincts to be let loose in the hour of its agony!

The working men’s Paris, in the act of its heroic self-holocaust, involved in its flames buildings and monuments. While tearing to pieces the living body of the proletariat, its rulers must no longer expect to return triumphantly into the intact architecture of their abodes. The government of Versailles cries, “Incendiarism!” and whispers this cue to all its agents, down to the remotest hamlet, to hunt up its enemies everywhere as suspect of professional incendiarism. The bourgeoisie of the whole world, which looks complacently upon the wholesale massacre after the battle, is convulsed by horror at the desecration of brick and mortar!

When governments give state licences to their navies to “kill, burn, and destroy”, is that licence for incendiarism? When the british troops wantonly set fire to the Capitol at Washington and to the summer palace of the Chinese emperor, was that incendiarism? When the Prussians not for military reasons, but out of the mere spite of revenge, burned down, by the

help of petroleum, towns like Chateaudun and innumerable villages, was that incendiarism? When Thiers, during six weeks, bombarded Paris, under the pretext that he wanted to set fire to those houses only in which there were people, was that incendiarism? ““ In war, fire is an arm as legitimate as any. Buildings held by the enemy are shelled to set them on fire. If their defenders have to retire, they themselves light the flames to prevent the attack from making use of the buildings. To be burned down has always been the inevitable fate of all buildings situated in the front of battle of all the regular armies of the world.

But in the war of the enslaved against their enslavers, the only justifiable war in history, this is by no means to hold good! The Commune used fire strictly as a means of defence. They used it to stop up to the Versailles troops those long, straight avenues which Haussman had expressly opened to artillery-fire; they used it to cover their retreat, in the same way as the Versailles, in their advance, used their shells which destroyed at least as many buildings as the fire of the Commune. It is a matter of dispute, even now, which buildings were set fire to by the defence, and which by the attack. And the defence resorted to fire only then when the Versailles troops had already commenced their wholesale murdering of prisoners.

Besides, the Commune had, long before, given full public notice that if driven to extremities, they would bury themselves under the ruins of Paris, and make Paris a second Moscow, as the Government of National Defence, but only as a cloak for its treason, had promised to do. For this purpose Trochu had found them the petroleum. The Commune knew that its opponents cared nothing for the lives of the Paris people, but cared much for their own Paris buildings. And Thiers, on the other hand, had given them notice that he would be implacable in his vengeance. No sooner had he got his army ready on one side, and the Prussians shutting the trap on the other, than he proclaimed: “I shall be pitiless! The expiation will be complete, and justice will be stern!” If the acts of the Paris working men were vandalism, it was the vandalism of defence in despair, not the vandalism of triumph, like that which the Christians perpetrated upon the really priceless art treasures of heathen antiquity; and even that vandalism has been justified by the historian as an unavoidable and comparatively trifling concomitant to the titanic struggle between a new society arising and an old one breaking down. It was still less the vandalism of Haussman, razing historic Paris to make place for the Paris of the sightseer!

But the execution by the Commune of the 64 hostages, with the Archbishop of Paris at their head! The bourgeoisie and its army, in June 1848, re-established a custom which had long disappeared from the practice of war ““ the shooting of their defenceless prisoners. This brutal custom has since been more or less strictly adhered to by the suppressors of all popular commotions in Europe and India; thus proving that it constitutes a real “progress of civilization”!

On the other hand, the Prussians in France, had re-established the practice of taking hostages ““ innocent men, who, with their lives, were to answer to them for the acts of others. When Thiers, as we have seen, from the very beginning of the conflict, enforced the human practice of shooting down the Communal prisoners, the Commune, to protect their lives, was obliged to resort to the Prussian practice of securing hostages. The lives of the hostages have been forfeited over and over again by the continued shooting of prisoners on the part of the Versailles. How could they be spared any longer after the carnage with which MacMahon’s praetorians celebrated their entrance into Paris?

Was even the last check upon the unscrupulous ferocity of bourgeois governments ““ the taking of hostages ““ to be made a mere sham of?

The real murderer of Archbishop Darboy is Thiers. The Commune again and again had offered to exchange the archbishop, and ever so many priests in the bargain, against the single Blanqui, then in the hands of Thiers. Thiers obstinately refused. He knew that with Blanqui he would give the Commune a head; while the archbishop would serve his purpose best in the shape of a corpse.

Thiers acted upon the precedent of Cavaignac. How, in June 1848, did not Cavaignac and his men of order raise shouts of horror by stigmatizing the insurgents as the assassins of Archbishop Affre! They knew perfectly well that the archbishop had been shot by the soldiers of order. M. Jacquemet, the archbishop’s vicar-general, present on the spot, had immediately afterwards handed them in his evidence to that effect.

All the chorus of calumny, which the Party of Order never fail, in their orgies of blood, to raise against their victims, only proves that the bourgeois of our days considers himself the legitimate successor to the baron of old, who thought every weapon in his own hand fair against the plebeian, while in the hands of the plebeian a weapon of any kind constituted in itself a crime.

The conspiracy of the ruling class to break down the revolution by a civil war carried on under the patronage of the foreign invader ““ a conspiracy which we have traced from the very 4th of September down to the entrance of MacMahon’s praetorians through the gate of St.Cloud ““ culminated in the carnage of Paris. Bismarck gloats over the ruins of Paris, in which he saw perhaps the first instalment of that general destruction of great cities he had prayed for when still a simple Rural in the Prussian Chambre introuvable of 1849. He gloats over the cadavers of the Paris proletariat. For him, this is not only the extermination of revolution, but the extinction of France, now decapitated in reality, and by the French government itself. With the shallowness characteristic of all successful statesmen, he sees but the surface of this tremendous historic event. Whenever before has history exhibited the spectacle of a conqueror crowning his victory by turning into, not only the gendarme, but the hired bravo of the conquered government? There existed no war between Prussia and the Commune of Paris. On the contrary, the Commune had accepted the peace preliminaries, and Prussia had announced her neutrality. Prussia was, therefore, no belligerent. She acted the part of a bravo, a cowardly bravo, because incurring no danger; a hired bravo, because stipulating beforehand the payment of her blood-money of 500 millions on the fall of Paris. And thus, at last, came out the true character of the war, ordained by Providence, as a chastisement of godless and debauched France by pious and moral Germany! And this unparalleled breach of the law of nations, even as understood by the old-world lawyers, instead of arousing the “civilized” governments of Europe to declare the felonious Prussian government, the mere tool of the St. Petersburg Cabinet, an outlaw amongst nations, only incites them to consider whether the few victims who escape the double cordon around Paris are not to be given up to the hangman of Versailles!

That, after the most tremendous war of modern times, the conquering and the conquered hosts should fraternize for the common massacre of the proletariat ““ this unparalleled event does indicate, not, as Bismarck thinks, the final repression of a new society upheaving, but the crumbling into dust of bourgeois society. The highest heroic effort of which old society is still capable is national war; and this is now proved to be a mere governmental humbug, intended to defer the struggle of classes, and to be thrown aside as soon as that class struggle bursts out into civil war. Class rule is no longer

able to disguise itself in a national uniform; the national governments are one as against the proletariat!

After Whit-Sunday, 1871, there can be neither peace nor truce possible between the working men of France and the appropriators of their produce. The iron hand of a mercenary soldiery may keep for a time both classes tied down in common oppression. But the battle must break out again and again in ever-growing dimensions, and there can be no doubt as to who will be the victor in the end ““ the appropriating few, or the immense working majority. And the French working class is only the advanced guard of the modern proletariat.

While the European governments thus testify, before Paris, to the international character of class rule, they cry down the International Working Men’s Association ““ the international counter-organization of labor against the cosmopolitan conspiracy of capital ““ as the head fountain of all these disasters. Thiers denounced it as the despot of labor, pretending to be its liberator. Picard ordered that all communications between the French Internationals and those abroad be cut off; Count Jaubert, Thiers’ mummified accomplice of 1835, declares it the great problem of all civilized governments to weed it out. The Rurals roar against it, and the whole European press joins the chorus. An honorable french writer, completely foreign to our Association, speaks as follows:

“The members of the Central Committee of the National Guard, as well as the greater part of the members of the Commune, are the most active, intelligent, and energetic minds of the International Working Men’s Association... men who are thoroughly honest, sincere, intelligent, devoted, pure, and fanatical in the good sense of the word.”

The police-tinged bourgeois mind naturally figures to itself the International Working Men’s Association as acting in the manner of a secret conspiracy, its central body ordering, from time to time, explosions in different countries. Our Association is, in fact, nothing but the international bond between the most advanced working men in the various countries of the civilized world. Wherever, in whatever shape, and under whatever conditions the class struggle obtains any consistency, it is but natural that members of our Association, should stand in the foreground. The soil out of which it grows is modern society itself. It cannot be stamped out by any amount of carnage. To stamp it out, the governments would have to stamp

out the despotism of capital over labor ““ the condition of their own parasitical existence.

Working men’s Paris, with its Commune, will be forever celebrated as the glorious harbinger of a new society. Its martyrs are enshrined in the great heart of the working class. Its exterminators history has already nailed to that eternal pillory from which all the prayers of their priest will not avail to redeem them.

CRITIQUE OF THE GOTHA PROGRAM, 1875

Anonymous translation

Published after Marx's death, *The Critique of the Gotha Program* is based on a letter written in early May 1875 to the Social Democratic Workers' Party of Germany (SDAP), with whom Marx and Friedrich Engels were in close association. Offering perhaps his most detailed pronouncement on programmatic matters of revolutionary strategy, the text discusses the "dictatorship of the proletariat," the period of transition from capitalism to communism, proletarian internationalism and the party of the working class. *The Critique of the Gotha Program* is also notable for elucidating the principles of "To each according to his contribution" as the basis for a "lower phase" of communist society directly following the transition from capitalism, and "From each according to his ability, to each according to his needs" as the basis for a future "higher phase" of communist society. In describing the lower phase, he states that "the individual receives from society exactly what he gives to it" and advocates remuneration in the form of labour vouchers as opposed to money.

Foreword

The manuscript published here — the covering letter to Bracke as well as the critique of the draft programme — was sent in 1875, shortly before the Gotha Unity Congress, to Bracke for communication to Geib, Auer, Bebel, and Liebknecht and subsequent return to Marx. Since the Halle Party Congress has put the discussion of the Gotha Programme on the agenda of the Party, I think I would be guilty of suppression if I any longer withheld from publicity this important — perhaps the most important — document relevant to this discussion.

But the manuscript has yet another and more far-reaching significance. Here for the first time Marx's attitude to the line adopted by Lassalle in his agitation from the very beginning is clearly and firmly set forth, both as regards Lassalle's economic principles and his tactics.

The ruthless severity with which the draft programme is dissected here, the mercilessness with which the results obtained are enunciated and the shortcomings of the draft laid bare — all this today, after fifteen years, can no longer give offence. Specific Lassalleans now exist only abroad as isolated ruins, and in Halle the Gotha Programme was given up even by its creators as altogether inadequate.

Nevertheless, I have omitted a few sharp personal expressions and judgments where these were immaterial, and replaced them by dots. Marx himself would have done so if he had published the manuscript today. The violence of the language in some passages was provoked by two circumstances. In the first place, Marx and I had been more intimately connected with the German movement than with any other; we were, therefore, bound to be particularly perturbed by the decidedly retrograde step manifested by this draft programme. And secondly, we were at that time, hardly two years after the Hague Congress of the International, engaged in the most violent struggle against Bakunin and his anarchists, who made us responsible for everything that happened in the labour movement in Germany; hence we had to expect that we would also be addled with the secret paternity of this programme. These considerations do not now exist and so there is no necessity for the passages in question.

For reasons arising from the Press Law, also, a few sentences have been indicated only by dots. Where I have had to choose a milder expression this has been enclosed in square brackets. Otherwise the text has been reproduced word for word.

London, January 6, 1891

Letter to Bracke

London, 5 May 1875

Dear Bracke,

When you have read the following critical marginal notes on the Unity Programme, would you be so good as to send them on to Geib and Auer, Bebel and Liebknecht for examination. I am exceedingly busy and have to overstep by far the limit of work allowed me by the doctors. Hence it was anything but a “pleasure” to write such a lengthy screed. It was, however, necessary so that the steps to be taken by me later on would not be misinterpreted by our friends in the Party for whom this communication is intended.

After the Unity Congress has been held, Engels and I will publish a short statement to the effect that our position is altogether remote from the said programme of principle and that we have nothing to do with it.

This is indispensable because the opinion — the entirely erroneous opinion — is held abroad and assiduously nurtured by enemies of the Party that we secretly guide from here the movement of the so-called Eisenach Party [German Social-Democratic Workers Party]. In a Russian book [*Statism and Anarchy*] that has recently appeared, Bakunin still makes me responsible, for example, not only for all the programmes, etc., of that party but even for every step taken by Liebknecht from the day of his cooperation with the People’s Party.

Apart from this, it is my duty not to give recognition, even by diplomatic silence, to what in my opinion is a thoroughly objectionable programme that demoralises the Party.

Every step of real movement is more important than a dozen programmes. If, therefore, it was not possible — and the conditions of the time did not permit it — to go *beyond* the Eisenach programme, one should simply have concluded an agreement for action against the common enemy. But by drawing up a programme of principles (instead of postponing this until it has been prepared for by a considerable period of common activity) one sets up before the whole world landmarks by which it measures the level of the Party movement.

The Lassallean leaders came because circumstances forced them to. If they had been told in advance that there would be haggling about principles, they would *have had* to be content with a programme of action or a plan of organisation for common action. Instead of this, one permits them to arrive armed with mandates, recognises these mandates on one's part as binding, and thus surrenders unconditionally to those who are themselves in need of help. To crown the whole business, they are holding a congress *before the Congress of Compromise*, while one's own party is holding its congress *post festum*. One had obviously had a desire to stifle all criticism and to give one's own party no opportunity for reflection. One knows that the mere fact of unification is satisfying to the workers, but it is a mistake to believe that this momentary success is not bought too dearly.

For the rest, the programme is no good, even apart from its sanctification of the Lassallean articles of faith.

I shall be sending you in the near future the last parts of the French edition of Capital. The printing was held up for a considerable time by a ban of the French Government. The thing will be ready this week or the beginning of next week. Have you received the previous six parts? Please let me have the address of Bernhard Becker, to whom I must also send the final parts.

The bookshop of the Volksstaat has peculiar ways of doing things. Up to this moment, for example, I have not been sent a single copy of the Cologne Communist Trial.

With best regards,

Yours,

Karl Marx

Part I

1. *“Labor is the source of wealth and all culture, and since useful labor is possible only in society and through society, the proceeds of labor belong undiminished with equal right to all members of society.”*

First part of the paragraph: “Labor is the source of all wealth and all culture.”

Labor is *not the source* of all wealth. *Nature* is just as much the source of use values (and it is surely of such that material wealth consists!) as labor, which itself is only the manifestation of a force of nature, human labor power. The above phrase is to be found in all children’s primers and is correct insofar as it is implied that labor is performed with the appurtenant subjects and instruments. But a socialist program cannot allow such bourgeois phrases to pass over in silence the *conditions* that alone give them meaning. And insofar as man from the beginning behaves toward nature, the primary source of all instruments and subjects of labor, as an owner, treats her as belonging to him, his labor becomes the source of use values, therefore also of wealth. The bourgeois have very good grounds for falsely ascribing *supernatural creative power* to labor; since precisely from the fact that labor depends on nature it follows that the man who possesses no other property than his labor power must, in all conditions of society and culture, be the slave of other men who have made themselves the owners of the material conditions of labor. He can only work with their permission, hence live only with their permission.

Let us now leave the sentence as it stands, or rather limps. What could one have expected in conclusion? Obviously this:

“Since labor is the source of all wealth, no one in society can appropriate wealth except as the product of labor. Therefore, if he himself does not work, he lives by the labor of others and also acquires his culture at the expense of the labor of others.”

Instead of this, by means of the verbal river “and since”, a proposition is added in order to draw a conclusion from this and not from the first one.

Second part of the paragraph: “Useful labor is possible only in society and through society.”

According to the first proposition, labor was the source of all wealth and all culture; therefore no society is possible without labor. Now we learn, conversely, that no “useful” labor is possible without society.

One could just as well have said that only in society can useless and even socially harmful labor become a branch of gainful occupation, that only in society can one live by being idle, etc., etc. — in short, once could just as well have copied the whole of Rousseau.

And what is “useful” labor? Surely only labor which produces the intended useful result. A savage — and man was a savage after he had ceased to be an ape — who kills an animal with a stone, who collects fruit, etc., performs “useful” labor.

Thirdly, the conclusion: “Useful labor is possible only in society and through society, the proceeds of labor belong undiminished with equal right to all members of society.”

A fine conclusion! If useful labor is possible only in society and through society, the proceeds of labor belong to society — and only so much therefrom accrues to the individual worker as is not required to maintain the “condition” of labor, society.

In fact, this proposition has at all times been made use of by the champions of the *state of society prevailing at any given time*. First comes the claims of the government and everything that sticks to it, since it is the social organ for the maintenance of the social order; then comes the claims of the various kinds of private property, for the various kinds of private property are the foundations of society, etc. One sees that such hollow phrases are the foundations of society, etc. One sees that such hollow phrases can be twisted and turned as desired.

The first and second parts of the paragraph have some intelligible connection only in the following wording:

“Labor becomes the source of wealth and culture only as social labor”, or, what is the same thing, “in and through society”.

This proposition is incontestably correct, for although isolated labor (its material conditions presupposed) can create use value, it can create neither wealth nor culture.

But equally incontestable is this other proposition:

“In proportion as labor develops socially, and becomes thereby a source of wealth and culture, poverty and destitution develop among the workers, and wealth and culture among the nonworkers.”

This is the law of all history hitherto. What, therefore, had to be done here, instead of setting down general phrases about “labor” and “society”, was to prove concretely how in present capitalist society the material, etc., conditions have at last been created which enable and compel the workers to lift this social curse.

In fact, however, the whole paragraph, bungled in style and content, is only there in order to inscribe the Lassallean catchword of the “undiminished proceeds of labor” as a slogan at the top of the party banner. I shall return later to the “proceeds of labor”, “equal right”, etc., since the same thing recurs in a somewhat different form further on.

2. *“In present-day society, the instruments of labor are the monopoly of the capitalist class; the resulting dependence of the working class is the cause of misery and servitude in all forms.”*

This sentence, borrowed from the Rules of the International, is incorrect in this “improved” edition.

In present-day society, the instruments of labor are the monopoly of the landowners (the monopoly of property in land is even the basis of the monopoly of capital) *and* the capitalists. In the passage in question, the Rules of the International do not mention either one or the other class of monopolists. They speak of the “monopolizer of the means of labor, that is, the *sources of life*.” The addition, “sources of life”, makes it sufficiently clear that land is included in the instruments of labor.

The correction was introduced because Lassalle, for reasons now generally known, attacked *only* the capitalist class and not the landowners. In England, the capitalist class is usually not even the owner of the land on which his factory stands.

3. *“The emancipation of labor demands the promotion of the instruments of labor to the common property of society and the co-operative regulation of the total labor, with a fair distribution of the proceeds of labor.”*

“Promotion of the instruments of labor to the common property” ought obviously to read their “conversion into the common property”; but this is only passing.

What are the “proceeds of labor”? The product of labor, or its value? And in the latter case, is it the total value of the product, or only that part of the value which labor has newly added to the value of the means of production consumed?

“Proceeds of labor” is a loose notion which Lassalle has put in the place of definite economic conceptions.

What is “a fair distribution”?

Do not the bourgeois assert that the present-day distribution is “fair”? And is it not, in fact, the only “fair” distribution on the basis of the present-day mode of production? Are economic relations regulated by legal conceptions, or do not, on the contrary, legal relations arise out of economic ones? Have not also the socialist sectarians the most varied notions about “fair” distribution?

To understand what is implied in this connection by the phrase “fair distribution”, we must take the first paragraph and this one together. The latter presupposes a society wherein the instruments of labor are common property and the total labor is co-operatively regulated, and from the first paragraph we learn that “the proceeds of labor belong undiminished with equal right to all members of society.”

“To all members of society”? To those who do not work as well? What remains then of the “undiminished” proceeds of labor? Only to those members of society who work? What remains then of the “equal right” of all members of society?

But “all members of society” and “equal right” are obviously mere phrases. The kernel consists in this, that in this communist society every worker must receive the “undiminished” Lassalleian “proceeds of labor”.

Let us take, first of all, the words “proceeds of labor” in the sense of the product of labor; then the co-operative proceeds of labor are the *total social product*.

From this must now be deducted: *First*, cover for replacement of the means of production used up. *Second*, additional portion for expansion of production. *Third*, reserve or insurance funds to provide against accidents, dislocations caused by natural calamities, etc.

These deductions from the “undiminished” proceeds of labor are an economic necessity, and their magnitude is to be determined according to available means and forces, and partly by computation of probabilities, but they are in no way calculable by equity.

There remains the other part of the total product, intended to serve as means of consumption.

Before this is divided among the individuals, there has to be deducted again, from it: *First*, the general costs of administration not belonging to production. This part will, from the outset, be very considerably restricted in comparison with present-day society, and it diminishes in proportion as the new society develops. *Second*, that which is intended for the common satisfaction of needs, such as schools, health services, etc. From the outset, this part grows considerably in comparison with present-day society, and it grows in proportion as the new society develops. *Third*, funds for those unable to work, etc., in short, for what is included under so-called official poor relief today.

Only now do we come to the “distribution” which the program, under Lassallean influence, alone has in view in its narrow fashion — namely, to that part of the means of consumption which is divided among the individual producers of the co-operative society.

The “undiminished” proceeds of labor have already unnoticeably become converted into the “diminished” proceeds, although what the producer is deprived of in his capacity as a private individual benefits him directly or indirectly in his capacity as a member of society.

Just as the phrase of the “undiminished” proceeds of labor has disappeared, so now does the phrase of the “proceeds of labor” disappear altogether.

Within the co-operative society based on common ownership of the means of production, the producers do not exchange their products; just as little does the labor employed on the products appear here as the *value* of these products, as a material quality possessed by them, since now, in contrast to capitalist society, individual labor no longer exists in an indirect fashion but directly as a component part of total labor. The phrase “proceeds of labor”, objectionable also today on account of its ambiguity, thus loses all meaning.

What we have to deal with here is a communist society, not as it has *developed* on its own foundations, but, on the contrary, just as it *emerges* from capitalist society; which is thus in every respect, economically, morally, and intellectually, still stamped with the birthmarks of the old society from whose womb it emerges. Accordingly, the individual producer receives back from society — after the deductions have been made —

exactly what he gives to it. What he has given to it is his individual quantum of labor. For example, the social working day consists of the sum of the individual hours of work; the individual labor time of the individual producer is the part of the social working day contributed by him, his share in it. He receives a certificate from society that he has furnished such-and-such an amount of labor (after deducting his labor for the common funds); and with this certificate, he draws from the social stock of means of consumption as much as the same amount of labor cost. The same amount of labor which he has given to society in one form, he receives back in another.

Here, obviously, the same principle prevails as that which regulates the exchange of commodities, as far as this is exchange of equal values. Content and form are changed, because under the altered circumstances no one can give anything except his labor, and because, on the other hand, nothing can pass to the ownership of individuals, except individual means of consumption. But as far as the distribution of the latter among the individual producers is concerned, the same principle prevails as in the exchange of commodity equivalents: a given amount of labor in one form is exchanged for an equal amount of labor in another form.

Hence, *equal right* here is still in principle — *bourgeois right*, although principle and practice are no longer at loggerheads, while the exchange of equivalents in commodity exchange exists only on the average and not in the individual case.

In spite of this advance, this equal right is still constantly stigmatized by a bourgeois limitation. The right of the producers is *proportional* to the labor they supply; the equality consists in the fact that measurement is made with an *equal standard*, labor.

But one man is superior to another physically, or mentally, and supplies more labor in the same time, or can labor for a longer time; and labor, to serve as a measure, must be defined by its duration or intensity, otherwise it ceases to be a standard of measurement. This *equal right* is an unequal right for unequal labor. It recognizes no class differences, because everyone is only a worker like everyone else; but it tacitly recognizes unequal individual endowment, and thus productive capacity, as a natural privilege. It is, therefore, a right of inequality, in its content, like every right. Right, by its very nature, can consist only in the application of an equal standard; but unequal individuals (and they would not be different individuals if they

were not unequal) are measurable only by an equal standard insofar as they are brought under an equal point of view, are taken from one definite side only — for instance, in the present case, are regarded only *as workers* and nothing more is seen in them, everything else being ignored. Further, one worker is married, another is not; one has more children than another, and so on and so forth. Thus, with an equal performance of labor, and hence an equal in the social consumption fund, one will in fact receive more than another, one will be richer than another, and so on. To avoid all these defects, right, instead of being equal, would have to be unequal.

But these defects are inevitable in the first phase of communist society as it is when it has just emerged after prolonged birth pangs from capitalist society. Right can never be higher than the economic structure of society and its cultural development conditioned thereby.

In a higher phase of communist society, after the enslaving subordination of the individual to the division of labor, and therewith also the antithesis between mental and physical labor, has vanished; after labor has become not only a means of life but life's prime want; after the productive forces have also increased with the all-around development of the individual, and all the springs of co-operative wealth flow more abundantly — only then then can the narrow horizon of bourgeois right be crossed in its entirety and society inscribe on its banners: From each according to his ability, to each according to his needs!

I have dealt more at length with the “undiminished” proceeds of labor, on the one hand, and with “equal right” and “fair distribution”, on the other, in order to show what a crime it is to attempt, on the one hand, to force on our Party again, as dogmas, ideas which in a certain period had some meaning but have now become obsolete verbal rubbish, while again perverting, on the other, the realistic outlook, which it cost so much effort to instill into the Party but which has now taken root in it, by means of ideological nonsense about right and other trash so common among the democrats and French socialists.

Quite apart from the analysis so far given, it was in general a mistake to make a fuss about so-called distribution and put the principal stress on it.

Any distribution whatever of the means of consumption is only a consequence of the distribution of the conditions of production themselves. The latter distribution, however, is a feature of the mode of production itself. The capitalist mode of production, for example, rests on the fact that

the material conditions of production are in the hands of nonworkers in the form of property in capital and land, while the masses are only owners of the personal condition of production, of labor power. If the elements of production are so distributed, then the present-day distribution of the means of consumption results automatically. If the material conditions of production are the co-operative property of the workers themselves, then there likewise results a distribution of the means of consumption different from the present one. Vulgar socialism (and from it in turn a section of the democrats) has taken over from the bourgeois economists the consideration and treatment of distribution as independent of the mode of production and hence the presentation of socialism as turning principally on distribution. After the real relation has long been made clear, why retrogress again?

4. *“The emancipation of labor must be the work of the working class, relative to which all other classes are only one reactionary mass.”*

The first strophe is taken from the introductory words of the Rules of the International, but “improved”. There it is said: “The emancipation of the working class must be the act of the workers themselves”; here, on the contrary, the “working class” has to emancipate — what? “Labor.” Let him understand who can.

In compensation, the antistrophe, on the other hand, is a Lassalleian quotation of the first water: “relative to which” (the working class) “all other classes are only one reactionary mass.”

In the Communist Manifesto it is said:

“Of all the classes that stand face-to-face with the bourgeoisie today, the proletariat alone is a really revolutionary class. The other classes decay and finally disappear in the face of modern industry; the proletariat is its special and essential product.”

The bourgeoisie is here conceived as a revolutionary class — as the bearer of large-scale industry — relative to the feudal lords and the lower middle class, who desire to maintain all social positions that are the creation of obsolete modes of production. thus, they do not form together with the bourgeoisie “only one reactionary mass”.

On the other hand, the proletariat is revolutionary relative to the bourgeoisie because, having itself grown up on the basis of large-scale industry, it strives to strip off from production the capitalist character that

the bourgeoisie seeks to perpetuate. But the *Manifesto* adds that the “lower middle class” is becoming revolutionary “in view of [its] impending transfer to the proletariat”.

From this point of view, therefore, it is again nonsense to say that it, together with the bourgeoisie, and with the feudal lords into the bargain, “form only one reactionary mass” relative to the working class.

Has one proclaimed to the artisan, small manufacturers, etc., and peasants during the last elections: Relative to us, you, together with the bourgeoisie and feudal lords, form one reactionary mass?

Lassalle knew the Communist Manifesto by heart, as his faithful followers know the gospels written by him. If, therefore, he has falsified it so grossly, this has occurred only to put a good color on his alliance with absolutist and feudal opponents against the bourgeoisie.

In the above paragraph, moreover, his oracular saying is dragged in by main force without any connection with the botched quotation from the Rules of the International. Thus, it is simply an impertinence, and indeed not at all displeasing to Herr Bismarck, one of those cheap pieces of insolence in which the Marat of Berlin deals. [Marat of Berlin a reference to Hasselmann, chief editor of the *Neuer Social-Demokrat*]

5. “*The working class strives for its emancipation first of all within the framework of the present-day national states, conscious that the necessary result of its efforts, which are common to the workers of all civilized countries, will be the international brotherhood of peoples.*”

Lassalle, in opposition to the Communist Manifesto and to all earlier socialism, conceived the workers’ movement from the narrowest national standpoint. He is being followed in this — and that after the work of the International!

It is altogether self-evident that, to be able to fight at all, the working class must organize itself at home as a class and that its own country is the immediate arena of its struggle — insofar as its class struggle is national, not in substance, but, as the Communist Manifesto says, “in form”. But the “framework of the present-day national state”, for instance, the German Empire, is itself, in its turn, economically “within the framework” of the world market, politically “within the framework” of the system of states. Every businessman knows that German trade is at the same time foreign

trade, and the greatness of Herr Bismarck consists, to be sure, precisely in his pursuing a kind of *international* policy.

And to what does the German Workers' party reduce its internationalism? To the consciousness that the result of its efforts will be "the international brotherhood of peoples" — a phrase borrowed from the bourgeois League of Peace and Freedom, which is intended to pass as equivalent to the international brotherhood of working classes in the joint struggle against the ruling classes and their governments. Not a word, therefore, about the international functions of the German working class! And it is thus that it is to challenge its own bourgeoisie — which is already linked up in brotherhood against it with the bourgeois of all other countries — and Herr Bismarck's international policy of conspiracy.

In fact, the internationalism of the program stands *even infinitely below* that of the Free Trade party. The latter also asserts that the result of its efforts will be "the international brotherhood of peoples". But it also does something to make trade international and by no means contents itself with the consciousness that all people are carrying on trade at home.

The international activity of the working classes does not in any way depend on the existence of the International Working Men's Association. This was only the first attempt to create a central organ for the activity; an attempt which was a lasting success on account of the impulse which it gave but which was no longer realizable in its historical form after the fall of the Paris Commune.

Bismarck's Norddeutsche was absolutely right when it announced, to the satisfaction of its master, that the German Workers' party had sworn off internationalism in the new program.

Part II

“Starting from these basic principles, the German workers’ party strives by all legal means for the free state — and — socialist society: that abolition of the wage system together with the iron law of wages — and — exploitation in every form; the elimination of all social and political inequality.”

I shall return to the “free” state later.

So, in future, the German Workers’ party has got to believe in Lassalle’s “iron law of wages”! That this may not be lost, the nonsense is perpetrated of speaking of the “abolition of the wage system” (it should read: system of wage labor), “together with the iron law of wages”. If I abolish wage labor, then naturally I abolish its laws also, whether they are of “iron” or sponge. But Lassalle’s attack on wage labor turns almost solely on this so-called law. In order, therefore, to prove that Lassalle’s sect has conquered, the “wage system” must be abolished “together with the iron law of wages” and not without it.

It is well known that nothing of the “iron law of wages” is Lassalle’s except the word “iron” borrowed from Goethe’s “great, eternal iron laws”. The word “iron” is a label by which the true believers recognize one another. But if I take the law with Lassalle’s stamp on it, and consequently in his sense, then I must also take it with his substantiation for it. And what is that? As Lange already showed, shortly after Lassalle’s death, it is the Malthusian theory of population (preached by Lange himself). But if this theory is correct, then again I cannot abolish the law even if I abolish wage labor a hundred times over, because the law then governs not only the system of wage labor but *every* social system. Basing themselves directly on this, the economists have been proving for 50 years and more that socialism cannot abolish poverty, which has its basis in nature, but can only make it *general*, distribute it simultaneously over the whole surface of society!

But all this is not the main thing. Quite apart from the false Lassallean formulation of the law, the truly outrageous retrogression consists in the following:

Since Lassalle's death, there has asserted itself in our party the scientific understanding that wages are not what they appear to be — namely, the *value*, or *price*, of *labor* — but only a masked form for the *value*, or *price*, of *labor power*. Thereby, the whole bourgeois conception of wages hitherto, as well as all the criticism hitherto directed against this conception, was thrown overboard once and for all. It was made clear that the wage worker has permission to work for his own subsistence — that is, to *live*, only insofar as he works for a certain time gratis for the capitalist (and hence also for the latter's co-consumers of surplus value); that the whole capitalist system of production turns on the increase of this gratis labor by extending the working day, or by developing the productivity — that is, increasing the intensity or labor power, etc.; that, consequently, the system of wage labor is a system of slavery, and indeed of a slavery which becomes more severe in proportion as the social productive forces of labor develop, whether the worker receives better or worse payment. And after this understanding has gained more and more ground in our party, some return to Lassalle's dogma although they must have known that Lassalle *did not know* what wages were, but, following in the wake of the bourgeois economists, took the appearance for the essence of the matter.

It is as if, among slaves who have at last got behind the secret of slavery and broken out in rebellion, a slave still in thrall to obsolete notions were to inscribe on the program of the rebellion: Slavery must be abolished because the feeding of slaves in the system of slavery cannot exceed a certain low maximum!

Does not the mere fact that the representatives of our party were capable of perpetrating such a monstrous attack on the understanding that has spread among the mass of our party prove, by itself, with what criminal levity and with what lack of conscience they set to work in drawing up this compromise program!

Instead of the indefinite concluding phrase of the paragraph, "the elimination of all social and political inequality", it ought to have been said that with the abolition of class distinctions all social and political inequality arising from them would disappear of itself.

Part III

“The German Workers’ party, in order to pave the way to the solution of the social question, demands the establishment of producers’ co-operative societies with state aid under the democratic control of the toiling people. The producers’ co-operative societies are to be called into being for industry and agriculture on such a scale that the socialist organization of the total labor will arise from them.”

After the Lassallean “iron law of wages”, the physic of the prophet. The way to it is “paved” in worthy fashion. In place of the existing class struggle appears a newspaper scribbler’s phrase: “the social *question*”, to the “solution” of which one “paves the way”.

Instead of arising from the revolutionary process of transformation of society, the “socialist organization of the total labor” “arises” from the “state aid” that the state gives to the producers’ co-operative societies and which the *state*, not the workers, “calls into being”. It is worthy of Lassalle’s imagination that with state loans one can build a new society just as well as a new railway!

From the remnants of a sense of shame, “state aid” has been put — under the democratic control of the “toiling people”.

In the first place, the majority of the “toiling people” in Germany consists of peasants, not proletarians.

Second, “democratic” means in German “Volksherrschaftlich” [by the rule of the people]. But what does “control by the rule of the people of the toiling people” mean? And particularly in the case of a toiling people which, through these demands that it puts to the state, expresses its full consciousness that it neither rules nor is ripe for ruling!

It would be superfluous to deal here with the criticism of the recipe prescribed by Buchez in the reign of Louis Philippe, in opposition to the French socialists and accepted by the reactionary workers, of the Atelier. The chief offense does not lie in having inscribed this specific nostrum in the program, but in taking, in general, a retrograde step from the standpoint of a class movement to that of a sectarian movement.

That the workers desire to establish the conditions for co-operative production on a social scale, and first of all on a national scale, in their own country, only means that they are working to revolutionize the present conditions of production, and it has nothing in common with the foundation of co-operative societies with state aid. But as far as the present co-operative societies are concerned, they are of value only insofar as they are the independent creations of the workers and not protégés either of the governments or of the bourgeois.

Part IV

I come now to the democratic section.

A. “The free basis of the state.”

First of all, according to II, the German Workers’ party strives for “the free state”.

Free state — what is this?

It is by no means the aim of the workers, who have got rid of the narrow mentality of humble subjects, to set the state free. In the German Empire, the “state” is almost as “free” as in Russia. Freedom consists in converting the state from an organ superimposed upon society into one completely subordinate to it; and today, too, the forms of state are more free or less free to the extent that they restrict the “freedom of the state”.

The German Workers’ party — at least if it adopts the program — shows that its socialist ideas are not even skin-deep; in that, instead of treating existing society (and this holds good for any future one) as the *basis* of the existing state (or of the future state in the case of future society), it treats the state rather as an independent entity that possesses its own intellectual, ethical, and libertarian bases.

And what of the riotous misuse which the program makes of the words “present-day state”, “present-day society”, and of the still more riotous misconception it creates in regard to the state to which it addresses its demands?

“Present-day society” is capitalist society, which exists in all civilized countries, more or less free from medieval admixture, more or less modified by the particular historical development of each country, more or less developed. On the other hand, the “present-day state” changes with a country’s frontier. It is different in the Prusso-German Empire from what it is in Switzerland, and different in England from what it is in the United States. The “present-day state” is therefore a fiction.

Nevertheless, the different states of the different civilized countries, in spite of their motley diversity of form, all have this in common: that they are based on modern bourgeois society, only one more or less capitalistically developed. They have, therefore, also certain essential

characteristics in common. In this sense, it is possible to speak of the “present-day state” in contrast with the future, in which its present root, bourgeois society, will have died off.

The question then arises: What transformation will the state undergo in communist society? In other words, what social functions will remain in existence there that are analogous to present state functions? This question can only be answered scientifically, and one does not get a flea-hop nearer to the problem by a thousand-fold combination of the word ‘people’ with the word ‘state’.

Between capitalist and communist society there lies the period of the revolutionary transformation of the one into the other. Corresponding to this is also a political transition period in which the state can be nothing but *the revolutionary dictatorship of the proletariat*.

Now the program does not deal with this nor with the future state of communist society.

Its political demands contain nothing beyond the old democratic litany familiar to all: universal suffrage, direct legislation, popular rights, a people’s militia, etc. They are a mere echo of the bourgeois People’s party, of the League of Peace and Freedom. They are all demands which, insofar as they are not exaggerated in fantastic presentation, have already been *realized*. Only the state to which they belong does not lie within the borders of the German Empire, but in Switzerland, the United States, etc. This sort of “state of the future” is a present-day state, although existing outside the “framework” of the German Empire.

But one thing has been forgotten. Since the German Workers’ party expressly declares that it acts within “the present-day national state”, hence within its own state, the Prusso-German Empire — its demands would indeed be otherwise largely meaningless, since one only demands what one has not got — it should not have forgotten the chief thing, namely, that all those pretty little gewgaws rest on the recognition of the so-called sovereignty of the people and hence are appropriate only in a *democratic republic*.

Since one has not the courage — and wisely so, for the circumstances demand caution — to demand the democratic republic, as the French workers’ programs under Louis Philippe and under Louis Napoleon did, one should not have resorted, either, to the subterfuge, neither “honest” nor decent, of demanding things which have meaning only in a democratic

republic from a state which is nothing but a police-guarded military despotism, embellished with parliamentary forms, alloyed with a feudal admixture, already influenced by the bourgeoisie, and bureaucratically carpentered, and then to assure this state into the bargain that one imagines one will be able to force such things upon it “by legal means”.

Even vulgar democracy, which sees the millennium in the democratic republic, and has no suspicion that it is precisely in this last form of state of bourgeois society that the class struggle has to be fought out to a conclusion — even it towers mountains above this kind of democratism, which keeps within the limits of what is permitted by the police and not permitted by logic.

That, in fact, by the word “state” is meant the government machine, or the state insofar as it forms a special organism separated from society through division of labor, is shown by the words “the German Workers’ party demands as the economic basis of the state: a single progressive income tax”, etc. Taxes are the economic basis of the government machinery and of nothing else. In the state of the future, existing in Switzerland, this demand has been pretty well fulfilled. Income tax presupposes various sources of income of the various social classes, and hence capitalist society. It is, therefore, nothing remarkable that the Liverpool financial reformers — bourgeois headed by Gladstone’s brother — are putting forward the same demand as the program.

B. “The German Workers’ party demands as the intellectual and ethical basis of the state:

- *“1. Universal and equal elementary education by the state. Universal compulsory school attendance. Free instruction.”*

“Equal elementary education”? What idea lies behind these words? Is it believed that in present-day society (and it is only with this one has to deal) education can be *equal* for all classes? Or is it demanded that the upper classes also shall be compulsorily reduced to the modicum of education — the elementary school — that alone is compatible with the economic conditions not only of the wage-workers but of the peasants as well?

“Universal compulsory school attendance. Free instruction.” The former exists even in Germany, the second in Switzerland and in the United States

in the case of elementary schools. If in some states of the latter country higher education institutions are also “free”, that only means in fact defraying the cost of education of the upper classes from the general tax receipts. Incidentally, the same holds good for “free administration of justice” demanded under A, 5. The administration of criminal justice is to be had free everywhere; that of civil justice is concerned almost exclusively with conflicts over property and hence affects almost exclusively the possessing classes. Are they to carry on their litigation at the expense of the national coffers?

This paragraph on the schools should at least have demanded technical schools (theoretical and practical) in combination with the elementary school.

“Elementary education by the state” is altogether objectionable. Defining by a general law the expenditures on the elementary schools, the qualifications of the teaching staff, the branches of instruction, etc., and, as is done in the United States, supervising the fulfillment of these legal specifications by state inspectors, is a very different thing from appointing the state as the educator of the people! Government and church should rather be equally excluded from any influence on the school. Particularly, indeed, in the Prusso-German Empire (and one should not take refuge in the rotten subterfuge that one is speaking of a “state of the future”; we have seen how matters stand in this respect) the state has need, on the contrary, of a very stern education by the people.

But the whole program, for all its democratic clang, is tainted through and through by the Lassalleian sect’s servile belief in the state, or, what is no better, by a democratic belief in miracles; or rather it is a compromise between these two kinds of belief in miracles, both equally remote from socialism.

“Freedom of science” says paragraph of the Prussian Constitution. Why, then, here?.

“Freedom of conscience”! If one desired, at this time of the Kulturkampf to remind liberalism of its old catchwords, it surely could have been done only in the following form: Everyone should be able to attend his religious as well as his bodily needs without the police sticking their noses in. But the Workers’ party ought, at any rate in this connection, to have expressed its awareness of the fact that bourgeois “freedom of conscience” is nothing but the toleration of all possible kinds of religious freedom of conscience from

the witchery of religion. But one chooses not to transgress the “bourgeois” level.

I have now come to the end, for the appendix that now follows in the program does not constitute a characteristic component part of it. Hence, I can be very brief.

Appendix

“2. Normal working day.”

In no other country has the workers' party limited itself to such an indefinite demand, but has always fixed the length of the working day that it considers normal under the given circumstances.

“3. Restriction of female labor and prohibition of child labor.”

The standardization of the working day must include the restriction of female labor, insofar as it relates to the duration, intermissions, etc., of the working day; otherwise, it could only mean the exclusion of female labor from branches of industry that are especially unhealthy for the female body, or are objectionable morally for the female sex. If that is what was meant, it should have been said so.

“Prohibition of child labor.” Here it was absolutely essential to state the age limit.

A general prohibition of child labor is incompatible with the existence of large-scale industry and hence an empty, pious wish. Its realization — if it were possible — would be reactionary, since, with a strict regulation of the working time according to the different age groups and other safety measures for the protection of children, an early combination of productive labor with education is one of the most potent means for the transformation of present-day society.

“4. State supervision of factory, workshop, and domestic industry.”

In consideration of the Prusso-German state, it should definitely have been demanded that the inspectors are to be removable only by a court of law; that any worker can have them prosecuted for neglect of duty; that they must belong to the medical profession.

“5. Regulation of prison labor.”

A petty demand in a general workers' program. In any case, it should have been clearly stated that there is no intention from fear of competition to allow ordinary criminals to be treated like beasts, and especially that there is no desire to deprive them of their sole means of betterment, productive labor. This was surely the least one might have expected from socialists.

“6. An effective liability law.”

It should have been stated what is meant by an “effective” liability law.

Be it noted, incidentally, that, in speaking of the normal working day, the part of factory legislation that deals with health regulations and safety measures, etc., has been overlooked. The liability law comes into operation only when these regulations are infringed.

In short, this appendix also is distinguished by slovenly editing.

Dixi et salvavi animam meam.

[I have spoken and saved my soul.]

MR. GEORGE HOWELL'S HISTORY OF THE INTERNATIONAL WORKING-MEN'S ASSOCIATION

*Published in The Secular Chronicle, And Record of Freethought Progress,
August 4, 1878*

I believe it worth while to illustrate by a few notes the most recent contribution — see the Nineteenth Century of July last — to the extensive spurious literature on the International's History, because its last expounder, Mr. George Howell, an ex-workman and ex-member of the General Council of that Association, may erroneously be supposed to have drawn his wisdom from sources not generally accessible.

Mr. Howell sets about his "History" by passing by the facts that, on September 28th, 1864, I was present at the foundation-meeting of the International, was there chosen a member of the provisional General Council, and soon after drew up the "Inaugural Address," and the "General Statutes" of the Association, first issued at London in 1864, then confirmed by the Geneva Congress of 1866.

So much Mr. Howell knew, but, for purposes of his own, prefers to make "a German Doctor named Karl Marx" first appear at the London "Congress opened on September 25th, 1865." There and then, he avers, the said "doctor" had "sown the seeds of discord and decay by the introduction of the Religious Idea."

In the first instance, no "Congress" of the International took place in September, 1865. A few delegates from the main continental branches of the Association met at London for the sole purpose of conferring with the General Council on the Programme of the "First Congress," which was to assemble at Geneva, in September, 1866. The real business of the Conference was transacted in private sittings, not at the semi-public meetings in Adelphi Terrace, exclusively made mention of by the exact historian, Mr. George Howell.

Like the other representatives of the General Council, I had to secure the acceptance by the Conference of our own programme, on its publication thus characterised, in a letter to the *Siècle*, by the French historian, Henri Martin:

“The breadth of view and the high moral, political, and economical conceptions which have decided the choice of questions composing the programme of the International Congress of Workingmen, which is to assemble next year, will strike with a common sympathy all friends of progress, justice, and liberty in Europe.”

By the way, a paragraph of the programme which I had the honour to indite for the General Council, runs thus:

“The necessity of annihilating the Muscovite influence in Europe, by the application of the principle of the right of nations to dispose of themselves, and the reconstruction of Poland upon a democratic and socialist basis.”

Upon this text Henri Martin put the gloss:

“We will take the liberty of remarking that the expression, ‘democratic and socialist basis’, is a very simple one as regards Poland, where the social framework needs reconstruction quite as much as the political framework, and where this basis has been laid down by the decrees of the anonymous government of 1863, and accepted by all classes of the nation. This, then, is the reply of true socialism, of social progress in harmony with justice and liberty, to the advances of the Communist despotism of Muscovy. This secret of the people of Paris is now becoming the common secret of the peoples of Europe.”

Unfortunately, the “people of Paris” had kept their “secret” so well that, quite unaware of it, two of the Paris delegates to the Conference, Tolain, now a senator of the French Republic, and Fribourg, now a simple renegade, inveighed against the very proposition which was to call forth the enthusiastic comment of the French historian.

The programme of the General Council contained not one syllable on “Religion,” but at the instance of the Paris delegates the forbidden dish got into the bill of fare in store for the prospective Congress, in this dressing:

“Religious Ideas (not “The Religious Idea,” as Howell’s spurious version has it), their influence on the social, political and intellectual movement.”

The topic of discussion thus introduced by the Paris delegates was left in their keeping. In point of fact, they dropped it at the Geneva Congress of 1866, and no one else picked it up.

The London “Congress” of 1865, the “Introduction” there by “a German Doctor named Karl Marx” of the “Religious Idea,” and the fierce feud thence arising within the International — this, his triple myth, Mr. George Howell caps by a legend. He says:

“In the Draft Address to the American people with regard to the abolition of slavery, the sentence, ‘God made of one blood all nations of men’, was struck out, etc.”

Now the General Council issued an address, not to the American people, but to its President, Abraham Lincoln, which he gracefully acknowledged. The address, written by me, underwent no alteration whatever. As the words “God made of one blood all nations of men” had never figured in it, they could not be “struck out.”

The attitude of the General Council in regard to the “Religious Idea” is clearly shown by the following incident: — One of the Swiss branches of the Alliance, founded by Michael Bakunin, and calling itself Section des athées Socialistes, requested its admission to the International from the General Council, but got the reply: “Already in the case of the Young Men’s Christian Association the Council has declared that it recognizes no theological sections. (See page 13 of *Les prétendues scissions dans l’Internationale Circulaire du Conseil Général*, printed at Geneva.)”

Even Mr. George Howell, at that time not yet become a convert by close study of the Christian Reader, consummated his divorce from the International, not at the call of the “Religious Idea,” but on grounds altogether secular. At the foundation of the Commonwealth as the “special organ” of the General Council, he canvassed keenly the “proud position” of Editor. Having failed in his “ambitious” attempt, he waxed sulky, his zeal grew less and less, and soon after he was no more heard of. During the most eventful period of the International he was therefore an outsider.

Conscious of his utter incompetence to trace the history of the Association, but at the same time eager to spice his article with strange revelations, he catches at the appearance, during the Fenian troubles, of General Cluseret in London where, we are told, at the Black Horse, Rathbone Place, Oxford-street, the General met “a few men — fortunately Englishmen,” in order to initiate them into his “plan” of “a general insurrection.” I have some reason to doubt the genuineness of the anecdote, but suppose it to be true, what else would it prove but that Cluseret was not such a fool as to intrude his person and his “plan” upon the General

Council, but kept both of them wisely in reserve for “a few Englishmen” of Mr. Howell’s acquaintance, unless the latter himself be one of these stout fellows in buckram who, by their “fortunate” interference, contrived to save the British Empire and Europe from universal convulsion.

Mr. George Howell has another dark secret to disclose.

At the beginning of June, 1871, the General Council put forth an Address on the Civil War in France, welcomed on the part of the London press by a chorus of execration. One weekly fell foul of ‘the infamous author — , cowardly concealing his name behind the screen of the General Council. Thereupon I declared in *The Daily News* that I was the author. This stale secret Mr. George Howell reveals, in July, 1878, with all the consequentiality of the man behind the curtain.

“The writer of that Address was Dr. Karl Marx. ...Mr. George Odger and Mr. Lucraft, both of whom were members of the Council when it (sic!) was adopted, repudiated it on its publication.”

He forgets to add that the other nineteen British members present acclaimed the “Address.”

Since then, the statements of this Address have been fully borne out by the Enquires of the French Rural Assembly, the evidence taken before the Versailles Courts-Martial, the trial of Jules Favre, and the memoirs of persons far from hostile to the victors.

It is in the natural order of things that an English historian of Mr. George Howell’s sound erudition should haughtily ignore French prints, whether official or not. But I confess to a feeling of disgust when, on such occasions for instance as the Hödel and Nobiling attempts, I behold great London papers ruminating the base calumnies, which their own correspondents, eye-witnesses, had been the first to refute.

Mr. Howell reaches the climax of snobbism in his account of the exchequer of the General Council.

The Council, in its published Report to the Congress of Basle (1869), ridicules the huge treasure with which the busy tongue of the European police and the wild imagination of the capitalist had endowed it. It says,

“If these people, though good Christians, had happened to live at the time of nascent Christianity, they would have hurried to a Roman bank there to pry into St. Paul’s balance.”

Mr. Ernest Renan who, it is true, falls somewhat short of Mr. George Howell’s standard of orthodoxy, even fancies the state of the primitive

Christian communes sapping the Roman Empire might be best illustrated by that of the International Sections.

Mr. George Howell, as a writer, is what the crystallographer would call a “Pseudomorph,” his outer form of penmanship being but imitative of the manner of thought and style “natural” to the English moneyed man of sated virtue and solvent morals. Although he borrows his array of “figures” as to the resources of the General Council from the accounts yearly laid by that same Council before a public “International Congress,” Mr. George Howell must not derogate from his “imitative” dignity by stooping to touch the obvious question: how came it to pass that, instead of taking comfort from the lean budgets of the General Council, all the governments of Continental Europe took fright at “the powerful and formidable organisation of the International Working-men’s Association, and the rapid development it had attained in a few years.” (See Circular of the Spanish Foreign Minister to the representatives of Spain in Foreign Countries.) Instead of laying the Red Ghost by the simple process of shaking at its face the sorry returns of the General Council, why, in the name of common sense, did the Pope and his bishops exorcise the International, the French Rural Assembly outlaw it, Bismarck — at the Salzburg meeting of the emperors of Austria and Germany — threaten it with a Holy Alliance Crusade, and the White Czar commend it to his terrible “Third Division,” then presided over by the emotional Schouvaloff?

Mr. George Howell condescends to admit: “Poverty is no crime, but it is fearfully inconvenient.” I admit, he speaks by book. The prouder he ought to have felt of his former fellowship with a Working-men’s Association, which won world-wide fame and a place in the history of mankind, not by length of purse, but by strength of mind and unselfish energy.

However, from the lofty standpoint of an insular “philistine,” Mr. George Howell reveals to the “cultured people” of the “Nineteenth Century,” that the International was a “failure,” and has faded away. In reality, the social democratic working-men’s parties organised on more or less national dimensions, in Germany, Switzerland, Denmark, Portugal, Italy, Belgium, Holland, and the United States of America, form as many international groups, no longer single sections thinly scattered through different countries and held together by an eccentric General Council, but the working masses themselves in continuous, active, direct intercourse, cemented by exchange of thought, mutual services, and common aspiration.

After the fall of the Paris Commune, all working class organisation in France was of course temporarily broken, but is now in an incipient state of reforming. On the other hand, despite all political and social obstacles, the Slavs, chiefly in Poland, Bohemia, and Russia, participate at present in this international movement to an extent not to be foreseen by the most sanguine in 1872. Thus, instead of dying out, the International did only pass from its first period of incubation to a higher one where its already original tendencies have in part become realities. In the course of its progressive development, it will yet have to undergo many a change, before the last chapter of its history can be written.

NOTES ON ADOLPH WAGNER, 1883

Anonymous translation

Notes on Adolph Wagner's "Lehrbuch der politischen Ökonomie"

1. Mr. Wagner's conception, the "*socio-legal conception*" (p. 2).^[1] Thereby finds himself "*in accord with Rodbertus, Lange and Schäffle*" (p. 2). For the "*main points of the foundation*" he refers to *Rodbertus and Schäffle*. Mr. Wagner says even of *piracy* as "unlawful acquisition" by *entire peoples* that it is only robbery if "*a true jus gentium*"^[2] is presumed to obtain" (p. 18, Note 3).

His research is primarily devoted to the "*conditions of economic life in a community*" and he "*determines from them the sphere of the economic freedom of the individual*" (p. 2).

"The 'instinct to satisfy one's needs'" ... "does *not* function, and is not meant to function, as a *pure force of nature* but, like every human instinct, it is subject to the guidance of reason and conscience. Every act resulting from it is therefore an *answerable* one, and is always governed by a *moral judgement*, though this is admittedly" (!) "*itself liable to historical change*" (p. 9).

As for "*Labour*" (p. 9, § 2), Mr. Wagner does not distinguish between the *concrete character of each kind of labour* and the *expenditure of labour power* common to all these concrete types of labour (pp. 9, 10).

"Even the *mere management of wealth* for the *purpose of procuring revenue* always necessitates activities which belong to the *concept of labour*, and likewise the *employment* of the income thus acquired for the satisfaction of needs" (p. 10, Note 6).

According to Wagner the *historico-legal* are the "*social categories*" (Note 6, p. 13).

"In particular *natural monopolies of location* have the effect, especially in *urban*" (!natural monopoly of the location in the City of London!) "*conditions, then under the influence of the climate for the agricultural*

production of entire countries, further, *natural monopolies of the specific fertility of the land*, e.g. with especially good vineyards, and indeed even between different peoples, e.g. in the *sale of tropical products* to countries of the temperate zone.” //”One example are the export duties on products of a kind of natural monopoly, which are imposed in some countries (Southern Europe, tropical countries) on the safe assumption that they will be passed on to the foreign consumers” (Note 11, p. 15). In deducing export duties in the Southern countries from this, Mr. Wagner shows that he knows nothing of the “history” of these duties//[^{3]} “that goods at least partially free in nature become purely economic ones, sold as a matter of business to the highest bidder” (p. 15).

The sphere of *regular* exchange (*sale*) of goods is their *market* (p. 21).

Among economic goods: “*Relations to persons and things (res incorporales)*, whose material completeness is based on an abstraction: a) *from absolutely free commerce*: the cases of *customers, firms*, etc., when advantageous relations with other people, which have been formed through human activity, may be granted and acquired *for payment*; b) due to certain *legal limitations of commerce*: exclusive manufacturing rights, real equities, privileges, monopolies, patents, etc.” (pp. 22, 23).

Mr. Wagner subsumes “*services*” under “*economic goods*” (p. 23, Note 2 and p. 28). His real motive in doing so is his desire to portray Privy Councillor Wagner as a “*productive worker*”; for, he says

“the answer is prejudicial to an assessment of all of those classes which *professionally* perform *personal services*, such as *servants*, the members of the *liberal professions*, and hence also of the *state*. Only if services are reckoned in with economic goods, are the aforesaid classes *productive* in the economic sense” (p. 24).

The following is highly characteristic of the way of thinking of Wagner and company:

Rau had observed: it depends on the “*definition of wealth* and also of economic goods” whether “*services* also belong to them or not.”^[4] Where upon Wagner states: “*such a definition*” of “*wealth*” must be “*undertaken which includes services among economic goods*” (p. 28).

“*The decisive reason*” is, however, “that the *means of satisfaction* cannot possibly consist solely of material goods, because *needs are not only related*

to the latter, but also to personal services (in particular those of the state, such as *legal protection*, etc.)” (p. 28).

Wealth:

1. *purely economic ... “the supply of economic goods available at a given time as the real stock for the satisfaction of needs”* is “*wealth as such*,” “parts of the total or people’s or national wealth.”

2. “As an *historico-legal concept ... the stock of economic goods in the possession or Property of an entity*”, “*possession of wealth*” (p. 32). The latter is an *historico-legal relative concept of property*. Property conveys only *certain powers of disposal* and *certain powers of exclusion vis-à-vis others*. The *extent of these powers varies*” //i.e. historically// (p. 34). “All wealth in the second sense is *individual wealth*, the wealth of a physical or a legal entity” (l.c.).

Public wealth,

“in particular the wealth of *compulsory communal economies*, thus especially the wealth of *states, regions and communities*. This wealth is designated for *public use* (such as roads, rivers, etc.) and ownership thereof is assigned to the state etc., as the *legal representative of the public* (nation, local population, etc.) or *it is actual state and communal wealth*, namely, *administrative wealth*, which also goes to make possible the fulfilment of public services, or *finance wealth*, employed by the state to acquire revenues as the means for the fulfilment of its services” (p. 35).

Capital, *capitale*, is a translation of κεφάλειον, signifying the claim in respect of a sum of money, as opposed to the *interest* (τκο). In the Middle Ages there emerged *capitale*, *caput pecuniae* for the main thing, the essential, the original (p. 37). In German the word *Hauptgeld* was used (p. 37).

“*Capital, source of earnings, stock of goods bearing interest: a supply of mobile means of acquisition.*” As opposed to: “*stock for use: a quantity of mobile consumable wares put together in any respect at all*” (p. 38, Note 2).

Circulating and standing capital (p. 38, 2(a) and 2(b)).

Value. According to Mr. Wagner, Marx’s theory of value is the *cornerstone of his socialist system*” (p. 45). Since I have never established a “*socialist system*,” this is a fantasy of Wagner, Schäffle *e tutti quanti*.^[5]

Further: according to which Marx

“finds the *common social substance of exchange-value*, the only value he is here concerned with, in *labour*, the *magnitude of exchange-value* in the socially necessary labour time,” etc. [p. 45].

Nowhere do I speak of “*the common social substance of exchange-value*”; I rather say that exchange-values (*exchange-value*, without at least two of them, does not exist) represent something *common to them*, which “is quite independent of their use-values” //i.e. here their natural form//, namely “*value*.” This is what I write: “Therefore, the common substance that manifests itself in the exchange-relation of exchange-value of commodities, is *their value*. The progress of our investigation will lead us back to exchange-value as the necessary mode of expression or form of appearance of value. For the present, however, we have to consider the nature of value *independently of this, its form*” (p. 13).^[6]

Thus I do not say “the common social substance of exchange-value” is “labour”, and as I deal with the *form of value*, i.e. the development of exchange-value, at some length in a separate section, it would be curious if I were to reduce this “form” to a common social substance,” labour. Mr. Wagner also forgets that for me neither “value” nor “exchange-value” are subjects, but *the commodity*.

Further:

“This” (Marxian) “theory is, however, not so much a general theory of value as a *theory of cost* related to *Ricardo*.” (loc. cit.).

Mr. Wagner could have familiarised himself with the difference between me and Ricardo both from *Capital* and from *Sieber's work*^[7] (if he knew Russian). Ricardo did indeed concern himself with labour solely as a *measure of the magnitude of value*, and was therefore unable to find any link between his theory of value and the nature of money.

When Mr. Wagner says that it is not a “general theory of value,” he is quite right in his own sense, since he means by a general theory of value the hairsplitting over the word “value,” which enables him to adhere to the traditional German professorial confusion between “use-value” and “value,” since both have the word “value” in common. But when he goes on to say that it is a “*theory of cost*,” then either it amounts to a tautology: commodities, as values, only represent something *social*, labour, and as far as the *magnitude of value* of a commodity is determined, according to me, by the *quantity of the labour-time contained*, etc., *in it*, in other words the

normal amount of labour which the production of an article costs, etc.; and Mr. Wagner proves the contrary by declaring that this, etc., theory of value is not the “general” one, because it does not correspond with Mr. Wagner’s view of the “general theory of value.” Or else he says *something incorrect*: *Ricardo* (following Smith) lumps value and production costs together; I have already expressly pointed out in *A Contribution to the Critique of Political Economy* as well as in the notes in *Capital*^[8] that *values* and *production prices* (which merely express in money the costs of production) do *not* coincide. Why not? That I have *not* told Mr. Wagner.

Furthermore, I “proceed arbitrarily” when I

“attribute these costs solely to what is termed labour output in the narrowest sense of the term. That always presupposes proof which is hitherto lacking, namely that the production process is possible entirely without the mediation of the activity of *private capitalists* in amassing and employing capital” (p. 45).

Quite the reverse: instead of foisting such future proofs on me, Mr. Wagner first ought to have proved that *a social production process*, not to mention the production process in general, *did not exist* in the very numerous communities which *existed before the appearance of Private capitalists* (the Old Indian community, the South Slav family community, etc.). Besides, Wagner could only say: the exploitation of the working class by the capitalist class, in short, the character of capitalist production as depicted by Marx, is correct, but he is mistaken in regarding this economy as transitory, while Aristotle, on the contrary, was mistaken in *not* regarding the *slave economy* as transitory.

“As long as such proof has *not* been furnished” //in other words, as long as the capitalist economy exists//, “Then *Profit on capital is also in fact* //the clubfoot or ass’s ear reveals itself here// “a ‘*constitutive*’ element of value, *not* as in the socialist view, simply a *subtraction* from, or ‘*robbery*’ of, the worker” (pp. 45, 46).

What a “*subtraction from the worker*” is, subtraction of his skin, etc., is not evident. At any rate, in my presentation even, “profit on capital” is in actual fact *not* “a *subtraction* from, or robbery of, the worker.” On the contrary, I depict the capitalist as the necessary functionary of capitalist production and demonstrate at great length that he not only “subtracts” or “*robs*” but enforces the *production of surplus value*, thus first helping to

create what is to be subtracted; what is more, I demonstrate in detail that even if *only equivalents* were exchanged in the exchange of commodities, the capitalist — as soon as he pays the worker the real value of his labour-power — would have every right, i.e. such right as corresponds to this mode of production, to *surplus-value*. But all this does not make “profit on capital” the “*constitutive*” element of value but only proves that the value which is not “*constituted*” by the labour of the capitalist contains a portion which he can appropriate “legally,” i.e. without infringing the law corresponding to the exchange of commodities.

“That theory is unduly preoccupied with this single value-determining element” //1. Tautology. The theory is false because Wagner has a “general theory of value” which does not agree with it; his “value” is thus determined by “use-value,” as is actually proved by the professorial salary; 2. Mr. Wagner substitutes for value the “marketprice” at a given time, or the commodity-price diverging from it, which is something very different from value//, “[it considers] the *costs*, not the other, usefulness, *utility*, the *demand* element” //i.e. it does not lump together “value” and *use-value*, which is, after all, such a desirable thing for a born Confusius^[9] like Wagner//.

“Not only does it not correspond to the *formation of exchange-value* in *present-day commerce*”

//he means *price formation*, which does not affect the *determination of value* in any way: moreover, the *formation of exchange-value* certainly does *take place in presentday commerce*, as any speculator, adulterater of goods, etc., knows, and this has nothing in common with *value formation*, but has a keen eye for formed values; what is more, in, e.g., the determination of the *value of labour power* I proceed from the assumption that it is really paid at its full value, which is *in fact not the case*. Mr. Schäffle is of the opinion in *Capitalismus*, etc., that that is “magnanimous” or some such thing. He simply means a scientifically necessary procedure//,

“but neither, as *Schäffle* excellently and *indeed conclusively*” (!) “demonstrates in the *Quintessenz* and especially in the *Socialer Körper*,^[10] does it correspond to conditions as they are *bound to take shape in the Marxian hypothetical social state*.”

//I.e., the social state, which Mr. Schäffle was courteous enough to “shape” for me, is transformed into “*the Marxian*” (not the “social state”

foisted on to Marx in Schäffle's hypothesis).//

“This may be *strikingly* demonstrated with the example of grain and such like, whose *exchange-value* would — owing to the influence of fluctuating harvests when demand is fairly constant — of necessity have to be regulated *in some other way* than *simply according to costs* even in a system of ‘*social taxes*’” [p. 45].

//So many words, so much nonsense. First, I have nowhere spoken of “*social taxes*,” and in my *investigation of value* I have dealt with bourgeois relations, not with the application of this theory of *value* to a “social state” not even constructed by me but by Mr. Schäffle for me. Second, if the price of grain rises after a bad harvest, then its *value* rises, for one thing, because a given amount of labour is *contained in a smaller product*; for another thing, its *selling price* rises by much more still. What has this to do with my theory of value? The more the grain is *sold over its value*, the more other commodities, whether in their natural form or in money form, will be sold *under their value* by exactly the same amount, even if their own money price does *not* fall. The *total value* remains the same, even if the expression of this *total value* in its entirety were to increase in money, in other words, if the sum total of “exchange-value” according to Mr. Wagner were to rise. This is the case if we assume that the *drop in price* of the total of the other commodities does not cover the *over-value price* (excess price) of the grain. But in this case, the exchange-value of money has fallen *pro tanto*^[11] beneath its value; the total value of all commodities does not only remain the *same*, but even remains the same *expressed in money*, if money is included among the commodities. Further: the rise in price of grain beyond the increase in its value determined by the bad harvest will in any case be smaller in the “social state” than it is with present-day profiteering in grain. But then the “social state” will organise production from the outset in such a way that the annual supply of grain is only minimally dependent on changes in the weather. The volume of production including supply and consumption will be rationally regulated. Finally, supposing Schäffle's fantasies about it come true, what is the “social tax” meant to prove for or against my theory of value? Just as little as the coercive measures taken during a food shortage on a ship or in a fortress or during the French Revolution, etc., which pay no regard to *value*; and how terrible for the

“social state” to infringe the *laws of value* of the “capitalist (bourgeois) state,” hence, too, the theory of value! Nothing but infantile rot!//

The same Wagner graciously quotes from Rau:

“In order to avoid misunderstandings, it is necessary to establish what is meant by *value pure and simple*, and *it is in conformity with German usage* to choose *use-value* for this purpose”^[12] (p. 46).

Derivation of the concept of value (p. 46 ff.)

It is from the *value-concept* that *use-value and exchange-value* are supposed to be derived d’abord^[13] by Mr. Wagner, not as with me from a *concretum, the commodity*, and it is interesting to follow this *scholasticism* in its latest *Grundlegung*.^[14]

“It is a *natural* striving of man to arrive at a *clear awareness and understanding* of the *relationship* which inner and outer *goods* bear to his *needs*. This is done through the *appreciation (valuation)* by which *value is attributed* to goods or things of the outside world and this value is *measured*” (p. 46), and he says, p. 12: “All means of satisfying one’s needs are called *goods*.”

Thus, if in the first sentence we replace the word “goods” with its Wagnerian *conceptual content*, then the first sentence of the passage quoted becomes:

“It is a *natural striving of ‘man’* to arrive at a clear awareness and understanding of the *relationship* which ‘the inner and outer means of satisfying his needs’ bear to *his needs*.” We may simplify this sentence somewhat by dropping “the *inner* means,” etc., as Mr. Wagner happens to do immediately in the very next sentence by means of the word “or.”

“*Man*”? If the category “man” is meant here, then he has “no” needs at all; if man in isolated juxtaposition with nature, then each individual must be considered a nongregarious animal; if a man already existing in some kind of society — and this is what Mr. Wagner implies, since his “man” does have a language, even though he lacks a university education — then as a starting-point the specific character of this social man must be presented, i.e. the specific character of the community in which he lives, since in that case production, i.e. *the process by which he makes his living*, already has some kind of social character.

But for a professorial schoolmaster the relations between men and nature are a priori not *practical*, that is, relations rooted in action, but *theoretical*,

and two relations of this kind are packed up together in the first sentence.

First: as the “*outer means of satisfying his needs*” or *outer goods* become transformed into “*things of the outside world*” in the next sentence, the first interlocked relation assumes the following form: man finds himself *in relation to the things of the outside world* as means of satisfying his needs. But men do not by any means begin by “finding themselves in this theoretical relationship to the *things of the outside world*.” They begin, like every animal, by *eating, drinking, etc.*, that is not by “finding themselves” in a relationship, but *actively behaving*, availing themselves of certain things of the outside world by action, and thus satisfying their needs. (They start, then, with production.) By the repetition of this process the capacity of these things to “satisfy their needs” becomes imprinted on their brains; men, like animals, also learn “theoretically” to distinguish the outer things which serve to satisfy their needs from all other. At a certain stage of evolution, after their needs, and the activities by which they are satisfied, have, in the meanwhile, increased and further developed, they will linguistically christen entire classes of these things which they distinguished by experience from the rest of the outside world. This is bound to occur, as in the production process — i.e. the process of appropriating these things — they are continually engaged in active contact amongst themselves and with these things, and will soon also have to struggle against others for these things. But this linguistic label purely and simply expresses as a concept what repeated activity has turned into an experience, namely that certain outer things serve to satisfy the needs of human beings already living in certain social context //this being an essential prerequisite on account of the language//. Human beings only give a special (generic) name to these things because they already know that they serve to satisfy their needs, because they seek to acquire them by more or less frequently repeated activity, and therefore also to keep them in their possession; they call them “goods” or something else which expresses the fact that they use these things in practice, that these things are useful to them, and they give the thing this character of utility as if it possessed it, although it would hardly occur to a sheep that one of its “useful” qualities is that it can be eaten by human beings.

Thus: human beings actually started by appropriating certain things of the outside world as means of satisfying their own needs, etc. etc.; later they reached a point where they *also* denoted *them linguistically* as what they are

for them in their practical experience, namely as *means of satisfying their needs*, as things which “satisfy” them. Now, if one terms the fact that human beings not only treat such things practically, as means of satisfying their needs, but also denote them in their thoughts and then linguistically as things which “*satisfy*” their needs, and hence *themselves* //as long as the need of man is not satisfied he is at *variance* with his needs and thus with himself//; if one terms this, “according to German linguistic usage,” “attributing *value*” to them, then one has proved that the general concept “*value*” stems from the behaviour of human beings towards the things found in the outside world which satisfy their needs, and consequently that this is the *generic concept* of “*value*,” and that all other kinds of value, such as the chemical value [valency]^[15] of the elements, are no more than variations of it.

Deleted in the manuscript:^[16] “In the case of Mr. Wagner, however, this ‘deduction’ becomes even more splendid, since he deals with ‘man’ not with ‘men’. This very simple deduction is expressed by Mr. Wagner like this: “It is a *emph{natural}* striving of man” (read: of the German economics professor), “the relationship” whereby things of the outside world are not only means of satisfying human needs, but are acknowledged linguistically as such, and therefore also serve ...”

It is “the natural striving” of a German economics professor to derive the economic category “value” from a “*concept*,” and this he achieves by simply renaming what is *vulgo*^[17] called “use-value” in political economy as “*value*” pure and simple, “according to German linguistic usage.” And as soon as “value” pure and simple has been found, it serves in turn to *derive* “*use-value*” from “value pure and simple.” To do this, one merely has to replace the “use” fragment, which one dropped earlier, in front of “value” pure and simple.

In fact it is Rau (see p. 88^[18]) who tells us plainly that it “is necessary” (for the German professorial schoolmasters) “to lay down what is meant by *value pure and simple*,” naively adding: “and it is *in accordance with German linguistic usage* to select *use-value* to this end.” //In chemistry the *chemical* valency of an element is the number at which one of its atoms is able to combine with the atoms of other elements. But the combining weight of the atoms is also called “equivalency,” the equal value of different

elements, etc., etc. Therefore one must first define the concept “value pure and simple,” etc., etc.//

If man relates to *things* as “*means of satisfying his needs*,” then he relates to *them* as “*goods*,” according to Wagner. He grants them the attribute of being “goods”; the *content of this operation* is in no way altered by the fact that Mr. Wagner renames this “*attributing value*.” His own lazy consciousness immediately arrives at “an understanding” in the following sentence:

“This is done through the *appreciation (valuation)* by which value is attributed to *goods or things of the outside world* and this value is *measured*” [p. 46].

We shall waste no words on the fact that Mr. Wagner derives *value* from valuation (he himself adds “valuation” in brackets after the word *appreciation* in order to arrive “at a clear awareness and understanding” of the matter). “*Man*” has the “natural striving” to do this, to “appreciate” goods as “*values*,” and thus permits Mr. Wagner to *derive* the promised achievement of the “concept of *value* in general.” Not for nothing does Wagner smuggle in with the word “goods” the phrase “*or the things of the outside world*.” His starting point was that man “relates” to the “things of the outside world,” which are means of satisfying his needs, as to “*goods*.” So he *appreciates* these things by the very fact that he relates to them as “goods.” And we have already had an earlier “paraphrase” for this appreciation, to the effect that, e.g.:

“As a *needy* being, man is in constant contact with the *outside world* surrounding him and *acknowledges that therein lie many of the conditions for his life and well-being*” (p. 8).

This, however, means no more than that he “*appreciates* the things of the outside world” insofar as they satisfy his “needy being,” being means of satisfying his needs and therefore, as we have already heard, relates to them as “goods.”

Now it is possible, particularly if one feels the “natural” professorial “striving” to derive the *concept of value in general*, to do this: to give “the things of the outside world” the attribute of “goods” and *dub* it “*attributing value*” to them. One might also have said: Since man relates to the things of the outside world which satisfy his needs as to “goods,” he “prizes” them, thus attributing “*price*” to them, and thus the derivation of the concept

“*price* pure and simple” by “*man’s*” own methods is supplied *ready cut* to the German professor. Everything that the professor is unable to do himself, he makes “man” do; but this man is himself nothing more than the *professorial man* who claims to have understood the world once he has arranged it under abstract headings. But in so far as “attributing *value*” to the things of the outside world is simply another way of phrasing the expression of giving them the attribute of “*goods*,” this is far from being the same, as Wagner wishes to make out, as attributing “*value*” to the “*goods*” themselves as a designation distinct from their “being goods.” It is simply substituting the word “value” for the word “goods.” //As we have seen, the word “*price*” could also be substituted. Even the word “*treasure*” could be substituted; since “*man*” labels certain “things of the outside world” “*goods*,” he “*treasures*” them, and therefore relates to them as to a “*treasure*.” Thus it can be seen how the three economic categories *value*, *price* and *treasure* could be conjured up by Mr. Wagner at a stroke out of “man’s natural striving” to provide the professor with his bone-headed system of concepts (fancies).// But Mr. Wagner has the dim instinct to step out of his labyrinth of tautology and worm his way into a “further something” or a “something further.” Hence the phrase: “by which *value* is attributed to goods or things of the outside world, etc.” Since the labelling of “things of the outside world” as *goods*, i.e., the distinguishing and fixing of these (in the mind) as *means of satisfying* human needs, is also dubbed by Mr. Wagner “attributing *value* to things,” he can no more call this attributing *value* to “the *goods*” themselves than he could talk about *attributing value* to the “value” of the things of the outside world. But the salto mortale is performed with the words “*attributing value* to *goods* or the things of the outside world.” Wagner should have said: the dubbing of certain things of the outside world “*goods*” may also be called “*attributing value*” to these things and this is the Wagnerian *derivation of the “concept of value”* pure and simple or in general. The *content* is not altered by this *change of linguistic expression*. It is still only the *distinguishing or fixing in the mind of* the things of the outside world which are means of satisfying human needs; in fact, simply the *perception and acknowledgement of certain things of the outside world as means of satisfying the needs of “man”* (who as such, however, is actually suffering from a “need of concepts”).

But Mr. Wagner wishes to make us, or himself, believe that instead of giving two names to the same content he has progressed from the designation “goods” to a further developed *designation* “value,” distinct from the first, and he does this simply by substituting the word “goods” for “things of the outside world,” a process which is further “obscured” by the fact that he *rather* substitutes the “things of the outside world” for “the goods.” His own confusion thus achieves the certain effect of confusing his readers. He might also have reversed this splendid “derivation” as follows. By *differentiating* the things of the outside world, which are means of satisfying his needs, as such means of satisfaction, from the other things of the outside world, and therefore *according them special distinction*, he *pays tribute to them, attributes value to them*, or gives them the *attribute of “value.”* This can also be expressed by saying that he grants them the attribute of “goods” as a characteristic, or respects or values them as “goods.” Thereby the concept “goods” is *attributed* to the “values” or to the things of the outside world. And thus the concept of “goods” in general is “derived” from the concept of “value.” All *derivations* of this kind are simply concerned with *diverting* attention from a problem which one is not capable of solving.

But in the same breath Mr. Wagner proceeds in all haste from the “value” of goods to the “*measurement*” of this value.

The content would remain exactly the same if the word “value” had not been smuggled in at all. It might be said: By dubbing certain things of the outside world which, etc., as “goods,” man will eventually come to compare these “goods” with one another, and according to the hierarchy of his needs will arrange them in a certain order, i.e. if one likes to call it so, “*measure*” them. Wagner may not speak at all of the development of the *real measure of these goods* here, i.e. of the development of their *measure of quantity*, as this would remind the reader too sharply how little what is otherwise meant by “*measure of value*” is dealt with here.

//That the *distinguishing* of (reference to) things of the outside world which are means of satisfying human needs as “goods” may be *dubbed* “attributing value to these things” — this Wagner was able to prove not only by means of “German linguistic usage,” as Rau did, but also: there is the Latin word *dignitas* = *dignity, merit, rank*, etc., which when applied to things also means “value”; *dignitas* is derived from *dignus*, and this from

dic, point out, show, *auszeichnen*, *zeigen*; *dignus* thus means “pointed out”; hence, too, *digitus*, the finger with which one points out a thing, refers to it; Greek δεικ-νυμι, δακ-τυλο (finger); Gothic: *ga-tecta* (*dico*); German: *zeigen*; and we could arrive at a lot more “derivations” bearing in mind that δεικνυμι (or δεικνω) (to make visible, to bring to light, *to refer to*) has the same basic stem as δχομαι — that is δεκ (to hold out, to *take*).//

What a lot of banality, tautological confusion, hairsplitting and underhand manoeuvring Mr. Wagner manages to pack into not quite 7 lines.

No wonder that after this feat, the obscure man (*vir obscurus*) continues with great self-assurance:

“The much disputed *concept of value*, still *obscured* by many *investigations* frequently of *merely apparent depth*, resolves itself” (*indeed*) //rather “involves” itself// “if, as has been done hitherto” //namely by Wagner//, “we take the needs and the *economic nature* of man as our starting-point and on arriving at the *concept of goods* — tie it up with the concept of value” (p. 46).

Here we have the *concept* juggling, whose supposed *development* according to the *vir obscurus* boils down to “*tying up*,” and to a certain extent “*tying on*.”

Further derivation of the concept of value:

Subjective and objective value. Subjective and, in the *most general sense*, the *value of goods*=importance which “is attributed to the goods on account of their usefulness ... not a quality of the things in themselves, even if it objectively presupposes the usefulness of a thing” //thus presupposing “objective” value//. In the *objective* sense one also understands by “value” and “values” the *value-possessing goods*, in which (!) good and value, goods and values *become* essentially “identical concepts” (pp. 46, 47).

After taking what is usually termed “*use-value*” and dubbing it “*value in general*” and then the “*concept of value*” pure and simple, Wagner can surely not fail to recall that the “value” “derived” (!) “in this way” (well, well!) is “*use-value*.” After dubbing “*use-value*” the “*concept of value*” in general, or “*value pure and simple*,” he discovers, on second thought, that he has simply been drivelling on about “*use-value*,” and has thus “derived” it, drivelling and deriving now being for him “essentially” identical mental operations. But at this juncture we discover how subjective the hitherto “objective” confusion of ideas of the aforesaid Mr. Wagner really is. For he

reveals a secret to us. Rodbertus had written a letter to him which may be read in the Tübingen *Zeitschrift*^[19] of 1878, in which he, Rodbertus, expounds why there is “only one kind of value”: use-value.

“I” (Wagner) “have come to support this view, the importance of which I have already emphasised in the first edition” [p. 48].

Of what Rodbertus says, Wagner says:

“This is quite correct and necessitates an alteration of the usual illogical ‘division’ of ‘value’ into *use-value* and *exchange-value*, which I had still undertaken in § 3 [in Wagner § 35] of the first edition” (p. 48, Note 4).

and the same Wagner places me (p. 49, Note) amongst those according to whom “use-value” should be entirely “removed” “from the science.”

All this is “drivel.” *De prime abord*,^[20] I do not proceed from “concepts,” hence neither from the “concept of value,” and am therefore in no way concerned to “divide” it. What I proceed from is the simplest social form in which the product of labour presents itself in contemporary society, and this is the “*commodity*.” This I analyse, initially in the *form in which it appears*. Here I find that on the one hand in its natural form it is a *thing for use*, alias a *use-value*; on the other hand, a *bearer of exchange-value*, and from this point of view it is itself an “exchange-value.” Further analysis of the latter shows me that exchange-value is merely a “*form of appearance*,” an independent way of presenting the *value* contained in the commodity, and then I start on the analysis of the latter. I therefore state explicitly, p. 36, 2nd ed.^[21]: “When, at the beginning of this chapter, we said, in common parlance, that a commodity is both a use-value and an exchange-value, we were, precisely speaking, wrong. A commodity is a use-value or object of utility, and a ‘value’. It manifests itself as this twofold thing which it is, as soon as *its value* assumes an independent *form of appearance distinct* from its natural form — the form of *exchange-value*,” etc. Thus I do not divide *value* into use-value and exchange-value as opposites into which the abstraction “value” splits up, but the *concrete social form* of the product of labour, the “*commodity*,” is on the one hand, use-value and on the other, “value,” not exchange value, since the mere *form of appearance* is not its own *content*.

Second: only a *vir obscurus* who has not understood a word of *Capital* can conclude: Because Marx in a note in the first edition of *Capital* rejects all the German professorial twaddle about “use-value” in general, and refers

readers who want to know something about real use-values to “manuals dealing with merchandise” — for this reason *use-value* plays no part in his work. Naturally it does not play the part of its opposite, of “value,” which has nothing in common with it, except that “value” occurs in the term “use-value.” He might just as well have said that “exchange-value” is discarded by me because it is only the form of appearance of value, and not “value” itself, since for me the “value” of a commodity is neither its use-value nor its exchange value.

When one comes to analyse the “commodity” — the simplest concrete element of economics — one must exclude all relations which have nothing to do with the particular object of the analysis. Therefore I have said in a few lines what there is to say about the commodity in so far as it is a use-value, but on the other hand I have emphasised the *characteristic form* in which use-value — the product of labour — appears here, that is: “A thing can be useful, and the product of human labour, without being a commodity. Whoever [directly] satisfies his needs with the produce of his own labour, creates, indeed, use-values but not commodities. In order to produce commodities, *he must not only produce use-values, but use-values for others, social use-values*” (p. 15).^[22] //This the root of Rodbertus’ “*social use-value*.”// Consequently use-value — as the use-value of a “commodity” itself possesses a specific historical character. In primitive communities in which, e.g., means of livelihood are produced communally and distributed amongst the members of the community, the common product directly satisfies the vital needs of each community member, of each producer; the social character of the product, of the use-value, here lies in its (*common*) *communal character*. //Mr. Rodbertus on the other hand transforms the “social use-value” of the *commodity* into “social use-value” pure and simple, and is hence talking nonsense.//

As may be seen from the above, it would be sheer nonsense, in an analysis of the commodity — since it presents itself on the one hand as a use-value or goods, on the other hand as value” — to “tie up” at this juncture all sorts of banal reflexions about use-values or goods which do not enter into the world of commodities, such as “state goods,” “communal goods,” etc. as Wagner and the German professor *in general* does, or about goods like “health,” etc. Where the state is itself a capitalist producer, as in the exploitation of mines, forests, etc., its product is a “commodity” and hence possesses the specific character of every other commodity.

On the other hand the *vir obscurus* has overlooked the fact that even in my analysis of the commodity I do not come to a halt with its dual way of presenting itself, but immediately proceed to show that in this duality of the commodity there presents itself the dual *character* of the *labour* whose product it is: of *useful* labour, i.e. the concrete modes of the labours which create use-values, and of abstract *labour*, of *labour as expenditure of labour power*, regardless of the “useful” way in which it is expended (on which the presentation of the production process later depends); that in the development of the *value form of the commodity*, in the final instance its money form, and thus of *money*, the *value* of a commodity presents itself in the *use-value* of the other commodity, i.e. in its natural form; that *surplus-value* itself is derived from a “specific” *use-value of labour power* belonging to it exclusively, etc., etc., that, in other words, for me use-value plays an important part quite different from its part in economics hitherto, but *note bene* it still only comes under consideration when such a consideration stems from the analysis with regard to economic formations, not from arguing hither and thither about the concepts or words “use-value” and “value.”

For this reason when analysing the commodity I do not immediately drag in definitions of “capital,” not even when dealing with the “use-value” of the commodity. Such definitions are bound to be sheer nonsense as long as we have advanced no further than the analysis of the elements of the commodity.

What annoys (shocks) Mr. Wagner about my presentation, though, is that I will not do him the favour of complying with the patriotic German professorial “striving” for confusing use-value with value. Although German society is very much *post festum*, it has nevertheless gradually emerged from the feudal subsistence economy, or at least its predominance, into capitalist society, but the professors are still standing with one foot in the old muck — naturally enough. From being the serfs of landowners they have turned into the serfs of the state, vulgo the government. Therefore our *vir obscurus* too, who has not even noticed that my *analytic* method, which does not proceed from *man* but from a given economic period of society, has nothing in common with the German-professorial association-of-concepts method (“words are excellent for fighting with, with words a system may be built”^[23]), therefore he says:

“In harmony with the view of *Rodbertus* and also of *Schäffle* I place the *use-value* character of *all value* in the fore, and emphasise the assessment of use-value all the more, *since* the assessment of exchange-value is simply not applicable to many of the most important economic goods,”

{Was zwingt ihn zu Ausreden? also als Staatsdiener fühlt er sich verpflichtet, Gebrauchswert und Wert zu konfundieren!},

“*neither to the state and its services*, nor to other social economic relations” (p. 49, Note).

//This reminds one of the old chemists before the science of chemistry: as cooking butter, which is simply called butter in everyday life (according to the Nordic custom), has a soft consistency, they called *chloride*, *butter of zinc*, *butter of antimony*, etc. Butter juices, thus, to use the words of the *vir obscurus*, “firmly adhering to the *butter* character of all chlorides, zinc and antimony compounds.”// The whole rigmarole boils down to this: Because certain goods, especially *the state* (goods!) and its “*services*” //Particularly the services of its professors of political economy// are *not* “commodities,” the opposing characteristics contained in the “commodities” themselves //which also appear explicitly in the commodity form of the product of labour// must therefore be confused with one another! In the case of Wagner and Co. it is anyway hard to maintain that they have more to gain if their “services” are determined according to their “use-value,” according to their tangible “content” [*Gehalt*], rather than according to their “*salary*” [*Gehalt*] (through a “social tax,” as Wagner expresses it [p. 45], i.e. are “assessed” according to their *payment*.^[24]

//The only thing which clearly lies at the bottom of the German stupidity is the fact that linguistically the words *value* [*Wert*] or *worth* [*Würde*] were first applied to the useful things themselves, which existed for a long time, even as “products of labour,” before becoming *commodities*. But this has as little to do with the scientific determination of the “value” of the commodity as the fact that the word *salt* was first used by the ancients for cooking salt, and consequently *sugar*, etc. also figure as *varieties of salt* from Pliny onwards (*indeed*, all colourless solids soluble in water and with a peculiar taste), and therefore the chemical category “salt” includes sugar, etc.//

//As the commodity is bought by the purchaser not because it has value but because it is a “use-value,” and is used for definite purposes, it goes without saying that 1. use-values are “assessed,” i.e. their *quality is*

investigated (just as their *quantity* is weighed, measured, etc.); 2. if different sorts of commodities can be substituted for one another for the same use, one or the other will be given preference, etc., etc.//

In Gothic there is only one word for *Wert* and *Würde*: *vairths*, τιμη, // τιμαω, *assess*, i.e. *evaluate*; to determine the *price* or *value*, to *rate*; *metaphorically: to appreciate, esteem, honour, distinguish*. Τιμη — *assessment, hence: determination of value or price, evaluation, valuation*. Then: *estimation, also, value, price itself* (Herodotus, Plato), αι τιμα — *expenses* in *Demosthenes*. Then: *estimation, honour, respect, place of honour, honorary post, etc.*, *Rost's Greek-German Dictionary*.^[25]//

Value, price (Schulze, *Glossar*^[26]) Gothic: *vairths*, adj., ξιο, καν

Old Norse: verdhr; worthy, verdh, value, price; Anglo-Saxon: veordh, vurdh; English: worth, adj. and noun, value and dignity

“*Middle High German: wert, genitive werdes, adj. dignus and likewise pfennincwert, gen. Werdes, value, worth, splendour; aestimatio, commodity of definite value, e.g. pfenwert, Pennyworth; -werde: meritum, aestimatio, dignitas, precious character*” (Ziemann: *Middle High German Dictionary*^[27]).

Wert and *Würde* [value and worth] are thus closely related in both etymology and meaning. What conceals the fact is the *inorganic* (incorrect) *inflexion* of *Wert* which has become customary in Modern High German: *Werth, Werthes* instead of *Werdes*, since Gothic *th* corresponds to High German *d*, not *th* = *t*, and this is indeed still the case in Middle High German (*wert, gen. Werdes, loc. cit.*). According to the rule in Middle High German, *d* at the end of a word became *t*, giving *wert* instead of *werd*, but genitive *Werdes*.

But all this has as much or as little to do with the economic category “value” as with the *chemical valency of the chemical elements* (atomicity) or with the chemical equivalents or equal values (combining weights of the chemical elements).

Furthermore it should be noted that — even in this linguistic connection — if it follows automatically, as if by the nature of the thing, from the original identity of *Würde* and *Wert* that this word also referred to things, products of labour in their natural form — it was later directly applied unchanged to *prices*, i.e. value in its developed value-form, i.e. exchange-value, which has so little to do with the matter that the same word continued

to be used for worth in general, for honorary offices, etc. Thus, linguistically speaking, there is no distinction here between use-value and value.

Let us now turn to the authority quoted by the *vir obscurus*, to *Rodbertus* //whose essay may be scrutinised in the *Tübinger Zeitschrift*//. The passage by Rodbertus cited by the *vir obscurus* is as follows:

From the *text on page 48*:

“There is only one *kind of value*, and that is use-value. This is either *individual* use-value or *social* use-value. The former stands in a relation to the individual and his needs, quite regardless of any social organisation.”

//This is sheer nonsense (cf. *Capital*, p. 171^[28]) where, however, it says that the *labour-process*, as a useful activity for the production of use-values, etc., is “*equally common to all its*” (human life’s) “*forms of society*” and “*is independent of each of them.*”// //First, it is not the word “use-value” which stands in relation to the individual, but *concrete use-values*, and *which of these* “stand in a relation” to him (for these people everything always “stands”; everything is a question of “standing”^[29]) is entirely dependent on the level of the social production process, therefore also corresponding to “a social organisation.” But if Rodbertus only wishes to make the trivial statement that use-value which really stands in relation to an individual as an object of utility, relates to him as an individual use-value for him — then this is either a trivial tautology or it is incorrect, since not to mention such things as rice, maize, wheat or meat //which does not stand in any relation to a Hindu as food//, an individual’s need for the title of Professor or Privy Councillor or an order is possible only in quite a definite “social Organisation”//.

“The second is *use-value*, which a *social* organism consisting of many individual organisms (or individuals) has” (p. 48, text).

Lovely German! Is it the “use-value” of the “social organism” which is meant here, or is it a use-value in the possession of a “social organism” (as e.g. land in primitive communities), or is it the definite “social” form of use-value in a *social organism*, as e.g. in places where commodity production predominates, the use-value which a producer supplies must be a “use-value for others” and in this sense a “social use-value”? This is nothing but hot air and will lead us nowhere.

And so on to the second proposition of Wagner’s Faust^[30]:

“Exchange-Value is simply the historical mantle and appendage of the social use-value from a particular period of history. By taking *an* exchange-value *as the logical opposite* of use-value, *one is* placing an historical concept in logical contrast to a logical concept, which is logically not admissible” (p. 48, Note 4). “That is quite correct!” crows Wagner *ibidem*.

Who is the “one” who is committing this? That Rodbertus means me, we may take for granted, since according to R. Meyer, his *famulus*, he has written a “big, fat manuscript” against *Capital*^[31]. Who is placing things in logical contrast? Mr. Rodbertus, for whom “use-value” and “exchange-value” are both by nature mere “concepts.” In fact in every price-list every individual sort of commodity undergoes this illogical process, distinguishing itself from the others as *goods, use-value*, as cotton, yarn, iron, grain, etc., and representing “goods” qualitatively different from the others *toto coelo*,^[32] but simultaneously representing its *price* as qualitatively the same but quantitatively different of *the same essence*. It presents itself in its natural form for him who uses it, and in *value-form*, which is quite different from it and “common” to all other commodities, i.e. as *exchange-value*. The only “*logical*” contrast here is in Rodbertus and the German professorial schoolmasters related to him who proceed from the “concept” of value, not from the “social thing,” the commodity,” who get this concept to split up into itself (duplicate itself), and then argue about which of these two phantoms of the mind is the real Jacob!^[33]

But what lurks in the gloomy background to these high-flown phrases is simply the immortal discovery that in all circumstances man must eat, drink, etc. //one cannot even continue: “clothe himself, or have a knife and fork or bed and dwelling,” as this is not the case *in all circumstances*//; in short, that in all circumstances he must find external things already available in nature to satisfy his needs and appropriate them or fashion them out of what nature provides; in this actual procedure of his he thus always relates practically to certain external things as “use-values,” i.e. he always treats them as objects for his use; hence according to Rodbertus use-value is a “logical” concept; thus, since man must also breathe, “breathing” is a “logical” concept, but not a “physiological” one at all. The entire shallowness of Rodbertus, however, emerges in his contrast between “logical” and “historical” concepts! He grasps “value” (the economic value, in contrast to the use-value of the commodity) only in its form of appearance, in *exchange-value*, and since this only occurs when at least

some part of the products of labour, the objects of utility, function as “*commodities*” this not, however, happening from the outset, but only at a certain period of social development, in other words, at a definite stage of historical development, then *exchange-value* is a “historical” concept. Now if Rodbertus — and I will point out later why he did not see it — had gone on to analyse the exchange-value of commodities — for it only exists where *commodity* occurs in the plural, different sorts of commodities, then he would have found “value” behind this form of appearance. If he had further gone on to investigate value, he would have further found that here the thing, the “use-value,” amounts to a mere *concretisation* of human labour, as the *expenditure of equal human labour-power*, and therefore this content is presented as the *concrete* character of the *thing*, as a character appertaining essentially to *the thing itself*, although this objectivity does *not* appear in its natural form //which, however, necessitates a special *form of value*//. He would have found, then, that the “value” of the commodity merely expresses in a historically developed form something which also exists in all other historical forms of society, albeit *in a different form, namely the social character of labour*, insofar as it exists as *expenditure of “social” labour-power*. If, then, “the value” of the commodity is merely a particular historical form of something which exists in all forms of society, the same must be true of the “social use-value,” as it characterises the “use-value” of the commodity. Mr. Rodbertus has the measure of the magnitude of value from Ricardo; but he himself has neither examined nor grasped the substance of value any more than Ricardo did; e.g. the “communal” character of the [labour process] in the primitive community as the common organism of the labour-powers belonging together, and hence that of *their labour*, i.e. the expenditure of these powers.

Further treatment of Wagner’s twaddle on this issue superfluous.

Measure of the magnitude of value. Mr. Wagner incorporates me here, but finds to his regret that I have “*eliminated*” the “*labour involved in capital formation*” (p. 58, Note 7.)

“In commerce regulated by social organs, the determination of *tariff values* or *tariff prices* must be carried out with due consideration to this *cost-element*” //his term for the quantum of labour expended in production, etc.//, “as used to happen in principle in the case of the former state and trade tariffs, and would again have to take effect under any *new tariff*

system” //read “socialist”!//. “However, in free commerce the costs are *not* the *sole* basis for determining exchange-values and prices, and cannot be in *any conceivable social situation*. For regardless of costs, there must always occur *fluctuations in use-value and need*, whose influence on *exchange-value and prices* (both contract and tariff prices) then modifies the *influence of costs*, and is bound to do so,” etc. (pp. 58, 59). “The” //i.e. this!// “astute correction of the socialist doctrine of value ... we owe to *Schäffle*” (!) who says in *Soz. Körper*,^[34] III, p. 278: “No matter what kind of social influence over needs and production exists, there is no avoiding the fact that all *needs* always remain in equilibrium qualitatively and quantitatively with production. But if this is so, *the social cost-value quotients cannot simultaneously be considered proportionally as social use-value quotients*” (p. 59, Note 9).

That this merely amounts to the triviality of *market-prices* rising and falling above or below value and to the assumption that the theory of value developed by him for *bourgeois* society is predominant in the “Marxian social state” is shown by Wagner’s phrase:

“They” (prices) “will occasionally deviate from them” [costs] to a lesser or greater extent, rising for goods whose use-value has become greater and falling for those whose use-value has become smaller. Only *in the long run* will costs continually assert themselves as the decisive regulator” etc. (p. 59).

Law. As for the fantasies of the *vir obscurus* about the economically creative influence of the *law*, one phrase will suffice, although he is forever dragging out the absurd point of view which it exemplifies:

“Individual enterprise has at its head, as the organ of its technical and economic activity ..., a *person* as a legal and economic subject. Furthermore, this person is no purely economic entity but at the same time dependent on the arrangement of the *law*. For the latter determines who is to count as a person, and consequently who can stand at the head of a business,” etc. (p. 65).

Communications and transport (pp. 75–76), p. 80 (Note).

From p. 82: where the “*exchange in the (natural) constituents of the mass of goods*” //of an economy, alias dubbed “*exchange of goods*” by Wagner, is declared to be Schäffle’s “*social exchange of matter*” — at least, one case of it; but I also used the word in the “natural” process of

production for the exchange of matter between man and nature// *has been borrowed* from me, where exchange of matter first occurs in the analysis of C-M-C^[35] and interruptions in the exchange of form, later also termed interruptions in the exchange of matter.

What Mr. Wagner goes on to say about the “*inner exchange*” of the goods in one branch of production (in his case an “individual enterprise”), partly with reference to their “use-value,” partly with reference to their “value,” is also discussed by me in the analysis of the first phase of C-M-C, namely C-M, in the example of the linenweaver (Capital, pp. 85, 86/87), where I conclude by saying: “Our owners of commodities therefore find out that the same division of labour that turns them into independent private producers, [also] makes the social process of production and their relations within that process independent of them themselves, and that the seeming mutual independence of the individuals from one another is supplemented by a system of all-round material dependence” (Capital, p. 87)^[36].

Contracts for the commercial acquisition of goods. Here the *vir obscurus* places mine and his on their heads. For him the law is first, and then comes commerce; in reality it is the other way round: first there is commerce, and then a legal system develops out of it. In the analysis of the circulation of commodities I have demonstrated that in developed bartering the participants tacitly acknowledge one another as equal persons and owners of the respective goods to be exchanged by them; they already do that while offering their goods to each other and agreeing to trade with each other. This actual relation, which only arises through and in the exchange, is later given *legal form* in the contract, etc. but this form neither creates its content, the exchange, nor the *relationship between the persons inherent in it*, but vice versa. Wagner, on the other hand:

“*This acquisition*” //of goods through commerce// “necessarily presupposes a definite *legal system*, on *whose basis*” (!) “commerce takes place,” etc. (p. 84).

Credit Instead of giving the development of money as a *means of payment*, Wagner immediately turns the process of circulation, insofar as it occurs in such a form that the two equivalents do not confront each other as C-M at the same time, into a “*credit transaction*” (p. 85 ff.), which is “tied up” with the fact that this is frequently linked with the payment of “interest”; it also serves to “inspire confidence” and thus to depict “confidence” as a basis for “credit.”

About *Puchta's*^[37] etc., juridical conception of “wealth,” according to which *debts*, too, belong to it as *negative components* (p. 86, Note 8).

Credit is “*consumptive credit*” or “*productive credit*” (p. 86). The former^[38] predominating chiefly on a lower level of culture, the latter^[39] on a “higher.”

As for the *causes of debt* //causes of pauperism: fluctuations in the harvest, war service, slave competition// in Ancient Rome (Jhering, 3rd ed., p. 234, II, 2. *Geist des römischen Rechts*).^[40]

According to Mr. Wagner, “consumptive credit” prevails on the “lower level” among “lower, distressed” and “higher, extravagant” classes. *In fact*, in England and America “*consumptive credit*” is *generally prevalent with the development of the deposit-bank system!*

“In particular ... productive credit proves to be an economic factor of the economy based on private ownership of land and movable capital and allowing free competition. It is tied up with the possession of wealth, not with wealth as a purely economic category,” and is therefore only a “historico-legal category” “ (p. 87).

Dependence of individual enterprise and wealth on the effects of the outside world, especially the influence of the state of the economy.

1. *Changes in use-value*: improve in some cases with the *passage of time*, being the condition for certain processes in nature (*wine, cigars, violins*, etc.).

“*Deteriorate* in the great *majority* of cases ... dissolve into their material constituents, *coincidences* of every kind.” Corresponds to “change” in exchange-value in the same direction, “increase in value” or “decrease in value” (pp. 96, 97). *Vid. concerning the house-rent agreement* in Berlin (p. 97, Note 2).

2. *Changes in human knowledge of the properties of the goods*: thereby “*increasing wealth*” in a *positive case*. //Use of coal for the smelting of iron in England around 1620, when the decline in forests was already threatening the existence of the ironworks; chemical discoveries, such as that of iodine (utilisation of iodine-bearing salt springs). Phosphorite as a fertiliser, anthracite as a heating agent. Substances for gas-lighting, photography. Discovery of dyes and medicines. Gutta-percha, rubber. Vegetable ivory (from *Phytelephas macrocarpa*). Creosote. Paraffin-wax candles. The use of *asphalt, of pine-needles* (pine-needle wool), of the gases

in the blast-furnace, coal-tar for the preparation of aniline, woollen rags, sawdust, etc., etc.//. *In negative cases, a decrease in utility and therefore in value* (as following the discovery of trichinae in pork, poisons in dyes, plants, etc.) (pp. 97, 98). Discovery of *mining products* in the earth, of new useful properties of these products, discovery of a new application for them increases *fortune of the landowner* (p. 98).

3. *Economic situation.*

Influence of *all* of the external “conditions,” which “essentially determine the *production of goods for commerce, demand and sale*” ... hence their “*exchange-value*,” also that of “*the individual finished goods*” ... “entirely or mainly *independently*” of the “economic subject,” “or proprietors” (p. 98). *The economic situation becomes a “crucial factor” in the “system of free competition”* (p. 99). Thus someone— “by means of the *Principle of private property*” gains “what he has not *earned*,” and so someone else incurs a “*forfeit*,” “*economically unwarranted losses*.”

Concerning *speculation* (Note 10, p. 101). *Housing prices* (p. 102, Note 11). *Coal and iron industry* (p. 102, Note 12). *Innumerable changes in technology* reduce the value of industrial products as the instruments of production (pp. 102, 103).

In “an economy progressing in population and prosperity, the *favourable chances* ... *preponderate*, albeit with occasional temporary and local setbacks and fluctuations, in the case of *landed property*, especially in the case of *urban (city) property*” (p. 102).

“Thus the economic situation directs profits into the hands of the *landed proprietor*” (p. 103). “These, like most other *profits on value due to the state of the economy* ... are simply *nothing but “gambling winnings*,” to which correspond “*gambling losses*” (p. 103).

Ditto about “Grain Trade” (p. 103, Note 15).

It must thus be “openly acknowledged: ... the economic situation of the individual or family” is “*essentially another product of the economic situation*” and this “necessarily undermines the significance of *personal economic responsibility*” (pp. [104,] 105).

If, therefore, “the *present organisation* of the economy and the *legal basis* for it” (!) “hence private ownership of ... land and capital” etc. is “for them mainly an *immutable institution*,” then, after a good deal of prattle, there are no means “of combatting ... *the causes*” //of the ensuing evils,

such as stagnation in sales, crises, the dismissal of workers, wage-cuts, etc.//, “hence *not* of the evil itself,” whereas Mr. Wagner imagines he is combatting the “symptoms,” the “consequences of the evil” by meeting “*profits arising from the state of the economy*” with “taxes” — the “*losses*,” “economically unwarranted,” the product of the state of the economy, by a “rational ... *system of insurance*” (p. 105).

This, says the obscure man, is the result of considering the present mode of production and its “legal basis” as “immutable”; but his research, going more deeply than socialism, will get to grips with the “issue itself.” *Nous verrons*,^[41] won’t we?

Chief individual elements affecting the state of the economy.

1. *Fluctuations in the harvest yields of staple foods* under the influence of the weather and political conditions, such as disruptions in cultivation due to war. Producers and consumers affected by it (p. 106). //On grain merchants: Tooke, *History of Prices*^[42]; for Greece: Böckh, *Staatshaushalt der Athener*, I, 1, § 15; for Rome: Jhering, *Geist*, p. 238.^[43] *Increased mortality among the lower strata of the population* nowadays with every slight rise in prices, “*certainly a proof how little the average wage of the mass of the working classes exceeds the amount absolutely essential for life*” (p. 106, Note 19). “*Improvements in means of communication*” //“at the same time,” he adds in Note 20, “the most important condition for a speculative grain trade able to level out prices”//, *changes in cultivation methods* //“*crop rotation economy*,” by means of “the cultivation of various products which are favoured or handicapped differently by varying weather conditions”//; “hence *smaller fluctuations in grain prices within shorter periods of time* compared with “the Middle Ages and antiquity.” But fluctuations still very great even now (see Note 22, p. 107; *facts* *ibid.*).

2. *Changes in technology. New production methods.* Bessemer steel in place of iron, etc., p. 107 (cf. Note 23). Introduction of machines instead of manual labour.

3. Changes in the means of communication and transport, influencing the spatial movement of men and goods. Thereby in particular

... the *value of land* and the articles of *low specific value* affected; whole branches of production compelled to make a difficult transition to other working methods (p. 107).

//In addition Note 24, ib. The *increase in land value in the vicinity of good communications*, on account of the better sales of products made there; *the facilitation of population concentration* in towns, hence *enormous rise in value of urban land* and *land-value* in the vicinity of such places. Transport made easier from areas with *hitherto low* prices for grain and other agricultural and forestry raw materials, mining products to areas with higher prices; the result being a deterioration of the economic situation for all elements of the population with a more stable income in the former^[44] areas, and on the other hand the favouring of the producers and particularly the landowners in the same places. The easier transport (import!) of grain and other substances of low specific value has the reverse effect. Favours the consumers but prejudicial to the producers in the country of origin; necessitating a transition to other kinds of production, as in England from grain cultivation to stockraising in the forties, as a result of the competition from cheap East European corn in Germany. Difficult situation for German farmers (first) owing to the climate, then owing to the recent large wage increases, which they are not able to add on to the products as easily as the industrialists, and so on.//

4. *Changes in taste! Fashions*, etc., often occurring rapidly in a short space of time.

5. *Political changes* in the sphere of national and international commerce (war, revolution, etc.); insofar as *confidence and lack of confidence* [become] *more and more important* with increasing division of labour, the extension of international etc., commerce, the role of the credit factor, the monstrous dimensions of modern warfare, etc. (p. 108).

6. *Changes in agricultural, business and trade policy* (example: Reform of the British Corn Laws).

7. *Changes in the geographic distribution and overall economic situation of the whole population*, such as migration from the country into the towns (pp. 108, 109).

8. *Changes in the social and economic situation of individual strata of the population*, such as through granting the freedom of coalition, etc. (p. 109). //The French 5 milliards, Note 29, ib.//

Costs in the individual enterprise. In the “value” producing “labour,” in which all costs resolve themselves, “labour” in the proper *broad* sense, in particular, must also be included, whereby it “embraces *everything* which is

necessary by way of purposeful human activities for the creation of revenues,” hence particularly “the *intellectual labour* of the leader and the activity whereby capital is created and employed,” “therefore” the “*capital gain*” financing this activity also belongs to the “constitutive elements of costs.” “This view stands in contradiction to the socialist theory of value and costs and critique of capital” (p. 111).

The obscure man falsely attributes to me the view that “the *surplus-value* produced by the workers *alone* remains, in an unwarranted manner, in the hands of the capitalist entrepreneurs” (Note 3, p. 114). In fact I say the exact opposite: that the production of commodities must necessarily become “capitalist” production of commodities at a certain point, and that according to the *law of value* governing it, the “surplus-value” rightfully belongs to the capitalist and not the worker. Instead of engaging in such sophistry, the academic socialist character of the *vir obscurus* proves itself with the following banality, that the

“Uncompromising opponents of the socialists” “overlook the numerous actual *cases of exploitative relations* in which net profits are *not* properly” (!) “distributed, and the individual enterprise production costs of the companies are reduced far too much to the detriment of the workers (including the lenders of capital) and to the advantage of the employers” (l.c.).

National income in England and France (p. 120, χ – ϕ).

The annual gross income of a nation:

1. Sum total of goods *newly* produced that year. *Domestic raw materials* being included entirely according to their value; the *articles manufactured out of these and out of foreign materials* //to avoid a double assessment of raw products// at the *amount of increase in value attained by manufacturing labour*; *raw materials and semimanufactured goods sold and transported in trade*, at the amount of the increase in value effected thereby.

2. *Import of money and commodities from abroad* in the form of interest from the *claims* of the country *arising from credit business*, or from *capital investments* by home nationals abroad.

3. *Freightage* actually paid to *domestic shipping companies* by means of the import of foreign goods *during the course of foreign trade and transit-trade*.

4. *Cash or commodities imported from abroad in the form of remittances to aliens staying in the country.*

5. *The import of nonrepayable gifts, such as permanent tributes to the country from abroad, or continuing immigration and consequent regular immigration wealth.*

6. *Value surplus from the import of commodities and money resulting from international^[45] trade //but then deduct, 2. export abroad//.*

7. *Sum value of revenue from useful wealth (as from dwellinghouses, etc.)* (pp. 121, 122).

For the *net income* deduct, among other things, the “export of goods in payment for the *freightage of foreign shipping companies*” (p. 123). //The matter is not so simple: *the price of production (domestic) + freight = selling price*. If the country exports its own commodities in its own ships, then the foreign country pays the freight charges, if the market price prevailing there, etc.//

“Besides permanent tributes, regular payments to *foreign subjects abroad* (bribes and retainers, as paid by Persia to Greeks, *payments to foreign scholars* under Louis XIV, St. Peter’s Money) must be taken into account” (p. 123, Note 9).

Why not the *subsidies* which the German princes regularly used to receive from France and England?

Vid. the naive sorts of *income components of private individuals* consisting of “services performed by state and church” (p. 125, Note 14).

Individual and national assessment of value.

The destruction of a part of a stock of goods in order to sell the rest at a higher price is called by Cournot, *Recherches sur les principes mathématiques de la théorie des richesses*, 1838, “une véritable création de richesse dans le sens commercial du mot”^[46] (p. 127, Note 3).

Cf. as regards the decline of private individuals’ consumption *supplies*, or, as Wagner terms it, of their “*useful capital*” in our cultural period, in Berlin in particular, p. 128, Note 5, p. 129, Notes 8 and 10; in addition, too little money or *working capital* proper in the *production enterprise* itself, p. 130 and *ibid.*, Note 11.

Comparatively greater importance of foreign trade nowadays, p. 131, Note 13, p. 132, Note 3.

PUBLISHER'S PREFACE

In the Preface to "The Eastern Question," by Karl Marx, published in 1897, the Editors, Eleanor Marx Aveling and Edward Aveling, referred to two series of papers entitled "The Story of the Life of Lord Palmerston," and "Secret Diplomatic History of the Eighteenth Century," which they promised to publish at an early date.

Mrs. Aveling did not live long enough to see these papers through the press, but she left them in such a forward state, and we have had so many inquiries about them since, that we venture to issue them without Mrs. Aveling's final revision in two shilling pamphlets.

THE PUBLISHERS.

CHAPTER I

No. 1. Mr. Rondeau to Horace Walpole.

“Petersburg, *17th August, 1736.*

“ ... I heartily wish ... that the Turks could be brought to condescend to make the first step, for this Court seems resolved to hearken to nothing till that is done, to mortify the Porte, that has on all occasions spoken of the Russians with the greatest contempt, which the Czarina and her present Ministers cannot bear. Instead of being obliged to Sir Everard Fawkner and Mr. Thalman (the former the British, the latter the Dutch Ambassador at Constantinople), for informing them of the good dispositions of the Turks, Count Oestermann will not be persuaded that the Porte is sincere, and seemed very much surprised that they had written to them (the Russian Cabinet) without order of the King and the States-General, or without being desired by the Grand Vizier, and that their letter had not been concerted with the Emperor’s Minister at Constantinople.... I have shown Count Biron and Count Oestermann the two letters the Grand Vizier has written to the King, and at the same time told these gentlemen that as there was in them several hard reflections on this Court, I should not have communicated them if they had not been so desirous to see them. Count Biron said that was nothing, for they were used to be treated in this manner by the Turks. I desired their Excellencies not to let the Porte know that they had seen these letters, which would sooner aggravate matters than contribute to make them up....”

No. 2. Sir George Macartney to the Earl of Sandwich.

“St. Petersburg, *1st (12th) March, 1765.*

“Most Secret.

“ ... Yesterday M. Panin and the Vice-Chancellor, together with M. Osten, the Danish Minister, signed a treaty of alliance between this Court and that of Copenhagen. By one of the articles, a war with Turkey is made a *casus fœderis*; and whenever that event happens, Denmark binds herself to pay Russia a subsidy of 500,000 roubles per annum, by quarterly payments. Denmark also, by a most secret article, promises to disengage herself from all French connections, demanding only a limited time to endeavour to

obtain the arrears due to her by the Court of France. At all events, she is immediately to enter into all the views of Russia in Sweden, and to act entirely, though not openly, with her in that kingdom. Either I am deceived or M. Gross has misunderstood his instructions, when he told your lordship that Russia intended to stop short, and leave all the burden of Sweden upon England. However desirous this Court may be that we should pay a large proportion of every pecuniary engagement, yet, I am assured, she will always choose to take the lead at Stockholm. Her design, her ardent wish, is to make a common cause with England and Denmark, for the total annihilation of the French interest there. This certainly cannot be done without a considerable expense; but Russia, at present, does not seem unreasonable enough to expect that WE SHOULD PAY THE WHOLE. It has been hinted to me that £1,500 per annum, on our part, would be sufficient to support our interest, and absolutely prevent the French from ever getting at Stockholm again.

“The Swedes, highly sensible of, and very much mortified at, the dependent situation they have been in for many years, are extremely jealous of every Power that intermeddles in their affairs, and particularly so of their neighbours the Russians. This is the reason assigned to me for this Court’s desiring that we and they should act upon SEPARATE bottoms, still preserving between our respective Ministers a confidence without reserve. That our first care should be, not to establish a faction under the name of a Russian or of an English faction; but, as even the wisest men are imposed upon by a mere name, to endeavour to have OUR friends distinguished as the friends of liberty and independence. At present we have a superiority, and the generality of the nation is persuaded how very ruinous their French connections have been, and, if continued, how very destructive they will be of their true interests. M. Panin does by no means desire that the smallest change should be made in the constitution of Sweden. He wishes that the royal authority might be preserved without being augmented, and that the privileges of the people should be continued without violation. He was not, however, without his fears of the ambitious and intriguing spirit of the Queen, but the great ministerial vigilance of Count Oestermann has now entirely quieted his apprehensions on that head.

“By this new alliance with Denmark, and by the success in Sweden, which this Court has no doubt of, if properly seconded, M. Panin will, in some measure, have brought to bear his grand scheme of uniting the Powers

of the North. Nothing, then, will be wanted to render it entirely perfect, but the conclusion of a treaty alliance with Great Britain. I am persuaded this Court desires it most ardently. The Empress has expressed herself more than once, in terms that marked it strongly. Her ambition is to form, by such an union, a certain counterpoise to the family compact, and to disappoint, as much as possible, all the views of the Courts of Vienna and Versailles, against which she is irritated with uncommon resentment. I am not, however, to conceal from your lordship that we can have no hope of any such alliance, unless we agree, by some secret article, to pay a subsidy in case of a Turkish war, for no money will be desired from us, except upon an emergency of that nature. I flatter myself I have persuaded this Court of the unreasonableness of expecting any subsidy in time of peace, and that an alliance upon an equal footing will be more safe and more honourable for both nations. I can assure your lordship that a Turkish war's being a *casus fœderis*, inserted either in the body of the treaty or in a secret article, will be a *sine quâ non* in every negotiation we may have to open with this Court. The obstinacy of M. Panin upon that point is owing to the accident I am going to mention. When the treaty between the Emperor and the King of Prussia was in agitation, the Count Bestoucheff, who is a mortal enemy to the latter, proposed the Turkish clause, persuaded that the King of Prussia would never submit to it, and flattering himself with the hopes of blowing up that negotiation by his refusal. But this old politician, it seemed, was mistaken in his conjecture, for his Majesty immediately consented to the proposal on condition that Russia should make no alliance with any other Power but on the same terms. This is the real fact, and to confirm it, a few days since, Count Solme, the Prussian Minister, came to visit me, and told me that if this Court had any intention of concluding an alliance with ours without such a clause, he had orders to oppose it in the strongest manner. Hints have been given me that if Great Britain were less inflexible in that article, Russia will be less inflexible in the article of export duties in the Treaty of Commerce, which M. Gross told your lordship this Court would never depart from. I was assured at the same time, by a person in the highest degree of confidence with M. Panin, that if we entered upon the Treaty of Alliance the Treaty of Commerce would go on with it *passibus æquis*; that then the latter would be entirely taken out of the hands of the College of Trade, where so many cavils and altercations had been made, and would be settled only between the Minister and myself, and that he was

sure it would be concluded to our satisfaction, provided the Turkish clause was admitted into the Treaty of Alliance. I was told, also, that in case the Spaniards attacked Portugal, we might have 15,000 Russians in our pay to send upon that service. I must entreat your lordship on no account to mention to M. Gross the secret article of the Danish Treaty.... That gentleman, I am afraid, is no well-wisher to England.”

No. 3. — Sir James Harris to Lord Grantham.

“Petersburg, 16 (27 August), 1782.

“(Private.)

“ ... On my arrival here I found the Court very different from what it had been described to me. So far from any partiality to England, its bearings were entirely French. The King of Prussia (then in possession of the Empress’ ear) was exerting his influence against us. Count Panin assisted him powerfully; Lacy and Corberon, the Bourbon Ministers, were artful and intriguing; Prince Potemkin had been wrought upon by them; and the whole tribe which surrounded the Empress — the Schuwalloffs, Stroganoffs, and Chernicheffs — were what they still are, *garçons perruquiers de Paris*. Events seconded their endeavours. The assistance the French affected to afford Russia in settling its disputes with the Porte, and the two Courts being immediately after united as mediators at the Peace of Teschen, contributed not a little to reconcile them to each other. I was, therefore, not surprised that all my negotiations with Count Panin, *from February, 1778, to July, 1779*, should be unsuccessful, as he meant to prevent, not to promote, an alliance. It was in vain we made concessions to obtain it. He ever started fresh difficulties; had ever fresh obstacles ready. A very serious evil resulted, in the meanwhile, from my apparent confidence in him. He availed himself of it to convey in his reports to the Empress, not the language I employed, and the sentiments I actually expressed, but the language and sentiments he wished I should employ and express. He was equally careful to conceal her opinions and feelings from me; and while he described England to her as obstinate, and overbearing, and reserved, he described the Empress to me as displeased, disgusted, and indifferent to our concerns; and he was so convinced that, by this double misrepresentation, he had shut up every avenue of success that, at the time when I presented to him the Spanish declaration, he ventured to say to me, ministerially, ‘*That Great Britain had, by its own haughty conduct, brought down all its*

misfortunes on itself; that they were now at their height; that we must consent to any concession to obtain peace; and that we could expect neither assistance from our friends nor forbearance from our enemies.' I had temper enough not to give way to my feelings on this occasion.... I applied, without loss of time, to Prince Potemkin, and, by his means, the Empress *condescended* to see me alone at Peterhoff. I was so fortunate in this interview, as not only to efface all bad impressions she had against us, but by stating in its true light, our situation, and the inseparable interests of Great Britain and Russia, to raise in her mind a decided resolution to assist us. *This resolution she declared to me in express words.* When this transpired — and Count Panin was the first who knew it — he became my implacable and inveterate enemy. He not only thwarted by falsehoods and by a most undue exertion of his influence my public negotiations, but employed every means the lowest and most vindictive malice could suggest to depreciate and injure me personally; and from the very infamous accusations with which he charged me, had I been prone to fear, I might have apprehended the most infamous attacks at his hands. This relentless persecution still continues; it has outlived his Ministry. *Notwithstanding the positive assurances I had received from the Empress herself,* he found means, first to stagger, and afterwards to alter her resolutions. He was, indeed, very officiously assisted by his Prussian Majesty, who, at the time, was as much bent on oversetting our interest as he now seems eager to restore it. I was not, however, disheartened by this first disappointment, and, by redoubling my efforts, *I have twice more, during the course of my mission, brought the Empress to the verge (!) of standing forth our professed friend,* and, each time, my *expectations were grounded on assurances from her own mouth.* The first was when *our enemies conjured up the armed neutrality;* the other when Minorca was offered her. Although, on the first of these occasions, I found the same opposition from the same quarter I had experienced before, yet I am compelled to say that the principal cause of my failure was attributable to the very awkward manner in which we replied to the famous neutral declaration of February, 1780. As I well knew from what quarter the blow would come, I was prepared to parry it. *My opinion was: 'If England feels itself strong enough to do without Russia, let it reject at once these new-fangled doctrines; but if its situation is such as to want assistance, let it yield to the necessity of the*

hour, recognise them as far as they relate to Russia alone, and by a well-timed act of complaisance insure itself a powerful friend.' My opinion was not received; an ambiguous and trimming answer was given; *we seemed equally afraid to accept or dismiss them. I was instructed secretly to oppose, but avowedly to acquiesce in them,* and some unguarded expressions of one of its then confidential servants, made use of in speaking to Mr. Simolin, in direct contradiction to the temperate and cordial language that Minister had heard from Lord Stormont, *irritated* the Empress to the last degree, and completed the *dislike* and *bad opinion* she entertained of that Administration. Our enemies took advantage of these *circumstances....* I suggested the idea of giving up Minorca to the Empress, *because, as it was evident to me we should at the peace be compelled to make sacrifices, it seemed to me wiser to make them to our friends than to our enemies.* The idea was adopted at home in its whole extent, *and nothing could be more perfectly calculated to the meridian of this Court than the judicious instructions I received on this occasion from Lord Stormont.* Why this project failed I am still at a loss to learn. *I never knew the Empress incline so strongly to any one measure as she did to this, before I had my full powers to treat, nor was I ever more astonished than when I found her shrink from her purpose when they arrived.* I imputed it at the same time, in my own mind, to the *rooted aversion she had for our Ministry,* and her *total want of confidence in them;* but I since am more strongly disposed to believe that she consulted the Emperor (of Austria) on the subject, and that he not only prevailed on her to decline the offer, but betrayed the secret to France, and that it thus became public. I cannot otherwise account for this *rapid change of sentiment in the Empress,* particularly as *Prince Potemkin* (whatever he might be in other transactions) was certainly in this *cordial and sincere* in his support, and both from what I saw at the time, and from what has since come to my knowledge, *had its success at heart as much as myself.* You will observe, my lord, that *the idea of bringing the Empress forward as a friendly mediatrix went hand-in-hand with the proposed cession of Minorca.* As this idea has given rise to what has since followed, and involved us in all the dilemmas of the present mediation, it will be necessary for me to explain what my views then were, and to exculpate myself from the blame of having placed my Court in so embarrassing a situation, *my wish and intention was that she should be sole mediatrix*

without an adjoint; if you have perused what passed between her and me, in December, 1780, your lordship will readily perceive how very potent reasons I had to imagine she would be a friendly and even a partial one. I knew, indeed, she was unequal to the task; but I knew, too, how greatly *her vanity* would be flattered by this distinction, and was well aware that when once engaged she would persist, and be inevitably involved in our quarrel, particularly when it should appear (and appear it would) that we had *gratified* her with Minorca. The annexing to the mediation the other (Austrian) Imperial Court entirely overthrew this plan. It not only afforded her a pretence for not keeping her word, but piqued and mortified her; and it was under this impression that she made over the whole business to the colleague we had given her, and ordered her Minister at Vienna to subscribe implicitly to whatever the Court proposed. Hence all the evils which have since arisen, and hence those we at this moment experience. I myself could never be brought to believe that the Court of Vienna, as long as Prince Kaunitz directs its measures, can mean England any good or France any harm. It was not with that view that I endeavoured to promote its influence here, but because *I found that of Prussia in constant opposition to me*; and because I thought that if I could by any means smite this, I should get rid of my greatest obstacle. I was mistaken, and, by a singular fatality, the Courts of Vienna and Berlin seem never to have agreed in anything but in the disposition to prejudice us here by turns. The proposal relative to Minorca was the last attempt I made to induce the Empress to stand forth. I had exhausted my strength and resources; the freedom with which I had spoken in my last interview with her, though respectful, had *displeased*; and *from this period to the removal of the late Administration*, I have been reduced to act on the defensive.... I have had more difficulty in preventing the Empress from doing harm than I ever had in attempting to engage her to do us good. It was to prevent evil, that I inclined strongly for the acceptance of *her single mediation between us and Holland, when her Imperial Majesty first offered it*. The *extreme dissatisfaction* she expressed *at our refusal* justified my opinion; and I TOOK UPON ME, when it was proposed a second time, *to urge the necessity of its being agreed to* (ALTHOUGH I KNEW IT TO BE IN CONTRADICTION OF THE SENTIMENTS OF MY PRINCIPAL), since I firmly believed, had we again declined it, the Empress would, in a *moment of anger*, have joined the Dutch against us. As it is, *all has gone on well*; our *judicious* conduct has transferred to them the *ill-humour* she

originally was in with us, and she now is as partial to our cause as she was before partial to theirs. *Since the new Ministry in England, my road has been made smoother*; the great and new path struck out by *your predecessor, and which you, my lord, pursue*, has operated a most advantageous change in our favour upon the Continent. Nothing, indeed, but events which come home to her, will, I believe, ever induce her Imperial Majesty to take an active part; but there is now a *strong glow of friendship* in our favour; she approves our measures; she *trusts* our Ministry, and *she gives way to that predilection she certainly has for our nation*. Our enemies know and feel this; it keeps them in awe. This is a succinct but accurate sketch of what has passed at this Court from the day of my arrival at Petersburg to the present hour. Several inferences may be deduced from it. That the Empress is led by her passions, not by reason and argument; that her prejudices are very strong, easily acquired, and, when once fixed, irremovable; while, on the contrary, there is no sure road to her good opinion; that even when obtained, it is subject to perpetual fluctuation, and liable to be biassed by the most trifling incidents; that till she is fairly embarked in a plan, no assurances can be depended on; but that when once fairly embarked, she never retracts, and may be carried any length; that with very bright parts, an elevated mind, an uncommon sagacity, she wants *judgment, precision of idea, reflection, and L'ESPRIT DE COMBINAISON(!)* That her Ministers are either ignorant of, or indifferent to, the welfare of the State, and act from a passive submission to her will, or from motives of party and private interests.”

4. (Manuscript) Account of Russia during the commencement of the Reign of the Emperor Paul, drawn up by the Rev. L. K. Pitt, Chaplain to the Factory of St. Petersburg, and a near Relative of William Pitt.

Extract.

“There can scarcely exist a doubt concerning the real sentiments of the late Empress of Russia on the great points which have, within the last few years, convulsed the whole system of European politics. She certainly felt from the beginning the fatal tendency of the new principles, but was not, perhaps, displeased to see every European Power exhausting itself in a struggle which raised, in proportion to its violence, her own importance. It is more than probable that the state of the newly acquired provinces in Poland was likewise a point which had considerable influence over the

political conduct of Catherine. The fatal effects resulting from an apprehension of revolt in the late seat of conquest seem to have been felt in a very great degree by the combined Powers, who in the early period of the Revolution were so near reinstating the regular Government in France. The same dread of revolt in Poland, which divided the attention of the combined Powers and hastened their retreat, deterred likewise the late Empress of Russia from entering on the great theatre of war, until a combination of circumstances rendered the progress of the French armies a more dangerous evil than any which could possibly result to the Russian Empire from active operations.... The last words which the Empress was known to utter were addressed to her Secretary when she dismissed him on the morning on which she was seized: 'Tell Prince' (Zuboff), she said, 'to come to me at twelve, and to remind me of signing the Treaty of Alliance with England.'"

Having entered into ample considerations on the Emperor Paul's acts and extravagances, the Rev. Mr. Pitt continues as follows:

"When these considerations are impressed on the mind, the nature of the late secession from the coalition, and of the incalculable indignities offered to the Government of Great Britain, can alone be fairly estimated.... But the ties which bind her (Great Britain) to the Russian Empire are formed by nature, and inviolable. United, these nations might almost brave the united world; divided, the strength and importance of each is FUNDAMENTALLY impaired. England has reason to regret with Russia that the imperial sceptre should be thus inconsistently wielded, but it is the sovereign of Russia alone who divides the Empires."

The reverend gentleman concludes his account by the words:

"As far as human foresight can at this moment penetrate, the despair of an enraged individual seems a more probable means to terminate the present scene of oppression than any more systematic combination of measures to restore the throne of Russia to its dignity and importance."

CHAPTER II

The documents published in the first chapter extend from the reign of the Empress Ann to the commencement of the reign of the Emperor Paul, thus encompassing the greater part of the 18th century. At the end of that century it had become, as stated by the Rev. Mr. Pitt, the openly professed and orthodox dogma of English diplomacy, "*that the ties which bind Great Britain to the Russian Empire are formed by nature, and inviolable.*"

In perusing these documents, there is something that startles us even more than their contents — viz., their form. All these letters are "confidential," "private," "secret," "most secret"; but in spite of secrecy, privacy, and confidence, the English statesmen converse among each other about Russia and her rulers in a tone of awful reserve, abject servility, and cynical submission, which would strike us even in the public despatches of Russian statesmen. To conceal intrigues against foreign nations secrecy is resorted to by Russian diplomatists. The same method is adopted by English diplomatists freely to express their devotion to a foreign Court. The secret despatches of Russian diplomatists are fumigated with some equivocal perfume. It is one part the *fumée de fausseté*, as the Duke of St. Simon has it, and the other part that coquettish display of one's own superiority and cunning which stamps upon the reports of the French Secret Police their indelible character. Even the master despatches of Pozzo di Borgo are tainted with this common blot of the *littérature de mauvais lieu*. In this point the English secret despatches prove much superior. They do not affect superiority but silliness. For instance, can there be anything more silly than Mr. Rondeau informing Horace Walpole that he has betrayed to the Russian Minister the letters addressed by the Turkish Grand Vizier to the King of England, but that he had told "at the same time those gentlemen that as there were several hard reflections on the Russian Court he should not have communicated them, *if they had not been so anxious to see them,*" and then told their excellencies not to tell the Porte that they had seen them (those letters)! At first view the infamy of the act is drowned in the silliness of the man. Or, take Sir George Macartney. Can there be anything more silly than his happiness that Russia seemed "reasonable" enough not to expect that England "should pay the WHOLE EXPENSES" for Russia's

“choosing to take the lead at Stockholm”; or his “flattering himself” that he had “persuaded the Russian Court” not to be so “unreasonable” as to ask from England, in a time of peace, subsidies for a time of war against Turkey (then the ally of England); or his warning the Earl of Sandwich “not to mention” to the Russian Ambassador at London the secrets mentioned to himself by the Russian Chancellor at St. Petersburg? Or can there be anything more silly than Sir James Harris confidentially whispering into the ear of Lord Grantham that Catherine II. was devoid of “judgment, precision of idea, reflection, and *l’esprit de combinaison*”?

On the other hand, take the cool impudence with which Sir George Macartney informs his minister that because the Swedes were extremely jealous of, and mortified at, their dependence on Russia, England was directed by the Court of St. Petersburg to do its work at Stockholm, under the British colours of liberty and independence! Or Sir James Harris advising England to surrender to Russia Minorca and the right of search, and the monopoly of mediation in the affairs of the world — not in order to gain any material advantage, or even a formal engagement on the part of Russia, but only “a strong glow of friendship” from the Empress, and the transfer to France of her “ill humour.”

The secret Russian despatches proceed on the very plain line that Russia knows herself to have no common interests whatever with other nations, but that every nation must be persuaded separately to have common interests with Russia to the exclusion of every other nation. The English despatches, on the contrary, never dare so much as hint that Russia has common interests with England, but only endeavour to convince England that she has Russian interests. The English diplomatists themselves tell us that this was the single argument they pleaded, when placed face to face with Russian potentates.

If the English despatches we have laid before the public were addressed to private friends, they would only brand with infamy the ambassadors who wrote them. Secretly addressed as they are to the British Government itself, they nail it for ever to the pillory of history; and, instinctively, this seems to have been felt, even by Whig writers, because none has dared to publish them.

The question naturally arises from which epoch this Russian character of English diplomacy, become traditionary in the course of the 18th century,

does date its origin. To clear up this point we must go back to the time of Peter the Great, which, consequently, will form the principal subject of our researches. We propose to enter upon this task by reprinting some English pamphlets, written at the time of Peter I., and which have either escaped the attention of modern historians, or appeared to them to merit none. However, they will suffice for refuting the prejudice common to Continental and English writers, that the designs of Russia were not understood or suspected in England until at a later, and too late, epoch; that the diplomatic relations between England and Russia were but the natural offspring of the mutual material interests of the two countries; and that, therefore, in accusing the British statesmen of the 18th century of Russianism we should commit an unpardonable hysteron-proteron. If we have shown by the English despatches that, at the time of the Empress Ann, England already betrayed her own allies to Russia, it will be seen from the pamphlets we are now about to reprint that, even before the epoch of Ann, at the very epoch of Russian ascendancy in Europe, springing up at the time of Peter I., the plans of Russia were understood, and the connivance of British statesmen at these plans was denounced by English writers.

The first pamphlet we lay before the public is called *The Northern Crisis*. It was printed in London in 1716, and relates to the intended Dano-Anglo-Russian *invasion of Skana* (Schonen).

During the year 1715 a northern alliance for the partition, not of Sweden proper, but of what we may call the Swedish Empire, had been concluded between Russia, Denmark, Poland, Prussia, and Hanover. That partition forms the first grand act of modern diplomacy — the logical premiss to the partition of Poland. The partition treaties relating to Spain have engrossed the interest of posterity because they were the forerunners of the War of Succession, and the partition of Poland drew even a larger audience because its last act was played upon a contemporary stage. However, it cannot be denied that it was the partition of the Swedish Empire which inaugurated the modern era of international policy. The partition treaty not even pretended to have a pretext, save the misfortune of its intended victim. For the first time in Europe the violation of all treaties was not only made, but proclaimed the common basis of a new treaty. Poland herself, in the drag of Russia, and personated by that commonplace of immorality, Augustus II., Elector of Saxony and King of Poland, was pushed into the foreground of the conspiracy, thus signing her own death-warrant, and not even enjoying

the privilege reserved by Polyphemus to Odysseus — to be last eaten. Charles XII. predicted her fate in the manifesto flung against King Augustus and the Czar, from his voluntary exile at Bender. The manifesto is dated January 28, 1711.

The participation in this partition treaty threw England within the orbit of Russia, towards whom, since the days of the “Glorious Revolution,” she had more and more gravitated. George I., as King of England, was bound to a defensive alliance with Sweden by the treaty of 1700. Not only as King of England, but as Elector of Hanover, he was one of the guarantees, and even of the direct parties to the treaty of Travendal, which secured to Sweden what the partition treaty intended stripping her of. Even his German electoral dignity he partly owed to that treaty. However, as Elector of Hanover he declared war against Sweden, which he waged as King of England.

In 1715 the confederates had divested Sweden of her German provinces, and to effect that end introduced the Muscovite on the German soil. In 1716 they agreed to invade Sweden Proper — to attempt an armed descent upon Schonen — the southern extremity of Sweden now constituting the districts of Malmoe and Christianstadt. Consequently Peter of Russia brought with him from Germany a Muscovite army, which was scattered over Zealand, thence to be conveyed to Schonen, under the protection of the English and Dutch fleets sent into the Baltic, on the false pretext of protecting trade and navigation. Already in 1715, when Charles XII. was besieged in Stralsund, eight English men-of-war, lent by England to Hanover, and by Hanover to Denmark, had openly reinforced the Danish navy, and even hoisted the Danish flag. In 1716 the British navy was commanded by his Czarish Majesty in person.

Everything being ready for the invasion of Schonen, there arose a difficulty from a side where it was least expected. Although the treaty stipulated only for 30,000 Muscovites, Peter, in his magnanimity, had landed 40,000 on Zealand; but now that he was to send them on the errand to Schonen, he all at once discovered that out of the 40,000 he could spare but 15,000. This declaration not only paralysed the military plan of the confederates, it seemed to threaten the security of Denmark and of Frederick IV., its king, as great part of the Muscovite army, supported by the Russian fleet, occupied Copenhagen. One of the generals of Frederick proposed suddenly to fall with the Danish cavalry upon the Muscovites and

to exterminate them, while the English men-of-war should burn the Russian fleet. Averse to any perfidy which required some greatness of will, some force of character, and some contempt of personal danger, Frederick IV. rejected the bold proposal, and limited himself to assuming an attitude of defence. He then wrote a begging letter to the Czar, intimating that he had given up his Schonen fancy, and requested the Czar to do the same and find his way home: a request the latter could not but comply with. When Peter at last left Denmark with his army, the Danish Court thought fit to communicate to the Courts of Europe a public account of the incidents and transactions which had frustrated the intended descent upon Schonen — and this document forms the starting point of *The Northern Crisis*.

In a letter addressed to Baron Görtz, dated from London, January 23, 1717, by Count Gyllenborg, there occur some passages in which the latter, the then Swedish ambassador at the Court of St. James's, seems to profess himself the author of *The Northern Crisis*, the title of which he does not, however, quote. Yet any idea of his having written that powerful pamphlet will disappear before the slightest perusal of the Count's authenticated writings, such as his letters to Görtz.

“The Northern Crisis; or Impartial Reflections on the Policies of the Czar; occasioned by Mynheer Von Stocken's Reasons for delaying the descent upon Schonen. A true copy of which is prefixed, verbally translated after the tenor of that in the German Secretary's Office in Copenhagen, October 10, 1716. London, 1716.

1. — *Preface* — ... 'Tis (the present pamphlet) not fit for lawyers' clerks, but it is highly convenient to be read by those who are proper students in the laws of nations; 'twill be but lost time for any stock-jobbing, trifling dealer in Exchange-Alley to look beyond the preface on't, but every merchant in England (more especially those who trade to the Baltic) will find his account in it. The Dutch (as the courants and postboys have more than once told us) are about to mend their hands, if they can, in several articles of trade with the Czar, and they have been a long time about it to little purpose. Inasmuch as they are such a frugal people, they are good examples for the imitation of our traders; but if we can outdo them for once, in the means of projecting a better and more expeditious footing to go upon, for the emolument of us both, let us, for once, be wise enough to set the example, and let them, for once, be our imitators. This little treatise will show a pretty plain way how we may do it, as to our trade in the Baltic, at

this juncture. I desire no little *coffee-house politician* to meddle with it; but to give him even a disrelish for my company. I must let him know that he is not fit for mine. Those who are even proficient in state science, will find in it matter highly fit to employ all their powers of speculation, which they ever before past negligently by, and thought (too cursorily) were not worth the regarding. No outrageous party-man will find it at all for his purpose; but every *honest Whig* and every *honest Tory* may each of them read it, not only without either of their disgusts, but with the satisfaction of them both.... 'Tis not fit, in fine, for a mad, hectoring, Presbyterian Whig, or a raving, fretful, dissatisfied, Jacobite Tory."

2. — The reasons handed about by Mynheer Von Stocken for delaying the descent upon Schonen.

"There being no doubt, but most courts will be surprised that the descent upon Schonen has not been put into execution, notwithstanding the great preparations made for that purpose; and that all his Czarish Majesty's troops, who were in Germany, were transported to Zealand, not without great trouble and danger, partly by his own gallies, and partly by his Danish Majesty's and other vessels; and that the said descent is deferred till another time. His Danish Majesty hath therefore, in order to clear himself of all imputation and reproach, thought fit to order, that the following true account of this affair should be given to all impartial persons. Since the Swedes were entirely driven out of their *German* dominions, there was, according to all the rules of policy, and reasons of war, no other way left, than vigorously to attack the still obstinate King of Sweden, in the very heart of his country; thereby, with God's assistance, to force him to a lasting, good and advantageous peace for the allies. The King of Denmark and his Czarish Majesty were both of this opinion, and did, in order to put so good a design in execution, agree upon an interview, which at last (notwithstanding his Danish Majesty's presence, upon the account of Norway's being invaded, was most necessary in his own capital, and that the Muscovite ambassador, M. Dolgorouky, had given quite other assurances) was held at Ham and Horn, near Hamburgh, after his Danish Majesty had stayed there six weeks for the Czar. In this conference it was, on the 3rd of June, agreed between both their Majesties, after several debates, that the descent upon Schonen should positively be undertaken this year, and everything relating to the forwarding the same was entirely consented to. Hereupon his Danish Majesty made all haste for his return to

his dominions, and gave orders to work day and night to get his fleet ready to put to sea. The transport ships were also gathered from all parts of his dominions, both with inexpressible charges and great prejudice to his subjects' trade. Thus, his Majesty (as the Czar himself upon his arrival at Copenhagen owned) did his utmost to provide all necessaries, and to forward the descent, upon whose success everything depended. It happened, however, in the meanwhile, and before the descent was agreed upon in the conference at Ham and Horn, that his Danish Majesty was obliged to secure his invaded and much oppressed kingdom of Norway, by sending thither a considerable squadron out of his fleet, under the command of Vice-Admiral Gabel, which squadron could not be recalled before the enemy had left that kingdom, without endangering a great part thereof; so that out of necessity the said Vice-Admiral was forced to tarry there till the 12th of July, when his Danish Majesty sent him express orders to return with all possible speed, wind and weather permitting; but this blowing for some time contrary, he was detained.... The Swedes were all the while powerful at sea, and his Czarish Majesty himself did not think it advisable that the remainder of the Danish, in conjunction with the men-of-war then at Copenhagen, should go to convoy the Russian troops from Rostock, before the above-mentioned squadron under Vice-Admiral Gabel was arrived. This happening at last in the month of August, the confederate fleet put to sea; and the transporting of the said troops hither to Zealand was put in execution, though with a great deal of trouble and danger, but it took up so much time that the descent could not be ready till September following. Now, when all these preparations, as well for the descent as the embarking the armies, were entirely ready, his Danish Majesty assured himself that the descent should be made within a few days, at farthest by the 21st of September. The Russian Generals and Ministers first raised some difficulties to those of Denmark, and afterwards, on the 17th September, declared in an appointed conference, that his Czarish Majesty, considering the present situation of affairs, was of opinion that neither forage nor provision could be had in Schonen, and that consequently the descent was not advisable to be attempted this year, but ought to be put off till next spring. It may easily be imagined how much his Danish Majesty was surprised at this; especially seeing the Czar, if he had altered his opinion, as to this design so solemnly concerted, might have declared it sooner, and thereby saved his Danish Majesty several tons of gold, spent upon the

necessary preparations. His Danish Majesty did, however, in a letter dated the 20th of September, amply represent to the Czar, that although the season was very much advanced, the descent might, nevertheless, easily be undertaken with such a superior force, as to get a footing in Schonen, where being assured there had been a very plentiful harvest, he did not doubt but subsistence might be found; besides, that having an open communication with his own countries, it might easily be transported from thence. His Danish Majesty alleged also several weighty reasons why the descent was either to be made this year, or the thoughts of making it next spring entirely be laid aside. *Nor did he alone make these moving remonstrances to the Czar*; but his British Majesty's Minister residing here, as well as Admiral Norris, *seconded the same also in a very pressing manner*; and by express order of the King, their master, *endeavoured to bring the Czar into their opinion, and to persuade him to go on with the descent*; but his Czarish Majesty declared by his answer, that he would adhere to the resolution that he had once taken concerning this delay of making the descent; but if his Danish Majesty was resolved to venture on the descent, that he then, according to the treaty made near Straelsund, would assist him only with the 15 battalions and 1,000 horse therein stipulated; that next spring he would comply with everything else, and neither could or would declare himself farther in this affair. Since then, his Danish Majesty could not, without running so great a hazard, undertake so great a work alone with his own army and the said 15 battalions; he desired, in another letter of the 23rd September, his Czarish Majesty would be pleased to add 13 battalions of his troops, in which case his Danish Majesty would still this year attempt the descent; but even this could not be obtained from his Czarish Majesty, who absolutely refused it by his ambassador on the 24th ditto: whereupon his Danish Majesty, in his letter of the 26th, declared to the Czar, that since things stood thus, he desired none of his troops, but that they might be all speedily transported out of his dominions; that so the transport, whose freight stood him in 40,000 rix dollars per month, might be discharged, and his subjects eased of the intolerable contributions they now underwent. This he could not do less than agree to; and accordingly, all the Russian troops are already embarked, and intend for certain to go from here with the first favourable wind. It must be left to Providence and time, to discover what may have induced the Czar to a resolution so prejudicial to the Northern Alliance, and most advantageous to the common enemy.

If we would take a true survey of men, and lay them open in a proper light to the eye of our intellects, *we must first consider their natures* and then *their ends*; and by this method of examination, though their conduct is, seemingly, full of intricate mazes and perplexities, and winding round with infinite meanders of state-craft, we shall be able to dive into the deepest recesses, make our way through the most puzzling labyrinths, and at length come to the most abstruse means of bringing about the master secrets of their minds, and to unriddle their utmost mysteries.... The Czar ... is, by nature, of a great and enterprising spirit, and of a genius thoroughly politic; and as for his ends, the manner of his own Government, where he sways arbitrary lord over the estates and honours of his people, must make him, if all the policies in the world could by far-distant aims promise him accession and accumulation of empire and wealth, be everlastingly laying schemes for the achieving of both with the extremest cupidity and ambition. Whatever ends an insatiate desire of opulency, and a boundless thirst for dominion, can ever put him upon, to satisfy their craving and voracious appetites, those must, most undoubtedly, be his.

The next questions we are to put to ourselves are these three:

1. By what means can he gain these ends?
2. How far from him, and in what place, can these ends be best obtained?
3. And by what time, using all proper methods and succeeding in them, may he obtain these ends?

The possessions of the Czar were prodigious, vast in extent; the people all at his nod, all his downright arrant slaves, and all the wealth of the country his own at a word's command. But then the country, though large in ground, was not quite so in produce. Every vassal had his gun, and was to be a soldier upon call; but there was never a soldier among them, nor a man that understood the calling; and though he had all their wealth, they had no commerce of consequence, and little ready money; and consequently his treasury, when he had amassed all he could, very bare and empty. He was then but in an indifferent condition to satisfy those two natural appetites, when he had neither wealth to support a soldiery, nor a soldiery trained in the art of war. The first token this Prince gave of an aspiring genius, and of an ambition that is noble and necessary in a monarch who has a mind to flourish, was to believe none of his subjects more wise than himself, or more fit to govern. He did so, and looked upon his own proper person as the most fit to travel out among the other realms of the world and study politics

for the advancing of his dominions. He then seldom pretended to any warlike dispositions against those who were instructed in the science of arms; his military dealings lay mostly with the Turks and Tartars, who, as they had numbers as well as he, had them likewise composed, as well as his, of a rude, uncultivated mob, and they appeared in the field like a raw, undisciplined militia. In this his Christian neighbours liked him well, insomuch as he was a kind of stay or stopgap to the infidels. But when he came to look into the more polished parts of the Christian world, he set out towards it, from the very threshold, like a natural-born politician. He was not for learning the game by trying chances and venturing losses in the field so soon; no, he went upon the maxim *that it was, at that time of day, expedient and necessary for him to carry, like Samson, his strength in his head, and not in his arms*. He had then, he knew, but very few commodious places for commerce of his own, and those all situated in the *White Sea*, too remote, frozen up the most part of the year, and not at all fit for a fleet of men-of-war; but he knew of many more commodious ones of his neighbours in the Baltic, and within his reach whenever he could strengthen his hands to lay hold of them. He had a longing eye towards them; but with prudence seemingly turned his head another way, and secretly entertained the pleasant thought that he should come at them all in good time. Not to give any jealousy, he endeavours for no help from his neighbours to instruct his men in arms. That was like asking a skilful person, one intended to fight a duel with, to teach him first how to fence. *He went over to Great Britain*, where he knew that potent kingdom could, as yet, have no jealousies of his growth of power, and in the eye of which his vast extent of nation lay neglected and unconsidered and overlooked, as I am afraid it is to this very day. He was present at all our exercises, looked into all our laws, inspected our military, civil, and ecclesiastical regimen of affairs; yet this was the least he then wanted; this was the slightest part of his errand. But by degrees, when he grew familiar with our people, he visited our docks, pretending not to have any prospect of profit, but only to take a huge delight (the effect of curiosity only) to see our manner of building ships. He kept his court, as one may say, in our shipyard, so industrious was he in affording them his continual Czarish presence, and to his immortal glory for art and industry be it spoken, that the great Czar, by stooping often to the employ, could handle an axe with the best artificer of them all; and the monarch having a good mathematical head of his own, grew in some time a

very expert royal shipwright. A ship or two for his diversion made and sent him, and then two or three more, and after that two or three more, would signify just nothing at all, if they were granted to be sold to him by the *Maritime Powers*, that could, at will, lord it over the sea. It would be a puny inconsiderable matter, and not worth the regarding. Well, but then, over and above this, he had artfully insinuated himself into the goodwill of many of our best workmen, and won their hearts by his good-natured familiarities and condescension among them. To turn this to his service, he offered many very large premiums and advantages to go and settle in his country, which they gladly accepted of. A little after he sends over some private ministers and officers to negotiate for more workmen, for land officers, and likewise for picked and chosen good seamen, who might be advanced and promoted to offices by going there. Nay, even to this day, any expert seaman that is upon our traffic to the port of Archangel, if he has the least spark of ambition and any ardent desire to be in office, he need but offer himself to the sea-service of the Czar, and he is a lieutenant immediately. Over and above this, that Prince has even found the way to take by force into his service out of our merchant ships as many of their ablest seamen as he pleased, giving the masters the same number of raw Muscovites in their place, whom they afterwards were forced in their own defence to make fit for their own use. Neither is this all; he had, during the last war, many hundreds of his subjects, both noblemen and common sailors, on board *ours, the French and the Dutch fleets*; and he has all along maintained, and still maintains numbers of them in *ours and the Dutch yards*.

But seeing he looked all along upon all these endeavours towards improving himself and his subjects as superfluous, whilst a seaport was wanting, where he might build a fleet of his own, and from whence he might himself export the products of his country, and import those of others; and finding the King of Sweden possessed of the most convenient ones, I mean Narva and Revel, which he knew that Prince never could nor would amicably part with, he at last resolved to wrest them out of his hands by force. His *Swedish Majesty's* tender youth seemed the fittest time for this enterprise, but even then he would not run the hazard alone. He drew in other princes to divide the spoil with him. And the *Kings of Denmark and Poland* were weak enough to serve as instruments to forward the great and ambitious views of the Czar. It is true, he met with a mighty hard rub at his very first setting out; his whole army being entirely defeated by a handful of

Swedes at Narva. But it was his good luck that his Swedish Majesty, instead of improving so great a victory against him, turned immediately his arms against the King of Poland, against whom he was personally piqued, and that so much the more, inasmuch as he had taken that Prince for one of his best friends, and was just upon the point of concluding with him the strictest alliance when he unexpectedly invaded the Swedish Livonia, and besieged Riga. This was, in all respects, what the Czar could most have wished for; and foreseeing that the longer the war in Poland lasted, the more time should he have both to retrieve his first loss, and to gain Narva, he took care it should be spun out to as great a length as possible; for which end he never sent the King of Poland succour enough to make him too strong for the King of Sweden; who, on the other hand, though he gained one signal victory after the other, yet never could subdue his enemy as long as he received continual reinforcements from his hereditary country. And had not his Swedish Majesty, contrary to most people's expectations, marched directly into Saxony itself, and thereby forced the King of Poland to peace, the Czar would have had leisure enough in all conscience to bring his designs to greater maturity. This peace was one of the greatest disappointments the Czar ever met with, whereby he became singly engaged in the war. He had, however, the comfort of having beforehand taken *Narva*, and laid a foundation to his favourite town *Petersburg*, and to the seaport, the docks, and the vast magazines there; all which works, to what perfection they are now brought, let them tell who, with surprise, have seen them.

He (Peter) used all endeavours to bring matters to an accommodation. He proffered very advantageous conditions; *Petersburg* only, a trifle as he pretended, which he had set his heart upon, he would retain; and even for that he was willing some other way to give satisfaction. But the King of Sweden was too well acquainted with the importance of that place to leave it in the hands of an ambitious prince, and thereby to give him an inlet into the Baltic. This was the only time since the defeat at Narva that the Czar's arms had no other end than that of self-defence. They might, perhaps, even have fallen short therein, had not the King of Sweden (through whose persuasion is still a mystery), instead of marching the shortest way to Novgorod and to Moscow, turned towards Ukrain, where his army, after great losses and sufferings, was at last entirely defeated at Pultowa. As this was a fatal period to the Swedish successes, so how great a deliverance it

was to the Muscovites, may be gathered from the Czar's celebrating every year, with great solemnity, the anniversary of that day, from which his ambitious thoughts began to soar still higher. The whole of *Livonia*, *Estland*, and the best and greatest part of *Finland* was now what he demanded, after which, though he might for the present condescend to give peace to the remaining part of Sweden, he knew he could easily even add that to his conquests whenever he pleased. The only obstacle he had to fear in these his projects was from his northern neighbours; but as the *Maritime Powers*, and even the neighbouring princes in Germany, were then so intent upon their war against France, that they seemed entirely neglectful of that of the North, so there remained only Denmark and Poland to be jealous of. The former of these kingdoms had, ever since King William, of glorious memory, compelled it to make peace with Holstein and, consequently, with Sweden, enjoyed an uninterrupted tranquillity, during which it had time, by a free trade and considerable subsidies from the maritime powers to enrich itself, and was in a condition, by joining itself to Sweden, as it was its interest to do, to stop the Czar's progresses, and timely to prevent its own danger from them. The other, I mean Poland, was now quietly under the government of King Stanislaus, who, owing in a manner his crown to the King of Sweden, could not, out of gratitude, as well as real concern for the interest of his country, fail opposing the designs of a too aspiring neighbour. The Czar was too cunning not to find out a remedy for all this: he represented to the King of Denmark how low the King of Sweden was now brought, and how fair an opportunity he had, during that Prince's long absence, to clip entirely his wings, and to aggrandize himself at his expense. In King Augustus he raised the long-hid resentment for the loss of the Polish Crown, which he told him he might now recover without the least difficulty. Thus both these Princes were immediately caught. The Danes declared war against Sweden without so much as a tolerable pretence, and made a descent upon Schonen, where they were soundly beaten for their pains. King Augustus re-entered Poland, where everything has ever since continued in the greatest disorder, and *that in a great measure owing to Muscovite intrigues*. It happened, indeed, that these new confederates, whom the Czar had only drawn in to serve his ambition, became at first more necessary to his preservation than he had thought; for the Turks having declared a war against him, they hindered the Swedish arms from joining with them to attack him; but that storm being soon over, through the

Czar's wise behaviour and the avarice and folly of the Grand Vizier, he then made the intended use both of these his friends, as well as of them he afterwards, through hopes of gain, persuaded into his alliance, which was to lay all the burthen and hazard of the war upon them, in order entirely to weaken them, together with Sweden, whilst *he was preparing himself to swallow the one after the other*. He has put them on one difficult attempt after the other; their armies have been considerably lessened by battles and long sieges, whilst his own were either employed in easier conquests, and more profitable to him, or kept at the vast expense of neutral princes — near enough at hand to come up to demand a share of the booty without having struck a blow in getting it. His behaviour has been as cunning at sea, where his fleet has always kept out of harm's way and at a great distance whenever there was any likelihood of an engagement between the Danes and the Swedes. He hoped that when these two nations had ruined one another's fleets, his might then ride master in the Baltic. All this while he had taken care to make his men improve, by the example of foreigners and under their command, in the art of war.... His fleets will soon considerably outnumber the Swedish and the Danish ones joined together. He need not fear their being a hindrance from his giving a finishing stroke to this great and glorious undertaking. Which done, *let us look to ourselves; he will then most certainly become our rival, and as dangerous to us as he is now neglected*. We then may, perhaps, though too late, call to mind what our own ministers and merchants have told us of his designs of carrying on alone all the northern trade, and of getting all that from Turkey and Persia into his hands through the rivers which he is joining and making navigable from the Caspian, or the Black Sea, to his Petersburg. *We shall then wonder at our blindness that we did not suspect his designs* when we heard the prodigious works he has done at Petersburg and Revel; of which last place, the *Daily Courant*, dated November 23, says:

“Hague, Nov. 17.

“The captains of the men-of-war of the States, who have been at Revel, advise that the Czar has put that port and the fortifications of the place into such a condition of defence that it may pass for one of the most considerable fortresses, not only of the Baltic, but even of Europe.”

Leave we him now, as to his sea affairs, commerce and manufactures, and other works both of his policy and power, and let us view him in regard to his proceedings in this last campaign, especially as to that so much talked

of descent, he, in conjunction with his allies, was to make upon Schonen, and we shall find that even therein he has acted with his usual cunning. There is no doubt but the King of Denmark was the first that proposed this descent. He found that nothing but a speedy end to a war he had so rashly and unjustly begun, could save his country from ruin and from the bold attempts of the King of Sweden, either against Norway, or against Zealand and Copenhagen. To treat separately with that prince was a thing he could not do, as foreseeing that he would not part with an inch of ground to so unfair an enemy; and he was afraid that a Congress for a general place, supposing the King of Sweden would consent to it upon the terms proposed by his enemies, would draw the negotiations out beyond what the situation of his affairs could bear. He invites, therefore, all his confederates to make a home thrust at the King of Sweden, by a descent into his country, where, having defeated him, as by the superiority of the forces to be employed in that design he hoped they should, they might force him to an immediate peace on such terms as they themselves pleased. I don't know how far the rest of his confederates came into that project; but neither the *Prussian* nor the *Hanoverian* Court appeared *openly* in that project, *and how far our English fleet, under Sir John Norris, was to have forwarded it, I have nothing to say, but leave others to judge out of the King of Denmark's own declaration:* but the Czar came readily into it. He got thereby a new pretence to carry the war one campaign more at other people's expense; to march his troops into the Empire again, and to have them quartered and maintained, first in Mecklenburg and then in Zealand. In the meantime he had his eyes upon *Wismar*, and upon a Swedish island called *Gotland*. If, by surprise, he could get the first out of the hands of his confederates, he then had a good seaport, whither to transport his troops when he pleased into *Germany*, without asking the King of *Prussia's* leave for a free passage through his territories; and if, by a sudden descent, he could dislodge the *Swedes* out of the other, he then became master of the best port in the Baltic. He miscarried, however, in both these projects; for *Wismar* was too well guarded to be surprised; and he found his confederates would not give him a helping hand towards conquering *Gotland*. After this he began to look with another eye upon the descent to be made upon Schonen. He found it equally contrary to his interest, whether it succeeded or not. For if he did, and the King was thereby forced to a general peace, he knew his interests therein would be least regarded; having already notice enough of his

confederates being ready to sacrifice them, provided they got their own terms. If he did not succeed, then, besides the loss of the flower of an army he had trained and disciplined with so much care, as he very well foresaw that the English fleet would hinder the King of Sweden from attempting anything against Denmark; so he justly feared the whole shock would fall upon him, and he be thereby forced to surrender all he had taken from Sweden. These considerations made him entirely resolved not to make one of the descent; but he did not care to declare it till as late as possible: first, that he might the longer have his troops maintained at the Danish expense; secondly, that it might be too late for the King of Denmark to demand the necessary troops from his other confederates, and to make the descent without him; and, lastly, that by putting the Dane to a vast expense in making necessary preparations, he might still weaken him more, and, therefore, make him now the more dependent on him, and hereafter a more easy prey.

Thus he very carefully dissembles his real thoughts, till just when the descent was to be made, and then he, all of a sudden, refuses joining it, and defers it till next spring, with this averment, *that he will then be as good as his word*. But mark him, as some of our newspapers tell us, under this restriction, *unless he can get an advantageous peace of Sweden*. This passage, together with the common report we now have of his treating a separate peace with the King of Sweden, is a new instance of his cunning and policy. He has there two strings to his bow, of which one must serve his turn. There is no doubt but the Czar knows that an accommodation between him and the King of Sweden must be very difficult to bring about. For as he, on the one side, should never consent to part with those seaports, for the getting of which he began this war, and which are absolutely necessary towards carrying on his great and vast designs; so the King of Sweden would look upon it as directly contrary to his interest to yield up these same seaports, if possibly he could hinder it. But then again, the Czar is so well acquainted with the great and heroic spirit of his Swedish Majesty, that he does not question his yielding, rather in point of interest than nicety of honour. From hence it is, he rightly judges, that his Swedish Majesty must be less exasperated against him who, though he began an unjust war, has very often paid dearly for it, and carried it on all along through various successes than against some confederates; that taking an opportunity of his

Swedish Majesty's misfortunes, fell upon him in an ungenerous manner, and made a partition treaty of his provinces. The Czar, still more to accommodate himself to the genius of his great enemy, unlike his confederates, who, upon all occasions, spared no reflections and even very unbecoming ones (bullying memorials and hectoring manifestoes), spoke all along with the utmost civility of his brother Charles as he calls him, maintains him to be the greatest general in Europe, and even publicly avers, he will more trust a word from him than the greatest assurances, oaths, nay, even treaties with his confederates. These kind of civilities may, perhaps, make a deeper impression upon the noble mind of the King of Sweden, and he be persuaded rather to sacrifice a real interest to a generous enemy, than to gratify, in things of less moment, those by whom he has been ill, and even inhumanly used. But if this should not succeed, the Czar is still a gainer by having made his confederates uneasy at these his separate negotiations; and as we find by the newspapers, the more solicitous to keep him ready to their confederacy, which must cost them very large proffers and promises. In the meantime he leaves the Dane and the Swede securely bound up together in war, and weakening one another as fast as they can, and he turns towards the Empire and views the Protestant Princes there; and, under many specious pretences, not only marches and counter-marches about their several territories his troops that came back from Denmark, but makes also slowly advance towards Germany those whom he has kept this great while in Poland, under pretence to help the King against his dissatisfied subjects, whose commotions all the while he was the greatest fomenter of. He considers the Emperor is in war with the Turks, and therefore has found, by too successful experience, how little his Imperial Majesty is able to show his authority in protecting the members of the Empire. His troops remain in Mecklenburg, notwithstanding their departure is highly insisted upon. His replies to all the demands on that subject are filled with such reasons as if he would give new laws to the Empire.

Now let us suppose that the King of Sweden should think it more honourable to make a peace with the Czar, and to carry the force of his resentment against his less generous enemies, what a stand will then the princes of the empire, even those that unadvisedly drew in 40,000 Muscovites, to secure the tranquillity of that empire against 10,000 or 12,000 Swedes, — I say what stand will they be able to make against him while the Emperor is already engaged in war with the Turks? and the Poles,

when they are once in peace among themselves (if after the miseries of so long a war they are in a condition to undertake anything) are by treaty obliged to join their aids against that common enemy of Christianity.

Some will say I make great and sudden rises from very small beginnings. My answer is, that I would have such an objector look back and reflect why I show him, from such a speck of entity, at his first origin, growing, through more improbable and almost insuperable difficulties, to such a bulk as he has already attained to, and *whereby, as his advocates, the Dutch themselves own, he is grown too formidable for the repose, not only of his neighbours, but of Europe in general.*

But then, again, they will say he has no pretence either to make a peace with the Swede separately from the Dane or to make war upon other princes, some of whom he is bound in alliance with. Whoever thinks these objections not answered must have considered the Czar neither as to his nature or to his ends. The Dutch own further, *that he made war against Sweden without any specious pretence.* He that made war without any specious pretence may make a peace without any specious pretence, and make a new war without any specious pretence for it too. His Imperial Majesty (of Austria), like a wise Prince, when he was obliged to make war with the Ottomans, made it, as in policy, he should, powerfully. But, in the meantime, may not the Czar, who is a wise and potent Prince too, follow the example upon the neighbouring Princes round him that are Protestants? If he should, I tremble to speak it, it is not impossible, but in this age of Christianity *the Protestant religion should, in a great measure, be abolished;* and that among the Christians, the *Greeks and Romans* may once more come to be the only Pretenders for Universal Empire. The pure possibility carries with it warning enough for the Maritime Powers, and all the other Protestant Princes, to mediate a peace for Sweden, and strengthen his arms again, without which no preparations can put them sufficiently upon their guard; and this must be done early and betimes, *before the King of Sweden, either out of despair or revenge, throws himself into the Czar's hands.* For 'tis a certain maxim (which all Princes ought, and the Czar seems at this time to observe too much for the repose of Christendom) that a wise man must not stand for ceremony, and only *turn* with opportunities. No, he must even *run* with them. For the Czar's part, I will venture to say so much in his commendation, that he will hardly suffer himself to be

overtaken that way. He seems to act just as the tide serves. There is nothing which contributes more to the making our undertakings prosperous than the taking of times and opportunities; for time carrieth with it the seasons of opportunities of business. If you let them slip, all your designs are rendered unsuccessful.

In short, things seem now come to that *crisis* that peace should as soon as possible be procured to the Swede, with such advantageous articles as are consistent with the nicety of his honour to accept, and with the safety of the Protestant interest, that he should have offered to him, which can be scarce less than all the possessions which he formerly had in the Empire. As in all other things, so in politics, a long-tried certainty must be preferred before an uncertainty, tho' grounded on ever so probable suppositions. Now can there be anything more certain, than that the provinces Sweden has had in the Empire, were given to it to make it the nearer at hand and the better able to secure the Protestant interest, which, together with the liberties of the Empire it just then had saved? Can there be anything more certain than that that kingdom has, by those means, upon all occasions, secured that said interest now near fourscore years? Can there be anything more certain than, as to his present Swedish Majesty, that I may use the words of a letter her late Majesty, Queen Anne, wrote to him (Charles XII.), and *in the time of a Whig Ministry too*, viz.: "That, as a true Prince, hero and Christian, the chief end of his endeavours has been the promotion of the fear of God among men: and that without insisting on his own particular interest."

On the other hand, is it not very uncertain whether those princes, who, by sharing among them the Swedish provinces in the Empire, are now going to set up as protectors of the Protestant interests there, exclusive of the Swedes, will be able to do it? *Denmark* is already so low, and will in all appearance be so much lower still before the end of the war, that very little assistance can be expected from it in a great many years. In *Saxony*, the prospect is but too dismal under a Popish prince, so that there remain only the two illustrious houses of Hanover and Brandenburg of all the Protestant princes, powerful enough to lead the rest. Let us therefore only make a parallel between what now happens in the Duchy of Mecklenburg, and what may happen to the Protestant interest, and we shall soon find how we may be mistaken in our reckoning. That said poor Duchy has been most miserably ruined by the Muscovite troops, and it is still so; the Electors of Brandenburg and Hanover are obliged, both as directors of the circle of

Lower Saxony, as neighbours, and Protestant Princes, to rescue a fellow state of the Empire, and a Protestant country, from so cruel an oppression of a foreign Power. But, pray, what have they done? The Elector of Brandenburg, cautious lest the Muscovites might on one side invade his electorate, and on the other side from Livonia and Poland, his kingdom of Prussia; and the Elector of Hanover having the same wise caution as to his hereditary countries, have not upon this, though very pressing occasion, thought it for their interest, to use any other means than representations. But pray with what success? The Muscovites are still in Mecklenburg, and if at last they march out of it, it will be when the country is so ruined that they cannot there subsist any longer.

It seems the King of Sweden should be restored to all that he has lost on the side of the Czar; and this appears the *joint interest of both the Maritime Powers*. This may they please to undertake: *Holland*, because it is a maxim there “that the Czar grows too great, and must not be suffered to settle in the Baltic, and that Sweden must not be abandoned”; *Great Britain*, because, if the Czar compasses his vast and prodigious views, he will, by the ruin and conquest of Sweden, become our nearer and more dreadful neighbour. Besides, we are bound to it by a treaty concluded in the year 1700, between King William and the present King of Sweden, by virtue of which King William assisted the King of Sweden, when in more powerful circumstances, with all that he desired, with great sums of money, several hundred pieces of cloth, and considerable quantities of gunpowder.

But *some Politicians (whom nothing can make jealous of the growing strength and abilities of the Czar) though they are even foxes and vulpones in the art, either will not see or pretend they cannot see* how the Czar can ever be able to make so great a progress in power as to hurt us here in our island. To them it is easy to repeat the same answer a hundred times over, if they would be so kind as to take it at last, viz., *that what has been may be again*; and that they did not see how he could reach the height of power, which he has already arrived at, after, I must confess, a very incredible manner. Let those *incredulous* people look narrowly into the *nature* and the *ends* and the *designs* of this great monarch; they will find that they are laid very deep, and that his plans carry in them a prodigious deal of prudence and foresight, and his ends are at the long run brought about by a kind of magic in policy; and will they not after that own that we ought to fear everything from him? As he desires that the designs with which he labours

may not prove abortive, so he does not assign them a certain day of their birth, but leaves them to the natural productions of fit times and occasions, like those curious artists in China, who temper the mould this day of which a vessel may be made a hundred years hence.

There is another sort of short-sighted politicians among us, who have more of cunning court intrigue and immediate statecraft in them than of true policy and concern for their country's interest. These gentlemen pin entirely their faith upon other people's sleeves; ask as to everything that is proposed to them, how it is liked at Court? what the opinion of their party is concerning it? and if the contrary party is for or against it? Hereby they rule their judgment, and it is enough for their cunning leaders to brand anything with *Whiggism* or *Jacobitism*, for to make these people, without any further inquiry into the matter, blindly espouse it or oppose it. This, it seems, is at present the case of the subject we are upon. Anything said or written in favour of Sweden and the King thereof, is immediately said to come from a *Jacobite* pen, and thus reviled and rejected, without being read or considered. Nay, I have heard gentlemen go so far as to maintain publicly, and with all the vehemence in the world, that the King of Sweden was a Roman Catholic, and that the Czar was a good Protestant. This, indeed, is one of the greatest misfortunes our country labours under, and till we begin to see with our own eyes, and inquire ourselves into the truth of things, we shall be led away, God knows whither, at last. The serving of Sweden according to our treaties and real interest has nothing to do with our party causes. Instead of seeking for and taking hold of any pretence to undo Sweden, we ought openly to assist it. Could our Protestant succession have a better friend or a bolder champion?

I shall conclude this by thus shortly recapitulating what I have said. That since the Czar has not only replied to the King of Denmark entreating the contrary, but also answered our Admiral Norris, that he would persist in his resolution to delay the descent upon Schonen, and is said by other newspapers to resolve not to make it then, if he can have peace with Sweden; every Prince, and we more particularly, ought to be jealous of his having some such design as I mention in view, and consult how to prevent them, and to clip, in time, his too aspiring wings, which cannot be effectually done, first, without the Maritime Powers please to begin to keep him in some check and awe, and 'tis to be hoped a certain potent nation, that has helped him forward, can, in some measure, bring him back, and

may then speak to this great enterpriser in the language of a countryman in Spain, who coming to an image enshrined, the first making whereof he could well remember, and not finding all the respectful usage he expected, — “You need not,” quoth he, “be so proud, for we have known you from a plum-tree.” The next only way is to restore, by a peace, to the King of Sweden what he has lost; that checks his (the Czar’s) power immediately, and on that side nothing else can. I wish it may not at last be found true, that those who have been fighting against that King have, in the main, been fighting against themselves. If the Swede ever has his dominions again, and lowers the high spirit of the Czar, still he may say by his neighbours, as an old Greek hero did, whom his countrymen constantly sent into exile whenever he had done them a service, but were forced to call him back to their aid, whenever they wanted success. “These people,” quoth he, “are always using me like the palm-tree. They will be breaking my branches continually, and yet, if there comes a storm, they run to me, and can’t find a better place for shelter.” But if he has them not, I shall only exclaim a phrase out of Terence’s “Andria”:

“Hoccine credibile est aut memorabile
Tanta vecordia innata cuiquam ut siet,
Ut malis gaudeant?”

4. Postscript. — I flatter myself that this little history is of that curious nature, and on matters hitherto so unobserved, that I consider it, with pride, as a valuable New Year’s gift to the present world; and that posterity will accept it, as the like, for many years after, and read it over on that anniversary, and call it their *Warning Piece*. I must have my *Exegi-Monumentum* as well as others.

CHAPTER III

To understand a limited historical epoch, we must step beyond its limits, and compare it with other historical epochs. To judge Governments and their acts, we must measure them by their own times and the conscience of their contemporaries. Nobody will condemn a British statesman of the 17th century for acting on a belief in witchcraft, if he find Bacon himself ranging demonology in the catalogue of science. On the other hand, if the Stanhopes, the Walpoles, the Townshends, etc., were suspected, opposed, and denounced in their own country by their own contemporaries as tools or accomplices of Russia, it will no longer do to shelter their policy behind the convenient screen of prejudice and ignorance common to their time. At the head of the historical evidence we have to sift, we place, therefore, long-forgotten English pamphlets printed at the very time of Peter I. These preliminary *pièces des procès* we shall, however, limit to three pamphlets, which, from three different points of view, illustrate the conduct of England towards Sweden. The first, the *Northern Crisis* (given in Chapter II.), revealing the general system of Russia, and the dangers accruing to England from the Russification of Sweden; the second, called *The Defensive Treaty*, judging the acts of England by the Treaty of 1700; and the third, entitled *Truth is but Truth, however it is Timed*, proving that the new-fangled schemes which magnified Russia into the paramount Power of the Baltic were in flagrant opposition to the traditionary policy England had pursued during the course of a whole century.

The pamphlet called *The Defensive Treaty* bears no date of publication. Yet in one passage it states that, for reinforcing the Danish fleet, eight English men-of-war were left at Copenhagen “*the year before the last*,” and in another passage alludes to the assembling of the confederate fleet for the Schonen expedition as having occurred “*last summer*.” As the former event took place in 1715, and the latter towards the end of the summer of 1716, it is evident that the pamphlet was written and published in the earlier part of the year 1717. The Defensive Treaty between England and Sweden, the single articles of which the pamphlet comments upon in the form of queries, was concluded in 1700 between William III. and Charles XII., and was not to expire before 1719. Yet, during almost the whole of this period, we find

England continually assisting Russia and waging war against Sweden, either by secret intrigue or open force, although the treaty was never rescinded nor war ever declared. This fact is, perhaps, even less strange than the *conspiration de silence* under which modern historians have succeeded in burying it, and among them historians by no means sparing of censure against the British Government of that time, for having, without any previous declaration of war, destroyed the Spanish fleet in the Sicilian waters. But then, at least, England was not bound to Spain by a defensive treaty. How, then, are we to explain this contrary treatment of similar cases? The piracy committed against Spain was one of the weapons which the Whig Ministers, seceding from the Cabinet in 1717, caught hold of to harass their remaining colleagues. When the latter stepped forward in 1718, and urged Parliament to declare war against Spain, Sir Robert Walpole rose from his seat in the Commons, and in a most virulent speech denounced the late ministerial acts “as contrary to the laws of nations, and a breach of solemn treaties.” “Giving sanction to them in the manner proposed,” he said, “could have no other view than to screen ministers, who were conscious of having done something amiss, and who, having begun a war against Spain, would now make it the Parliament’s war.” The treachery against Sweden and the connivance at the plans of Russia, never happening to afford the ostensible pretext for a family quarrel amongst the Whig rulers (they being rather unanimous on these points), never obtained the honours of historical criticism so lavishly spent upon the Spanish incident.

How apt modern historians generally are to receive their cue from the official tricksters themselves, is best shown by their reflections on the commercial interests of England with respect to Russia and Sweden. Nothing has been more exaggerated than the dimensions of the trade opened to Great Britain by the huge market of the Russia of Peter the Great, and his immediate successors. Statements bearing not the slightest touch of criticism have been allowed to creep from one book-shelf to another, till they became at last historical household furniture, to be inherited by every successive historian, without even the *beneficium inventarii*. Some incontrovertible statistical figures will suffice to blot out these hoary common-places.

British Commerce from 1697-1700.

£

Export to Russia	58,884
------------------	--------

Import from Russia	112,252
--------------------	---------

Total	171,136
-------	---------

Export to Sweden	57,555
------------------	--------

Import from Sweden	212,094
--------------------	---------

Total	269,649
-------	---------

During the same period the total

Export of England amounted to	£ 3,525,906
-------------------------------	-------------

Import	3,482,586
--------	-----------

Total	7,008,492
-------	-----------

In 1716, after all the Swedish provinces in the Baltic, and on the Gulfs of Finland and Bothnia, had fallen into the hands of Peter I., the

Export to Russia was	£ 113,154
----------------------	-----------

Import from Russia	197,270
--------------------	---------

Total	310,424
-------	---------

Export to Sweden	24,101
------------------	--------

Import from Sweden	136,959
--------------------	---------

Total	161,060
-------	---------

At the same time, the total of English exports and imports together reached about £10,000,000. It will be seen from these figures, when compared with those of 1697-1700, that the increase in the Russian trade is balanced by the decrease in the Swedish trade, and that what was added to the one was subtracted from the other.

In 1730, the

Export to Russia was	£ 46,275
----------------------	----------

Import from Russia	258,802
--------------------	---------

Total	305,077
-------	---------

Fifteen years, then, after the consolidation in the meanwhile of the Muscovite settlement on the Baltic, the British trade with Russia had fallen off by £5,347. The general trade of England reaching in 1730 the sum of £16,329,001, the Russian trade amounted not yet to 1/53rd of its total value. Again, thirty years later, in 1760, the account between Great Britain and Russia stands thus:

	£
Import from Russia (in 1760)	536,504
Export to Russia	39,761
Total	£576,265

while the general trade of England amounted to £26,361,760. Comparing these figures with those of 1706, we find that the total of the Russian commerce, after nearly half a century, has increased by the trifling sum of only £265,841. That England suffered positive loss by her new commercial relations with Russia under Peter I. and Catherine I. becomes evident on comparing, on the one side, the export and import figures, and on the other, the sums expended on the frequent naval expeditions to the Baltic which England undertook during the lifetime of Charles XII., in order to break down his resistance to Russia, and, after his death, on the professed necessity of checking the maritime encroachments of Russia.

Another glance at the statistical data given for the years 1697, 1700, 1716, 1730, and 1760, will show that the British *export* trade to Russia was continually falling off, save in 1716, when Russia engrossed the whole Swedish trade on the eastern coast of the Baltic and the Gulf of Bothnia, and had not yet found the opportunity of subjecting it to her own regulations. From £58,884, at which the British exports to Russia stood during 1697-1700, when Russia was still precluded from the Baltic, they had sunk to £46,275 in 1730, and to £39,761 in 1760, showing a decrease of £19,123, or about 1/3rd of their original amount in 1700. If, then, since, the absorption of the Swedish provinces by Russia, the British market proved expanding for Russia raw produce, the Russian market, on its side, proved straitening for British manufacturers, a feature of that trade which could hardly recommend it at a time when the Balance of Trade doctrine ruled

supreme. To trace the circumstances which produced the increase of the Anglo-Russian trade under Catherine II. would lead us too far from the period we are considering.

On the whole, then, we arrive at the following conclusions: During the first sixty years of the eighteenth century the total Anglo-Russian trade formed but a very diminutive fraction of the general trade of England, say less than 1/45th. Its sudden increase during the earliest years of Peter's sway over the Baltic did not at all affect the general balance of British trade, as it was a simple transfer from its Swedish account to its Russian account. In the later times of Peter I., as well as under his immediate successors, Catherine I. and Anne, the Anglo-Russian trade was positively declining; during the whole epoch, dating from the final settlement of Russia in the Baltic provinces, the export of British manufactures to Russia was continually falling off, so that at its end it stood one-third lower than at its beginning, when that trade was still confined to the port of Archangel. Neither the contemporaries of Peter I., nor the next British generation reaped any benefit from the advancement of Russia to the Baltic. In general the Baltic trade of Great Britain was at that time trifling in regard of the capital involved, but important in regard of its character. It afforded England the raw produce for its maritime stores. That from the latter point of view the Baltic was in safer keeping in the hands of Sweden than in those of Russia, was not only proved by the pamphlets we are reprinting, but fully understood by the British Ministers themselves. Stanhope writing, for instance, to Townshend on October 16th, 1716:

"It is certain that if the Czar be let alone three years, he will be absolute master in those seas."

If, then, neither the navigation nor the general commerce of England was interested in the treacherous support given to Russia against Sweden, there existed, indeed, one small fraction of British merchants whose interests were identical with the Russian ones — the Russian Trade Company. It was this gentry that raised a cry against Sweden. See, for instance:

"Several grievances of the English merchants in their trade into the dominions of the King of Sweden, whereby it does appear how dangerous it may be for the English nation to depend on Sweden only for the supply of the naval stores, when they might be amply furnished with the like stores from the dominions of the Emperor of Russia."

“The case of the merchants trading to Russia” (a petition to Parliament), etc.

It was they who in the years 1714, 1715, and 1716, regularly assembled twice a week before the opening of Parliament, to draw up in public meetings the complaints of the British merchantmen against Sweden. On this small fraction the Ministers relied; they were even busy in getting up its demonstrations, as may be seen from the letters addressed by Count Gyllenborg to Baron Görtz, dated 4th of November and 4th of December, 1716, wanting, as they did, but the shadow of a pretext to drive their “mercenary Parliament,” as Gyllenborg calls it, where they liked. The influence of these British merchants trading to Russia was again exhibited in the year 1765, and our own times have witnessed the working for his interest, of a Russian merchant at the head of the Board of Trade, and of a Chancellor of the Exchequer in the interest of a cousin engaged in the Archangel trade.

The oligarchy which, after the “glorious revolution,” usurped wealth and power at the cost of the mass of the British people, was, of course, forced to look out for allies, not only abroad, but also at home. The latter they found in what the French would call *la haute bourgeoisie*, as represented by the Bank of England, the money-lenders, State creditors, East India and other trading corporations, the great manufacturers, etc. How tenderly they managed the material interests of that class may be learned from the whole of their domestic legislation — Bank Acts, Protectionist enactments, Poor Regulations, etc. As to their *foreign policy*, they wanted to give it the appearance at least of being altogether regulated by the mercantile interest, an appearance the more easily to be produced, as the exclusive interest of one or the other small fraction of that class would, of course, be always identified with this or that Ministerial measure. The interested fraction then raised the commerce and navigation cry, which the nation stupidly re-echoed.

At that time, then, there devolved on the Cabinet, at least, the *onus* of inventing *mercantile pretexts*, however futile, for their measures of foreign policy. In our own epoch, British Ministers have thrown this burden on foreign nations, leaving to the French, the Germans, etc., the irksome task of discovering the *secret* and *hidden* mercantile springs of their actions. Lord Palmerston, for instance, takes a step apparently the most damaging to

the material interests of Great Britain. Up starts a State philosopher, on the other side of the Atlantic, or of the Channel, or in the heart of Germany, who puts his head to the rack to dig out the mysteries of the mercantile Machiavelism of “perfid Albion,” of which Palmerston is supposed the unscrupulous and unflinching executor. We will, *en passant*, show, by a few modern instances, what desperate shifts those foreigners have been driven to, who feel themselves obliged to interpret Palmerston’s acts by what they imagine to be the English commercial policy. In his valuable *Histoire Politique et Sociale des Principautés Danubiennes*, M. Elias Regnault, startled by the Russian conduct, before and during the years 1848-49 of Mr. Colquhoun, the British Consul at Bucharest, suspects that England has some secret material interest in keeping down the trade of the Principalities. The late Dr. Cunibert, private physician of old Milosh, in his most interesting account of the Russian intrigues in Servia, gives a curious relation of the manner in which Lord Palmerston, through the instrumentality of Colonel Hodges, betrayed Milosh to Russia by feigning to support him against her. Fully believing in the personal integrity of Hodges, and the patriotic zeal of Palmerston, Dr. Cunibert is found to go a step further than M. Elias Regnault. He suspects England of being interested in putting down Turkish commerce generally. General Mieroslawski, in his last work on Poland, is not very far from intimating that mercantile Machiavelism instigated England to sacrifice her own *prestige* in Asia Minor, by the surrender of Kars. As a last instance may serve the present lucubrations of the Paris papers, hunting after the secret springs of commercial jealousy, which induce Palmerston to oppose the cutting of the Isthmus of Suez canal.

To return to our subject. The mercantile pretext hit upon by the Townshends, Stanhopes, etc., for the hostile demonstrations against Sweden, was the following. Towards the end of 1713, Peter I. had ordered all the hemp and other produce of his dominions, destined for export, to be carried to St. Petersburg instead of Archangel. Then the Swedish Regency, during the absence of Charles XII., and Charles XII. himself, after his return from Bender, declared all the Baltic ports, occupied by the Russians, to be blockaded. Consequently, English ships, breaking through the blockade, were confiscated. The English Ministry then asserted that British merchantmen had the right of trading to those ports according to Article XVII. of the Defensive Treaty of 1700, by which English commerce, with the exception of contraband of war, was allowed to go on with ports of the

enemy. The absurdity and falsehood of this pretext being fully exposed in the pamphlet we are about to reprint, we will only remark that the case had been more than once decided against commercial nations, not bound, like England, by treaty to defend the integrity of the Swedish Empire. In the year 1561, when the Russians took Narva, and laboured hard to establish their commerce there, the Hanse towns, chiefly Lübeck, tried to possess themselves of this traffic. Eric XIV., then King of Sweden, resisted their pretensions. The city of Lübeck represented this resistance as altogether new, as they had carried on their commerce with the Russians time out of mind, and pleaded the common right of nations to navigate in the Baltic, provided their vessels carried no contraband of war. The King replied that he did not dispute the Hanse towns the liberty of trading with Russia, but only with Narva, which was no Russian port. In the year 1579 again, the Russians having broken the suspension of arms with Sweden, the Danes likewise claimed the navigation to Narva, by virtue of their treaty, but King John was as firm in maintaining the contrary, as was his brother Eric.

In her open demonstrations of hostility against the King of Sweden, as well as in the false pretence on which they were founded, England seemed only to follow in the track of Holland, which declaring the confiscation of its ships to be piracy, had issued two proclamations against Sweden in 1714.

In one respect, the case of the States-General was the same as that of England. King William had concluded the Defensive Treaty as well for Holland as for England. Besides, Article XVI., in the Treaty of Commerce, concluded between Holland and Sweden in 1703, expressly stipulated that no navigation ought to be allowed to the ports blocked up by either of the confederates. The then common Dutch cant that “there was no hindering traders from carrying their merchandise where they will,” was the more impudent as, during the war, ending with the Peace of Ryswick, the Dutch Republic had declared all France to be blocked up, forbidden the neutral Powers all trade with that kingdom, and caused all their ships that went there or came thence to be brought up without any regard to the nature of their cargoes.

In another respect, the situation of Holland was different from that of England. Fallen from its commercial and maritime grandeur, Holland had then already entered upon its epoch of decline. Like Genoa and Venice, when new roads of commerce had dispossessed them of their old mercantile

supremacy, it was forced to lend out to other nations its capital, grown too large for the vessels of its own commerce. Its fatherland had begun to lie there where the best interest for its capital was paid. Russia, therefore, proved an immense market, less for the commerce than for the outlay of capital and men. To this moment Holland has remained the banker of Russia. At the time of Peter they supplied Russia with ships, officers, arms, and money, so that his fleet, as a contemporary writer remarks, ought to have been called a Dutch rather than a Muscovite one. They gloried in having sent the first European merchant ship to St. Petersburg, and returned the commercial privileges they had obtained from Peter, or hoped to obtain from him, by that fawning meanness which characterizes their intercourse with Japan. Here, then, was quite another solid foundation than in England for the Russianism of statesmen, whom Peter I. had entrapped during his stay at Amsterdam, and the Hague in 1697, whom he afterwards directed by his ambassadors, and with whom he renewed his personal influence during his renewed stay at Amsterdam in 1716-17. Yet, if the paramount influence England exercised over Holland during the first *decennia* of the 18th century be considered, there can remain no doubt that the proclamations against Sweden by the States-General would never have been issued, if not with the previous consent and at the instigation of England. The intimate connection between the English and Dutch Governments served more than once the former to put up precedents in the name of Holland, which they were resolved to act upon in the name of England. On the other hand, it is no less certain that the Dutch statesmen were employed by the Czar to influence the British ones. Thus Horace Walpole, the brother of the "Father of Corruption," the brother-in-law of the Minister, Townshend, and the British Ambassador at the Hague during 1715-16, was evidently inveigled into the Russian interest by his Dutch friends. Thus, as we shall see by-and-by, Theyls, the Secretary to the Dutch Embassy at Constantinople, at the most critical period of the deadly struggle between Charles XII. and Peter I., managed affairs at the same time for the Embassies of England and Holland at the Sublime Porte. This Theyls, in a print of his, openly claims it as a merit with his nation to have been the devoted and rewarded agent of Russian intrigue.

CHAPTER IV

“The Defensive Treaty concluded in the year 1700, between his late Majesty, King William, of ever-glorious memory, and his present Swedish Majesty, King Charles XII. Published at the earnest desire of several members of both Houses of Parliament.

‘Nec rumpite fœdera pacis,
Nec regnis præferte fidem.’
— Silius, *Lip.* II.

“*Article I.* Establishes between the Kings of Sweden and England ‘a sincere and constant friendship for ever, a league and good correspondence, so that they shall never mutually or separately molest one another’s kingdoms, provinces, colonies, or subjects, wheresoever situated, *nor shall they suffer or agree that this should be done by others, etc.*’

“*Article II.* ‘Moreover, each of the Allies, his heirs and successors, shall be obliged to take care of, and promote, as much as in him lies, the profit and honour of the other, to detect and give notice to his other ally (as soon as it shall come to his own knowledge) of all imminent dangers, conspiracies, and hostile designs formed against him, to withstand them as much as possible, and to prevent them both by advice and assistance; and therefore *it shall not be lawful for either of the Allies, either by themselves or any other whatsoever, to act, treat, or endeavour anything to the prejudice or loss of the other, his lands or dominions whatsoever or wheresoever, whether by land or sea; that one shall in no wise favour the other’s foes, either rebels or enemies, to the prejudice of his Ally,*’ etc.

“*Query I.* How the words marked in italics agree with our present conduct, when our fleet acts in conjunction with the enemies of Sweden, *the Czar commands our fleet, our Admiral enters into Councils of War, and is not only privy to all their designs, but together with our own Minister at Copenhagen* (as the King of Denmark has himself owned it in a public declaration), *pushed on the Northern Confederates to an enterprise entirely destructive to our Ally Sweden, I mean the descent designed last summer upon Schonen?*

“*Query II.* In what manner we also must explain that passage in the first article by which it is stipulated that one Ally shall not either by themselves

or any other whatsoever, act, treat, or endeavour anything to the loss of the other's lands and dominions; to justify in particular our leaving in the year 1715, even when the season was so far advanced as no longer to admit of our usual pretence of conveying and protecting our trade, which was then got already safe home, eight men-of-war in the Baltic, with orders to join in one line of battle with the Danes, whereby we made them so much superior in number to the Swedish fleet, that it could not come to the relief of Straelsund, and whereby *we chiefly occasioned Sweden's entirely losing its German Provinces*, and even the *extreme danger his Swedish Majesty ran in his own person*, in crossing the sea, before the surrender of the town.

“*Article III.* By a special defensive treaty, the Kings of Sweden and England mutually oblige themselves, ‘in a strict alliance, to defend one another mutually, as well as their kingdoms, territories, provinces, states, subjects, possessions, as their rights and liberties of navigation and commerce, as well in the Northern, Deucalidonian, Western, and Britannic Sea, commonly called the Channel, the Baltic, the Sound; as also of the privileges and prerogatives of each of the Allies belonging to them, by virtue of treaties and agreements, as well as by received customs, the laws of nations, hereditary right, against any aggressors or invaders and molesters in Europe by sea or land, etc.’

“*Query.* It being by the law of nations an indisputable right and prerogative of any king or people, in case of a great necessity or threatening ruin, to use all such means they themselves shall judge most necessary for their preservation; it having moreover been a constant prerogative and practice of the Swedes, for these several hundred years, in case of a war with their most dreadful enemies the Muscovites, to hinder all trade with them in the Baltic; and since it is also stipulated in this article that amongst other things, *one Ally ought to defend the prerogatives belonging to the other, even by received customs, and the law of nations*: how come we now, the King of Sweden stands more than ever in need of using that prerogative, not only to dispute it, but also to take thereof a pretence for an open hostility against him?

“*Articles IV., V., VI., and VII.* fix the strength of the auxiliary forces England and Sweden are to send each other in case the territory of either of these powers should be invaded, or its navigation ‘molested or hindered’ in one of the seas enumerated in Article III. The invasion of the *German provinces of Sweden* is expressly included as a *casus fæderis*.

“*Article VIII.* stipulates that that Ally who is not attacked shall first act the part of a pacific mediator; but, the mediation having proved a failure, ‘the aforesaid forces shall be sent without delay; nor shall the confederates desist before the injured party shall be satisfied in all things.’

“*Article IX.* That Ally that requires the stipulated ‘help, has to choose whether he will have the above-named army either all or any, either in soldiers, ships, ammunition, or money.’

“*Article X.* Ships and armies serve under ‘the command of him that required them.’

“*Article XI.* ‘But if it should happen that the above-mentioned forces should not be proportionable to the danger, as supposing that perhaps the aggressor should be assisted by the forces of some other confederates of his, then one of the Allies, after previous request, shall be obliged to help the other that is injured, with greater forces, such as he shall be able to raise with safety and convenience, both by sea and land....’

“*Article XII.* ‘It shall be lawful for either of the Allies and their subjects to bring their men-of-war into one another’s harbours, and to winter there.’ Peculiar negotiations about this point shall take place at Stockholm, but ‘in the meanwhile, the articles of treaty concluded at London, 1661, relating to the navigation and commerce shall remain, in their full force, as much as if they were inserted here word for word.’

“*Article XIII.* ‘... The subjects of either of the Allies ... shall no way, either by sea or land, serve them (the enemies of either of the Allies), either as mariners or soldiers, and therefore it shall be forbid them upon severe penalty.’

“*Article XIV.* ‘If it happens that either of the confederate kings ... should be engaged in a war against a common enemy, or be molested by any other neighbouring king ... in his own kingdoms or provinces ... to the hindering of which, he that requires help may by the force of this treaty himself be obliged to send help: then that Ally so molested shall not be obliged to send the promised help....’

“*Query I.* Whether in our conscience we don’t think the King of Sweden most unjustly attacked by all his enemies; whether consequently we are not convinced that we owe him the assistance stipulated in these Articles; whether he has not demanded the same from us, and why it has hitherto been refused him?

“*Query II.* These articles, setting forth in the most expressing terms, in what manner Great Britain and Sweden ought to assist one another, can either of these two Allies take upon him to prescribe to the other who requires his assistance a way of lending him it not expressed in the treaty; and if that other Ally does not think it for his interest to accept of the same, but still insists upon the performance of the treaty, can he from thence take a pretence, not only to withhold the stipulated assistance, but also to use his Ally in a hostile way, and to join with his enemies against him? If this is not justifiable, as even common sense tells us it is not, how can the reason stand good, which we allege amongst others, for using the King of Sweden as we do, *id est*, that demanding a literal performance of his alliance with us, *he would not accept the treaty of neutrality for his German provinces*, which we proposed to him some years ago, a treaty which, not to mention its partiality in favour of the enemies of Sweden, and that it was calculated only for our own interest, and for to prevent all disturbance in the empire, whilst we were engaged in a war against France, the King of Sweden had so much less reason to rely upon, as he was to conclude it with those very enemies, that had every one of them broken several treaties in beginning the present war against him, and as it was to be guaranteed by those powers, who were also every one of them guarantees of the broken treaties, without having performed their guarantee?

“*Query III.* How can we make the words in the 7th Article, *that in assisting our injured Ally we shall not desist before he shall be satisfied in all things*, agree with our endeavouring, to the contrary, to help the enemies of that Prince, though all unjust aggressors, not only to take one province after the other from him, but also to remain undisturbed possessors thereof, blaming all along the King of Sweden for not tamely submitting thereunto?

“*Query IV.* The treaty concluded in the year 1661, between Great Britain and Sweden, being in the 11th Article confirmed, and the said treaty forbidding expressly one of the confederates *either himself or his subjects to lend or to sell to the other's enemies, men-of-war or ships of defence*; the 13th Article of this present treaty forbidding also expressly the subjects of either of the Allies *to help anyways the enemies of the other, to the inconvenience and loss of such an Ally*; should we not have accused the Swedes of the most notorious breach of this treaty, had they, during our late war with the French, lent them their own fleet, the better to execute any design of theirs against us, or had they, notwithstanding our representations

to the contrary, suffered their subjects to furnish the French with ships of 50, 60, and 70 guns! Now, if we turn the tables, and remember upon how many occasions our fleet has of late been entirely subservient to the designs of the enemies of Sweden, even in most critical times, and that *the Czar of Muscovy has actually above a dozen English-built ships* in his fleet, will it not be very difficult for us to excuse in ourselves what we should most certainly have blamed, if done by others?

“*Article XVII.* The obligation shall not be so far extended as that all friendship and mutual commerce with the enemies of that Ally (that requires the help) shall be taken away; for supposing that one of the confederates should send his auxiliaries, and should not be engaged in the war himself, it shall then be lawful for the subjects to trade and commerce with that enemy of that Ally that is engaged in the war, also directly and safely to merchandise with such enemies, for all goods not expressly forbid and called contraband, as in a special treaty of commerce hereafter shall be appointed.

“*Query I.* This Article being the only one out of twenty-two whose performance we have now occasion to insist upon from the Swedes, the question will be whether we ourselves, in regard to Sweden, have performed all the other articles as it was our part to do, and whether in demanding of the King of Sweden the executing of this Article, we have promised that we would also do our duty as to all the rest; if not, may not the Swedes say that we complain unjustly of the breach of one single Article, when we ourselves may perhaps be found guilty of having in the most material points either not executed or even acted against the whole treaty?

“*Query II.* Whether the liberty of commerce one Ally is, by virtue of this Article, to enjoy with the other’s enemies, ought to have no limitation at all, neither as to time nor place; in short, whether it ought even to be extended so far as to destroy the very end of this Treaty, which is the promoting the safety and security of one another’s kingdoms?

“*Query III.* Whether in case the French had in the late wars made themselves masters of Ireland or Scotland, and either in new-made seaports, or the old ones, endeavoured by trade still more firmly to establish themselves in their new conquest, we, in such a case, should have thought the Swedes our true allies and friends, had they insisted upon this Article to trade with the French in the said seaports taken from us, and to furnish them

there with several necessities of war, nay, even with armed ships, whereby the French might the easier have annoyed us here in England?

“*Query IV.* Whether, if we had gone about to hinder a trade so prejudicial to us, and in order thereunto brought up all Swedish ships going to the said seaports, we should not highly have exclaimed against the Swedes, had they taken from thence a pretence to join their fleet with the French, to occasion the losing of any of our dominions, and even to encourage the invasion upon us, have their fleet at hand to promote the same?

“*Query V.* Whether upon an impartial examination this would not have been a case exactly parallel to that we insist upon, as to a free Trade to the seaports the Czar has taken from Sweden, and to our present behaviour, upon the King of Sweden’s hindering the same?

“*Query VI.* Whether we have not ever since Oliver Cromwell’s time till 1710, in all our wars with France and Holland, without any urgent necessity at all, brought up and confiscated Swedish ships, though not going to any prohibited ports, and that to a far greater number and value, than all those the Swedes have now taken from us, and whether the Swedes have ever taken a pretence from thence to join with our enemies, and to send whole squadrons of ships to their assistance?

“*Query VII.* Whether, if we inquire narrowly into the state of commerce, as it has been carried on for these many years, we shall not find that the trade of the above-mentioned places was not so very necessary to us, at least not so far as to be put into the balance with the preservation of a Protestant confederate nation, much less to give us a just reason *to make war against that nation, which, though not declared, has done it more harm than the united efforts of all its enemies?*

“*Query VIII.* Whether, if it happened two years ago, that this trade became something more necessary to us than formerly, it is not easily proved, that it was occasioned only by the Czar’s forcing us out of our old channel of trade to Archangel, and bringing us to Petersburg, and our complying therewith. So that all the inconveniences we laboured under upon that account ought to have been laid to the Czar’s door, and not to the King of Sweden’s?

“*Query IX.* Whether the Czar did not in the very beginning of 1715 again permit us to trade our old way to Archangel, and whether our Ministers had not notice thereof a great while before our fleet was sent that year to protect

our *trade to Petersburg*, which by this alteration in the Czar's resolution was become as unnecessary for us as before?

“*Query X.* Whether the King of Sweden had not declared, that if we would forbear trading to *Petersburg*, etc., which he looked upon as ruinous to his kingdom, he would in no manner disturb our trade, neither in the Baltic nor anywhere else; but that in case we would not give him this slight proof of our friendship, he should be excused if the innocent came to suffer with the guilty?

“*Query XI.* Whether, by our insisting upon the trade to the ports prohibited by the King of Sweden, which besides it being unnecessary to us, hardly makes one part in ten of that we carry on in the Baltic, we have not drawn upon us the hazards that our trade has run all this while, been ourselves the occasion of our great expenses in fitting out fleets for its protection, and by our joining with the enemies of Sweden, fully justified his Swedish Majesty's resentment; had it ever gone so far as to seize and confiscate without distinction all our ships and effects, wheresoever he found them, either within or without his kingdoms?

“*Query XII.* If we were so tender of our trade to the northern ports in general, ought we not in policy rather to have considered the hazard that trade runs by the approaching ruin of Sweden, and *by the Czar's becoming the whole and sole master of the Baltic, and all the naval stores we want from thence?* Have we not also suffered greater hardships and losses in the said trade from the Czar, than that amounting only to sixty odd thousand pounds (whereof, by the way, two parts in three may perhaps be disputable), which provoked us first to send twenty men-of-war in the Baltic with order to attack the Swedes wherever they met them? And yet, did not this very Czar, this very aspiring and dangerous prince, *last summer command the whole confederate fleet, as it was called, of which our men-of-war made the most considerable part? The first instance that ever was of a Foreign Potentate having the command given him of the English fleet, the bulwark of our nation;* and did not our said men-of-war afterwards convey his (the Czar's) transport ships and troops on board of them, in their return from Zealand, *protecting them from the Swedish fleet,* which else would have made a considerable havoc amongst them?

“*Query XIII.* Suppose now, we had, on the contrary, taken hold of the great and many complaints our merchants have made of the ill-usage they

meet from the Czar, to have sent our fleet to show our resentment against that prince, to prevent his great and pernicious designs even to us, *to assist Sweden pursuant to this Treaty*, and effectually to restore the peace in the North, would not that have been more for our interest, more necessary, more honourable and just, and more according to our Treaty; and would not the several 100,000 pounds these our Northern expeditions have cost the nation, have been thus better employed?

“*Query XIV.* If the preserving and securing our trade against the Swedes has been the only and real object of all our measures, as to the Northern affairs, how came we the year before the last to leave eight men-of-war in the Baltic and at Copenhagen, when we had no more trade there to protect, and how came Admiral Norris last summer, although he and the Dutch together made up the number of twenty-six men-of-war, and consequently were too strong for the Swedes, to attempt anything against our trade under their convoy; yet to lay above two whole months of the best season in the Sound, without convoying our and the Dutch merchantmen to the several ports they were bound for, whereby they were kept in the Baltic so late that their return could not but be very hazardous, as it even proved, both to them and our men-of-war themselves? Will not the world be apt to think that the hopes of forcing the King of Sweden to an inglorious and disadvantageous peace, by which the Duchies of Bremen and Verden ought to be added to the Hanover dominions, or that some other such view, foreign, if not contrary, to the true and old interest of Great Britain, had then a greater influence upon all these our proceedings than *the pretended care of our trade*?

“*Article XVIII.* For as much as it seems convenient for the preservation of the liberty of navigation and commerce in the Baltic Sea, that a firm and exact friendship should be kept between the Kings of Sweden and Denmark; and whereas the former Kings of Sweden and Denmark did oblige themselves mutually, not only by the public Articles of Peace made in the camp of Copenhagen, on the 27th of May, 1660, and by the ratifications of the agreement interchanged on both sides, sacredly and inviolably to observe all and every one of the clauses comprehended in the said agreement, but also declared together to ... Charles II., King of Great Britain ... a little before the treaty concluded between England and Sweden in the year 1665, that they would stand sincerely ... to all ... of the Articles of the said peace ... whereupon Charles II., with the approbation and

consent of both the forementioned Kings of Sweden and Denmark, took upon himself a little after the Treaty concluded between England and Sweden, 1st March, 1665, to wit 9th October, 1665, guarantee of the same agreements.... Whereas an instrument of peace between ... the Kings of Sweden and Denmark happened to be soon after these concluded at Lunden in Schonen, in 1679, which contains an express transaction, and repetition and confirmation of the Treaties concluded at Roskild, Copenhagen, and Westphalia; therefore ... the King of Great Britain binds himself by the force of this Treaty ... that if either of the Kings of Sweden and Denmark shall consent to the violation, either of all the agreements, or of one or more articles comprehended in them, and consequently if either of the Kings shall to the prejudice of the person, provinces, territories, islands, goods, dominions and rights of the other, which by the force of the agreements so often repeated, and made in the camp of Copenhagen, on the 27th of May, 1660, as also of those made in the ... peace at Lunden in Schonen in 1679, were attributed to every one that was interested and comprehended in the words of the peace, should either by himself or by others, presume, or secretly design or attempt, or by open molestations, or by any injury, or by any violence of arms, attempt anything; that then the ... King of Great Britain ... shall first of all, by his interposition, perform all the offices of a friend and princely ally, which may serve towards the keeping inviolable all the frequently mentioned agreements, and of every article comprehended in them, and consequently towards the preservation of peace between both kings; that afterwards if the King, who is the beginner of such prejudice, or any molestation or injury, contrary to all agreements, and contrary to any articles comprehended in them, shall refuse after being admonished ... then the King of Great Britain ... shall ... assist him that is injured as by the present agreements between the Kings of Great Britain and Sweden in such cases is determined and agreed.

“Query. Does not this article expressly tell us how to remedy the disturbances our trade in the Baltic might suffer, in case of a misunderstanding betwixt the Kings of Sweden and Denmark, by obliging both these Princes to keep all the Treaties of Peace that have been concluded between them from 1660-1670, and in case either of them should in an hostile manner act against the said Treaties, by assisting the other against the aggressor? How comes it then that we don’t make use of so just a remedy against an evil we are so great sufferers by? Can anybody, though

ever so partial, deny but the King of Denmark, though seemingly a sincere friend to the King of Sweden, from the peace of Travendahl till he went out of Saxony against the Muscovites, fell very unjustly upon him immediately after, taking ungenerously advantage of the fatal battle of Pultava? Is not then the King of Denmark the violator of all the above-mentioned Treaties, and consequently the true author of the disturbances our trade meets with in the Baltic? Why in God's name don't we, according to this article, assist Sweden against him, and why do we, on the contrary, declare openly against the injured King of Sweden, send hectoring and threatening memorials to him, upon the least advantage he has over his enemies, as we did last summer upon his entering Norway, and even order our fleets to act openly against him in conjunction with the Danes?

“*Article XIX.* There shall be ‘stricter confederacy and union between the above-mentioned Kings of Great Britain and Sweden, for the future, *for the defence and preservation of the Protestant, Evangelic, and reformed religion.*’

“*Query I.* How do we, according to this article, join with Sweden to *assert, protect, and preserve the Protestant religion?* Don't we suffer that nation, which has always been a bulwark to the said religion, most unmercifully to be torn to pieces?... *Don't we ourselves give a helping hand towards its destruction?* And why all this? Because our merchants have lost their ships to the value of sixty odd thousand pounds. *For this loss, and nothing else, was the pretended reason why, in the year 1715, we sent our fleet in the Baltic, at the expense of £200,000;* and as to what our merchants have suffered since, suppose we attribute it to our threatening memorials as well as open hostilities against the King of Sweden, must we not even then own that that Prince's resentment has been very moderate?

“*Query II.* How can other Princes, and especially our fellow Protestants, think us sincere in what we have made them believe as to our zeal in spending millions of lives and money for to secure the Protestant interest only in one single branch of it, *I mean the Protestant succession here,* when they see that that succession has hardly taken place, before we, only for sixty odd thousand pounds, (for let us always remember that this paltry sum was the first pretence for our quarrelling with Sweden) go about to undermine the very foundation of that interest in general, by helping, as we do, entirely to sacrifice Sweden, the old and sincere protector of the

Protestants, to its neighbours, of which some are professed Papists, some worse, and some, at least, but lukewarm Protestants?

“*Article XX.* Therefore, that a reciprocal faith of the Allies and their perseverance in this agreement may appear ... both the fore-mentioned kings mutually oblige themselves, and declare that ... they will not depart a tittle from the genuine and common sense of all and every article of this treaty under any pretences of friendship, profit, former treaty, agreement, and promise, or upon any colour whatsoever: but that they will most fully and readily, either by themselves, or ministers, or subjects, put in execution whatsoever they have promised in this treaty ... without any hesitation, exception, or excuse....

“*Query I.* Inasmuch as this article sets forth that, at the time of concluding of the treaty, we were under no engagement contrary to it, and that it were highly unjust should we afterwards, and while this treaty is in force, which is eighteen years after the day it was signed, have entered into any such engagements, how can we justify to the world our late proceedings against the King of Sweden, which naturally seem the consequences of a treaty either of our own making with the enemies of that Prince, *or of some Court or other that at present influences our measures?*

“*Query II.* The words in this article ... how in the name of honour, faith, and justice, do they agree with the *little and pitiful pretences* we now make use of, not only for not assisting Sweden, pursuant to this treaty, *but even for going about so heartily as we do to destroy it?*

“*Article XXI.* This defensive treaty shall last for eighteen years, before the end of which the confederate kings may ... again treat.

“*Ratification of the abovesaid treaty.* We, having seen and considered this treaty, have approved and confirmed the same in all and every particular article and clause as by the present. We do approve the same for us, our heirs, and successors; assuring and promising our princely word that we shall perform and observe sincerely and in good earnest all those things that are therein contained, for the better confirmation whereof we have ordered our great seal of England to be put to these presents, which were given at our palace of Kensington, 25th of February, in the year of our Lord 1700, and in the 11th year of our reign (Gulielmus Rex).

“*Query.* How can any of us that declares himself for the late happy revolution, and that is a true and grateful lover of King William’s for ever-glorious memory ... yet bear with the least patience, that the said treaty

should (that I may again use the words of the 20th article) be *departed from, under any pretence of profit, or upon any colour whatsoever*, especially so insignificant and trifling a one as that which has been made use of for two years together to employ our ships, our men, and our money, *to accomplish the ruin of Sweden*, that same Sweden whose defence and preservation this great and wise monarch of ours has so solemnly promised, and which he always looked upon to be of the utmost necessity for to secure the Protestant interest in Europe?”

CHAPTER V

Before entering upon an analysis of the pamphlet headed, "*Truth is but truth, as it is timed*," with which we shall conclude the *Introduction* to the *Diplomatic Revelations*, some preliminary remarks on the general history of Russian politics appear opportune.

The overwhelming influence of Russia has taken Europe at different epochs by surprise, startled the peoples of the West, and been submitted to as a fatality, or resisted only by convulsions. But alongside the fascination exercised by Russia, there runs an ever-reviving scepticism, dogging her like a shadow, growing with her growth, mingling shrill notes of irony with the cries of agonising peoples, and mocking her very grandeur as a histrionic attitude taken up to dazzle and to cheat. Other empires have met with similar doubts in their infancy; Russia has become a colossus without outliving them. She affords the only instance in history of an immense empire, the very existence of whose power, even after world-wide achievements, has never ceased to be treated like a matter of faith rather than like a matter of fact. From the outset of the eighteenth century to our days, no author, whether he intended to exalt or to check Russia, thought it possible to dispense with first proving her existence.

But whether we be spiritualists or materialists with respect to Russia — whether we consider her power as a palpable fact, or as the mere vision of the guilt-stricken consciences of the European peoples — the question remains the same: "How did this power, or this phantom of a power, contrive to assume such dimensions as to rouse on the one side the passionate assertion, and on the other the angry denial of its threatening the world with a rehearsal of Universal Monarchy?" At the beginning of the eighteenth century Russia was regarded as a mushroom creation extemporised by the genius of Peter the Great. Schloezer thought it a discovery to have found out that she possessed a past; and in modern times, writers, like Fallmerayer, unconsciously following in the track beaten by Russian historians, have deliberately asserted that the northern spectre which frightens the Europe of the nineteenth century already overshadowed the Europe of the ninth century. With them the policy of Russia begins with

the first Ruriks, and has, with some interruptions indeed, been systematically continued to the present hour.

Ancient maps of Russia are unfolded before us, displaying even larger European dimensions than she can boast of now: her perpetual movement of aggrandizement from the ninth to the eleventh century is anxiously pointed out; we are shown Oleg launching 88,000 men against Byzantium, fixing his shield as a trophy on the gate of that capital, and dictating an ignominious treaty to the Lower Empire; Igor making it tributary; Sviataslaff glorying, “the Greeks supply me with gold, costly stuffs, rice, fruits and wine; Hungary furnishes cattle and horses; from Russia I draw honey, wax, furs, and men”; Vladimir conquering the Crimea and Livonia, extorting a daughter from the Greek Emperor, as Napoleon did from the German Emperor, blending the military sway of a northern conqueror with the theocratic despotism of the Porphyro-geniti, and becoming at once the master of his subjects on earth, and their protector in heaven.

Yet, in spite of the plausible parallelism suggested by these reminiscences, the policy of the first Ruriks differs fundamentally from that of modern Russia. It was nothing more nor less than the policy of the German barbarians inundating Europe — the history of the modern nations beginning only after the deluge has passed away. The Gothic period of Russia in particular forms but a chapter of the Norman conquests. As the empire of Charlemagne precedes the foundation of modern France, Germany, and Italy, so the empire of the Ruriks precedes the foundation of Poland, Lithuania, the Baltic Settlements, Turkey, and Muscovy itself. The rapid movement of aggrandizement was not the result of deep-laid schemes, but the natural offspring of the primitive organization of Norman conquest — vassalship without fiefs, or fiefs consisting only in tributes — the necessity of fresh conquests being kept alive by the uninterrupted influx of new Varangian adventurers, panting for glory and plunder. The chiefs, becoming anxious for repose, were compelled by the Faithful Band to move on, and in Russian, as in French Normandy, there arrived the moment when the chiefs despatched on new predatory excursions their uncontrollable and insatiable companions-in-arms with the single view to get rid of them. Warfare and organization of conquest on the part of the first Ruriks differ in no point from those of the Normans in the rest of Europe. If Slavonian tribes were subjected not only by the sword, but also by mutual convention, this singularity is due to the exceptional position of those tribes, placed

between a northern and eastern invasion, and embracing the former as a protection from the latter. The same magic charm which attracted other northern barbarians to the Rome of the West attracted the Varangians to the Rome of the East. The very migration of the Russian capital — Rurik fixing it at Novgorod, Oleg removing it to Kiev, and Sviataslaff attempting to establish it in Bulgaria — proves beyond doubt that the invader was only feeling his way, and considered Russia as a mere halting-place from which to wander on in search of an empire in the South. If modern Russia covets the possession of Constantinople to establish her dominion over the world, the Ruriks were, on the contrary, forced by the resistance of Byzantium, under Zimiskes, definitively to establish their dominion in Russia.

It may be objected that victors and vanquished amalgamated more quickly in Russia than in any other conquest of the northern barbarians, that the chiefs soon commingled themselves with the Slavonians — as shown by their marriages and their names. But then, it should be recollected that the Faithful Band, which formed at once their guard and their privy council, remained exclusively composed of Varangians; that Vladimir, who marks the summit, and Yaroslav, who marks the commencing decline of Gothic Russia, were seated on her throne by the arms of the Varangians. If any Slavonian influence is to be acknowledged in this epoch, it is that of Novgorod, a Slavonian State, the traditions, policy, and tendencies of which were so antagonistic to those of modern Russia that the one could found her existence only on the ruins of the other. Under Yaroslav the supremacy of the Varangians is broken, but simultaneously with it disappears the conquering tendency of the first period, and the decline of Gothic Russia begins. The history of that decline, more still than that of the conquest and formation, proves the exclusively Gothic character of the Empire of the Ruriks.

The incongruous, unwieldy, and precocious Empire heaped together by the Ruriks, like the other empires of similar growth, is broken up into appanages, divided and subdivided among the descendants of the conquerors, dilacerated by feudal wars, rent to pieces by the intervention of foreign peoples. The paramount authority of the Grand Prince vanishes before the rival claims of seventy princes of the blood. The attempt of Andrew of Susdal at recomposing some large limbs of the empire by the removal of the capital from Kiev to Vladimir proves successful only in propagating the decomposition from the South to the centre. Andrew's third

successor resigns even the last shadow of supremacy, the title of Grand Prince, and the merely nominal homage still offered him. The appanages to the South and to the West become by turns Lithuanian, Polish, Hungarian, Livonian, Swedish. Kiev itself, the ancient capital, follows destinies of its own, after having dwindled down from a seat of the Grand Princedom to the territory of a city. Thus, the Russia of the Normans completely disappears from the stage, and the few weak reminiscences in which it still outlived itself, dissolve before the terrible apparition of Genghis Khan. The bloody mire of Mongolian slavery, not the rude glory of the Norman epoch, forms the cradle of Muscovy, and modern Russia is but a metamorphosis of Muscovy.

The Tartar yoke lasted from 1237 to 1462 — more than two centuries; a yoke not only crushing, but dishonouring and withering the very soul of the people that fell its prey. The Mongol Tartars established a rule of systematic terror, devastation and wholesale massacre forming its institutions. Their numbers being scanty in proportion to their enormous conquests, they wanted to magnify them by a halo of consternation, and to thin, by wholesale slaughter, the populations which might rise in their rear. In their creations of desert they were, besides, led by the same economical principle which has depopulated the Highlands of Scotland and the Campagna di Roma — the conversion of men into sheep, and of fertile lands and populous abodes into pasturage.

The Tartar yoke had already lasted a hundred years before Muscovy emerged from its obscurity. To entertain discord among the Russian princes, and secure their servile submission, the Mongols had restored the dignity of the Grand Princedom. The strife among the Russian princes for this dignity was, as a modern author has it, “an abject strife — the strife of slaves, whose chief weapon was calumny, and who were always ready to denounce each other to their cruel rulers; wrangling for a degraded throne, whence they could not move but with plundering, parricidal hands — hands filled with gold and stained with gore; which they dared not ascend without grovelling, nor retain but on their knees, prostrate and trembling beneath the scimitar of a Tartar, always ready to roll under his feet those servile crowns, and the heads by which they were worn.” It was in this infamous strife that the Moscow branch won at last the race. In 1328 the crown of the Grand Princedom, wrested from the branch of Tver by dint of denunciation and

assassination, was picked up at the feet of Usbeck Khan by Yury, the elder brother of Ivan Kalita. Ivan I. Kalita, and Ivan III., surnamed the Great, personate Muscovy rising by means of the Tartar yoke, and Muscovy getting an independent power by the disappearance of the Tartar rule. The whole policy of Muscovy, from its first entrance into the historical arena, is resumed in the history of these two individuals.

The policy of Ivan Kalita was simply this: to play the abject tool of the Khan, thus to borrow his power, and then to turn it round upon his princely rivals and his own subjects. To attain this end, he had to insinuate himself with the Tartars by dint of cynical adulation, by frequent journeys to the Golden Horde, by humble prayers for the hand of Mongol princesses, by a display of unbounded zeal for the Khan's interest, by the unscrupulous execution of his orders, by atrocious calumnies against his own kinsfolk, by blending in himself the characters of the Tartar's hangman, sycophant, and slave-in-chief. He perplexed the Khan by continuous revelations of secret plots. Whenever the branch of Tver betrayed a velleité of national independence, he hurried to the Horde to denounce it. Wherever he met with resistance, he introduced the Tartar to trample it down. But it was not sufficient to act a character; to make it acceptable, gold was required. Perpetual bribery of the Khan and his grandees was the only sure foundation upon which to raise his fabric of deception and usurpation. But how was the slave to get the money wherewith to bribe the master? He persuaded the Khan to instal him his tax-gatherer throughout all the Russian appanages. Once invested with this function, he extorted money under false pretences. The wealth accumulated by the dread held out of the Tartar name, he used to corrupt the Tartars themselves. By a bribe he induced the primate to transfer his episcopal seat from Vladimir to Moscow, thus making the latter the capital of the empire, because the religious capital, and coupling the power of the Church with that of his throne. By a bribe he allured the Boyards of the rival princes into treason against their chiefs, and attracted them to himself as their centre. By the joint influence of the Mahometan Tartar, the Greek Church, and the Boyards, he unites the princes holding appanages into a crusade against the most dangerous of them — the prince of Tver; and then having driven his recent allies by bold attempts at usurpation into resistance against himself, into a war for the public good, he draws not the sword but hurries to the Khan. By bribes and

delusion again, he seduces him into assassinating his kindred rivals under the most cruel torments. It was the traditional policy of the Tartar to check the Russian princes the one by the other, to feed their dissensions, to cause their forces to equiponderate, and to allow none to consolidate himself. Ivan Kalita converts the Khan into the tool by which he rids himself of his most dangerous competitors, and weighs down every obstacle to his own usurping march. He does not conquer the appanages, but surreptitiously turns the rights of the Tartar conquest to his exclusive profit. He secures the succession of his son through the same means by which he had raised the Grand Principedom of Muscovy, that strange compound of principedom and serfdom. During his whole reign he swerves not once from the line of policy he had traced to himself; clinging to it with a tenacious firmness, and executing it with methodical boldness. Thus he becomes the founder of the Muscovite power, and characteristically his people call him Kalita — that is, the purse, because it was the purse and not the sword with which he cut his way. The very period of his reign witnesses the sudden growth of the Lithuanian power which dismembers the Russian appanages from the West, while the Tartar squeezes them into one mass from the East. Ivan, while he dared not repulse the one disgrace, seemed anxious to exaggerate the other. He was not to be seduced from following up his ends by the allurements of glory, the pangs of conscience, or the lassitude of humiliation. His whole system may be expressed in a few words: the machiavelism of the usurping slave. His own weakness — his slavery — he turned into the mainspring of his strength.

The policy traced by Ivan I. Kalita is that of his successors; they had only to enlarge the circle of its application. They followed it up laboriously, gradually, inflexibly. From Ivan I. Kalita, we may, therefore, pass at once to Ivan III., surnamed the Great.

At the commencement of his reign (1462-1505) Ivan III. was still a tributary to the Tartars; his authority was still contested by the princes holding appanages; Novgorod, the head of the Russian republics, reigned over the north of Russia; Poland-Lithuania was striving for the conquest of Muscovy; lastly, the Livonian knights were not yet disarmed. At the end of his reign we behold Ivan III. seated on an independent throne, at his side the daughter of the last emperor of Byzantium, at his feet Kasan, and the remnant of the Golden Horde flocking to his court; Novgorod and the other Russian republics enslaved — Lithuania diminished, and its king a tool in

Ivan's hands — the Livonian knights vanquished. Astonished Europe, at the commencement of Ivan's reign, hardly aware of the existence of Muscovy, hemmed in between the Tartar and the Lithuanian, was dazzled by the sudden appearance of an immense empire on its eastern confines, and Sultan Bajazet himself, before whom Europe trembled, heard for the first time the haughty language of the Muscovite. How, then, did Ivan accomplish these high deeds? Was he a hero? The Russian historians themselves show him up a confessed coward.

Let us shortly survey his principal contests, in the sequence in which he undertook and concluded them — his contests with the Tartars, with Novgorod, with the princes holding appanages, and lastly with Lithuania-Poland.

Ivan rescued Muscovy from the Tartar yoke, not by one bold stroke, but by the patient labour of about twenty years. He did not break the yoke, but disengaged himself by stealth. Its overthrow, accordingly, has more the look of the work of nature than the deed of man. When the Tartar monster expired at last, Ivan appeared at its deathbed like a physician, who prognosticated and speculated on death rather than like a warrior who imparted it. The character of every people enlarges with its enfranchisement from a foreign yoke; that of Muscovy in the hands of Ivan seems to diminish. Compare only Spain in its struggles against the Arabs with Muscovy in its struggles against the Tartars.

At the period of Ivan's accession to the throne, the Golden Horde had long since been weakened, internally by fierce feuds, externally by the separation from them of the Nogay Tartars, the eruption of Timour Tamerlane, the rise of the Cossacks, and the hostility of the Crimean Tartars. Muscovy, on the contrary, by steadily pursuing the policy traced by Ivan Kalita, had grown to a mighty mass, crushed, but at the same time compactly united by the Tartar chain. The Khans, as if struck by a charm, had continued to remain instruments of Muscovite aggrandizement and concentration. By calculation they had added to the power of the Greek Church, which, in the hand of the Muscovite grand princes, proved the deadliest weapon against them.

In rising against the Horde, the Muscovite had not to invent but only to imitate the Tartars themselves. But Ivan did not rise. He humbly acknowledged himself a slave of the Golden Horde. By bribing a Tartar woman he seduced the Khan into commanding the withdrawal from

Muscovy of the Mongol residents. By similar and imperceptible and surreptitious steps he duped the Khan into successive concessions, all ruinous to his sway. He thus did not conquer, but filch strength. He does not drive, but manœuvre his enemy out of his strongholds. Still continuing to prostrate himself before the Khan's envoys, and to proclaim himself his tributary, he eludes the payment of the tribute under false pretences, employing all the stratagems of a fugitive slave who dare not front his owner, but only steal out of his reach. At last the Mongol awakes from his torpor, and the hour of battle sounds. Ivan, trembling at the mere semblance of an armed encounter, attempts to hide himself behind his own fear, and to disarm the fury of his enemy by withdrawing the object upon which to wreak his vengeance. He is only saved by the intervention of the Crimean Tartars, his allies. Against a second invasion of the Horde, he ostentatiously gathers together such disproportionate forces that the mere rumour of their number parries the attack. At the third invasion, from the midst of 200,000 men, he absconds a disgraced deserter. Reluctantly dragged back, he attempts to haggle for conditions of slavery, and at last, pouring into his army his own servile fear, he involves it in a general and disorderly flight. Muscovy was then anxiously awaiting its irretrievable doom, when it suddenly hears that by an attack on their capital made by the Crimean Khan, the Golden Horde has been forced to withdraw, and has, on its retreat, been destroyed by the Cossacks and Nogay Tartars. Thus defeat was turned into success, and Ivan had overthrown the Golden Horde, not by fighting it himself, but by challenging it through a feigned desire of combat into offensive movements, which exhausted its remnants of vitality and exposed it to the fatal blows of the tribes of its own race whom he had managed to turn into his allies. He caught one Tartar with another Tartar. As the immense danger he had himself summoned proved unable to betray him into one single trait of manhood, so his miraculous triumph did not infatuate him even for one moment. With cautious circumspection he dared not incorporate Kasan with Muscovy, but made it over to sovereigns belonging to the family of Menghi-Ghirei, his Crimean ally, to hold it, as it were, in trust for Muscovy. With the spoils of the vanquished Tartar, he enchained the victorious Tartar. But if too prudent to assume, with the eye-witnesses of his disgrace, the airs of a conqueror, this impostor did fully understand how the downfall of the Tartar empire must dazzle at a distance — with what halo of glory it would encircle him, and how it would facilitate a

magnificent entry among the European Powers. Accordingly he assumed abroad the theatrical attitude of the conqueror, and, indeed, succeeded in hiding under a mask of proud susceptibility and irritable haughtiness the obtrusiveness of the Mongol serf, who still remembered kissing the stirrup of the Khan's meanest envoy. He aped in more subdued tone the voice of his old masters, which terrified his soul. Some standing phrases of modern Russian diplomacy, such as the magnanimity, the wounded dignity of the master, are borrowed from the diplomatic instructions of Ivan III.

After the surrender of Kasan, he set out on a long-planned expedition against Novgorod, the head of the Russian republics. If the overthrow of the Tartar yoke was, in his eyes, the first condition of Muscovite greatness, the overthrow of Russian freedom was the second. As the republic of Viatka had declared itself neutral between Muscovy and the Horde, and the republic of Tskof, with its twelve cities, had shown symptoms of disaffection, Ivan flattered the latter and affected to forget the former, meanwhile concentrating all his forces against Novgorod the Great, with the doom of which he knew the fate of the rest of the Russian republics to be sealed. By the prospect of sharing in this rich booty, he drew after him the princes holding appanages, while he inveigled the boyards by working upon their blind hatred of Novgorodian democracy. Thus he contrived to march three armies upon Novgorod and to overwhelm it by disproportionate force. But then, in order not to keep his word to the princes, not to forfeit his immutable "*Vos non vobis*," at the same time apprehensive, lest Novgorod should not yet have become digestible from the want of preparatory treatment, he thought fit to exhibit a sudden moderation; to content himself with a ransom and the acknowledgment of his suzerainty; but into the act of submission of the republic he smuggled some ambiguous words which made him its supreme judge and legislator. Then he fomented the dissensions between the patricians and plebeians raging as well in Novgorod as at Florence. Of some complaints of the plebeians he took occasion to introduce himself again into the city, to have its nobles, whom he knew to be hostile to himself, sent to Moscow loaded with chains, and to break the ancient law of the republic that "none of its citizens should ever be tried or punished out of the limits of its own territory." From that moment he became supreme arbiter. "Never," say the annalists, "never since Rurik had such an event happened; never had the grand princes of Kiev and Vladimir seen the Novgorodians come and submit to them as their judges.

Ivan alone could reduce Novgorod to that degree of humiliation.” Seven years were employed by Ivan to corrupt the republic by the exercise of his judicial authority. Then, when he found its strength worn out, he thought the moment ripe for declaring himself. To doff his own mask of moderation, he wanted, on the part of Novgorod, a breach of the peace. As he had simulated calm endurance, so he simulated now a sudden burst of passion. Having bribed an envoy of the republic to address him during a public audience with the name of sovereign, he claimed, at once, all the rights of a despot — the self-annihilation of the republic.

CHAPTER VI

One feature characteristic of the Slavonic race must strike every observer. Almost everywhere it confined itself to an inland country, leaving the sea-borders to non-Slavonic tribes. Finno-Tartaric tribes held the shores of the Black Sea, Lithuanians and Fins those of the Baltic and White Sea. Wherever they touched the sea-board, as in the Adriatic and part of the Baltic, the Slavonians had soon to submit to foreign rule. The Russian people shared this common fate of the Slavonian race. Their home, at the time they first appear in history, was the country about the sources and upper course of the Volga and its tributaries, the Dnieper, Don, and Northern Dwina. Nowhere did their territory touch the sea except at the extremity of the Gulf of Finland. Nor had they before Peter the Great proved able to conquer any maritime outlet beside that of the White Sea, which, during three-fourths of the year, is itself enchained and immovable. The spot where Petersburg now stands had been for a thousand years past contested ground between Fins, Swedes, and Russians. All the remaining extent of coast from Polangen, near Memel, to Torrea, the whole coast of the Black Sea, from Akerman to Redut Kaleh, has been conquered later on. And, as if to witness the anti-maritime peculiarity of the Slavonic race, of all this line of coast, no portion of the Baltic coast has really adopted Russian nationality. Nor has the Circassian and Mingrelian east coast of the Black Sea. It is only the coast of the White Sea, as far as it was worth cultivating, some portion of the northern coast of the Black Sea, and part of the coast of the Sea of Azof, that have really been peopled with Russian inhabitants, who, however, despite the new circumstances in which they are placed, still refrain from taking to the sea, and obstinately stick to the land-lopers' traditions of their ancestors.

From the very outset, Peter the Great broke through all the traditions of the Slavonic race. "It is water that Russia wants." These words he addressed as a rebuke to Prince Cantemir are inscribed on the title-page of his life. The conquest of the Sea of Azof was aimed at in his first war with Turkey, the conquest of the Baltic in his war against Sweden, the conquest of the Black Sea in his second war against the Porte, and the conquest of the Caspian Sea in his fraudulent intervention in Persia. For a system of local

encroachment, land was sufficient; for a system of universal aggression, water had become indispensable. It was but by the conversion of Muscovy from a country wholly of land into a sea-bordering empire, that the traditional limits of the Muscovite policy could be superseded and merged into that bold synthesis which, blending the encroaching method of the Mongol slave with the world-conquering tendencies of the Mongol master, forms the life-spring of modern Russian diplomacy.

It has been said that no great nation has ever existed, or been able to exist, in such an inland position as that of the original empire of Peter the Great; that none has ever submitted thus to see its coasts and the mouths of its rivers torn away from it; that Russia could no more leave the mouth of the Neva, the natural outlet for the produce of Northern Russia, in the hands of the Swedes, than the mouths of the Don, Dnieper, and Bug, and the Straits of Kertch, in the hands of nomadic and plundering Tartars; that the Baltic provinces, from their very geographical configuration, are naturally a corollary to whichever nation holds the country behind them; that, in one word, Peter, in this quarter, at least, but took hold of what was absolutely necessary for the natural development of his country. From this point of view, Peter the Great intended, by his war against Sweden, only rearing a Russian Liverpool, and endowing it with its indispensable strip of coast.

But then, one great fact is slighted over, the *tour de force* by which he transferred the capital of the Empire from the inland centre to the maritime extremity, the characteristic boldness with which he erected the new capital on the first strip of Baltic coast he conquered, almost within gunshot of the frontier, thus deliberately giving his dominions an *eccentric centre*. To transfer the throne of the Czars from Moscow to Petersburg was to place it in a position where it could not be safe, even from insult, until the whole coast from Libau to Tornea was subdued — a work not completed till 1809, by the conquest of Finland. “St. Petersburg is the window from which Russia can overlook Europe,” said Algarotti. It was from the first a defiance to the Europeans, an incentive to further conquest to the Russians. The fortifications in our own days of Russian Poland are only a further step in the execution of the same idea. Modlin, Warsaw, Ivangorod, are more than citadels to keep a rebellious country in check. They are the same menace to the west which Petersburg, in its immediate bearing, was a hundred years ago to the north. They are to transform Russia into Panslavonia, as the Baltic provinces were to transform Muscovy into Russia.

Petersburg, the *eccentric centre* of the empire, pointed at once to a periphery still to be drawn.

It is, then, not the mere conquest of the Baltic provinces which separates the policy of Peter the Great from that of his ancestors, but it is the transfer of the capital which reveals the true meaning of his Baltic conquests. Petersburg was not like Muscovy, the centre of a race, but the seat of a government; not the slow work of a people, but the instantaneous creation of a man; not the medium from which the peculiarities of an inland people radiate, but the maritime extremity where they are lost; not the traditional nucleus of a national development, but the deliberately chosen abode of a cosmopolitan intrigue. By the transfer of the capital, Peter cut off the natural ligaments which bound up the encroaching system of the old Muscovite Czars with the natural abilities and aspirations of the great Russian race. By planting his capital on the margin of a sea, he put to open defiance the anti-maritime instincts of that race, and degraded it to a mere weight in his political mechanism. Since the 16th century Muscovy had made no important acquisitions but on the side of Siberia, and to the 16th century the dubious conquests made towards the west and the south were only brought about by direct agency on the east. By the transfer of the capital, Peter proclaimed that he, on the contrary, intended working on the east and the immediately neighbouring countries through the agency of the west. If the agency through the east was narrowly circumscribed by the stationary character and the limited relations of Asiatic peoples, the agency through the west became at once illimited and universal from the movable character and the all-sided relations of Western Europe. The transfer of the capital denoted this intended change of agency, which the conquest of the Baltic provinces afforded the means of achieving, by securing at once to Russia the supremacy among the neighbouring Northern States; by putting it into immediate and constant contact with all points of Europe; by laying the basis of a material bond with the maritime Powers, which by this conquest became dependent on Russia for their naval stores; a dependence not existing as long as Muscovy, the country that produced the great bulk of the naval stores, had got no outlets of its own; while Sweden, the Power that held these outlets, had not got the country lying behind them.

If the Muscovite Czars, who worked their encroachments by the agency principally of the Tartar Khans, were obliged to *tartarize* Muscovy, Peter the Great, who resolved upon working through the agency of the west, was

obliged to *civilize* Russia. In grasping upon the Baltic provinces, he seized at once the tools necessary for this process. They afforded him not only the diplomatists and the generals, the brains with which to execute his system of political and military action on the west, they yielded him, at the same time, a crop of bureaucrats, schoolmasters, and drill-sergeants, who were to drill Russians into that varnish of civilization that adapts them to the technical appliances of the Western peoples, without imbuing them with their ideas.

Neither the Sea of Azof, nor the Black Sea, nor the Caspian Sea, could open to Peter this direct passage to Europe. Besides, during his lifetime still Taganrog, Azof, the Black Sea, with its new-formed Russian fleets, ports, and dockyards, were again abandoned or given up to the Turk. The Persian conquest, too, proved a premature enterprise. Of the four wars which fill the military life of Peter the Great, his first war, that against Turkey, the fruits of which were lost in a second Turkish war, continued in one respect the traditionary struggle with the Tartars. In another respect, it was but the prelude to the war against Sweden, of which the second Turkish war forms an episode and the Persian war an epilogue. Thus the war against Sweden, lasting during twenty-one years, almost absorbs the military life of Peter the Great. Whether we consider its purpose, its results, or its endurance, we may justly call it *the* war of Peter the Great. His whole creation hinges upon the conquest of the Baltic coast.

Now, suppose we were altogether ignorant of the details of his operations, military and diplomatic. The mere fact that the conversion of Muscovy into Russia was brought about by its transformation from a half-Asiatic inland country into the paramount maritime Power of the Baltic, would it not enforce upon us the conclusion that England, the greatest maritime Power of that epoch — a maritime Power lying, too, at the very gates of the Baltic, where, since the middle of the 17th century, she had maintained the attitude of supreme arbiter — that England must have had her hand in this great change, that she must have proved the main prop or the main impediment of the plans of Peter the Great, that during the long protracted and deadly struggle between Sweden and Russia she must have turned the balance, that if we do not find her straining every nerve in order to save the Swede we may be sure of her having employed all the means at her disposal for furthering the Muscovite? And yet, in what is commonly

called history, England does hardly appear on the plan of this grand drama, and is represented as a spectator rather than as an actor. Real history will show that the Khans of the Golden Horde were no more instrumental in realizing the plans of Ivan III. and his predecessors than the rulers of England were in realizing the plans of Peter I. and his successors.

The pamphlets which we have reprinted, written as they were by English contemporaries of Peter the Great, are far from concurring in the common delusions of later historians. They emphatically denounce England as the mightiest tool of Russia. The same position is taken up by the pamphlet of which we shall now give a short analysis, and with which we shall conclude the introduction to the diplomatic revelations. It is entitled, "*Truth is but Truth as it is timed; or, our Ministry's present measures against the Muscovite vindicated*, etc., etc. Humbly dedicated to the House of C., London, 1719."

The former pamphlets we have reprinted, were written at, or shortly after, the time when, to use the words of a modern admirer of Russia, "Peter traversed the Baltic Sea as master at the head of the combined squadrons of all the northern Powers, England included, which gloried in sailing under his orders." In 1719, however, when *Truth is but Truth* was published, the face of affairs seemed altogether changed. Charles XII. was dead, and the English Government now pretended to side with Sweden, and to wage war against Russia. There are other circumstances connected with this anonymous pamphlet which claim particular notice. It purports to be an extract from a relation, which, on his return from Muscovy, in August, 1715, its author, by order of George I., drew up and handed over to Viscount Townshend, then Secretary of State.

"It happens," says he, "to be an advantage that at present I may own to have been the first so happy to foresee, or honest to forewarn our Court here, of the absolute necessity of our then breaking with the Czar, and shutting him out again of the Baltic." "My relation discovered his aim as to other States, and even to the German Empire, to which, although an inland Power, he had offered to annex Livonia as an Electorate, so that he could but be admitted as an elector. It drew attention to the Czar's then contemplated assumption of the title of Autocrat. Being head of the Greek Church he would be owned by the other potentates as head of the Greek Empire. I am not to say how reluctant we would be to acknowledge that

title, since we have already made an ambassador treat him with the title of Imperial Majesty, which the Swede has never yet condescended to.”

For some time attached to the British Embassy in Muscovy, our author, as he states, was later on “*dismissed the service, because the Czar desired it,*” having made sure that

“I had given our Court such light into his affairs as is contained in this paper; for which I beg leave to appeal to the King, and to vouch the Viscount Townshend, who heard his Majesty give that vindication.” “And yet, notwithstanding all this, I have been for these five years past kept soliciting for a very long arrear still due, and whereof I contracted the greatest part in executing a commission for her late Majesty.”

The anti-Muscovite attitude, suddenly assumed by the Stanhope Cabinet, our author looks to in rather a sceptic mood.

“I do not pretend to foreclose, by this paper, the Ministry of that applause due to them from the public, when they shall satisfy us as to what the motives were which made them, till but yesterday, straiten the Swede in everything, although then our ally as much as now; or strengthen, by all the ways they could, the Czar, although under no tie, but barely that of amity with Great Britain.... At the minute I write this I learn that the gentleman who brought the Muscovites, not yet three years ago, as a royal navy, not under our protection, on their first appearance in the Baltic, is again authorized by the persons now in power, to give the Czar a second meeting in these seas. For what reason or to what good end?”

The gentleman hinted at is Admiral Norris, whose Baltic campaign against Peter I. seems, indeed, to be the original pattern upon which the recent naval campaigns of Admirals Napier and Dundas were cut out.

The restoration to Sweden of the Baltic provinces is required by the commercial as well as the political interest of Great Britain. Such is the pith of our author’s argument:

“Trade is become the very life of our State; and what food is to life, naval stores are to a fleet. The whole trade we drive with all the other nations of the earth, at best, is but lucrative; this, of the north, is indispensably needful, and may not be improperly termed the *sacra embole* of Great Britain, as being its chiefest foreign vent, for the support of all our trade, and our safety at home. As woollen manufactures and minerals are the staple commodities of Great Britain, so are likewise naval stores those of Muscovy, as also of all those very provinces in the Baltic which the Czar

has so lately wrested from the crown of Sweden. Since those provinces have been in the Czar's possession, Pernan is entirely waste. At Revel we have not one British merchant left, and all the trade which was formerly at Narwa is now brought to Petersburg.... The Swede could never possibly engross the trade of our subjects, because those seaports in his hands were but so many thoroughfares from whence these commodities were uttered, the places of their produce or manufacture lying behind those ports, in the dominions of the Czar. But, if left to the Czar, these Baltic ports are no more thoroughfares, but peculiar magazines from the inland countries of the Czar's own dominions. Having already Archangel in the White Sea, to leave him but any seaport in the Baltic were to put no less in his hands than the *two keys of the general magazines of all the naval stores of Europe*; it being known that Danes, Swedes, Poles, and Prussians have but single and distinct branches of those commodities in their several dominions. If the Czar should thus engross 'the supply of what we cannot do without,' where then is our fleet? Or, indeed, where is the security for all our trade to any part of the earth besides?"

If, then, the interest of British commerce requires to exclude the Czar from the Baltic, the interest of our State ought to be no less a spur to quicken us to that attempt. By the interest of our State I would be understood to mean neither the party measures of a Ministry, nor any foreign motives of a Court, but precisely what is, and ever must be, the immediate concern, either for the safety, ease, dignity, or emolument of the Crown, as well as the common weal of Great Britain. With respect to the Baltic, it has "from the earliest period of our naval power" always been considered a fundamental interest of our State: first, to prevent the rise there of any new maritime Power; and, secondly, to maintain the balance of power between Denmark and Sweden.

"One instance of the wisdom and foresight of our *then truly British statesmen* is the peace at Stalboa, in the year 1617. James the First was the mediator of that treaty, by which the Muscovite was obliged to give up all the provinces which he then was possessed of in the Baltic, and to be barely an inland Power on this side of Europe."

The same policy of preventing a new maritime Power from starting in the Baltic was acted upon by Sweden and Denmark.

“Who knows not that the Emperor’s attempt to get a seaport in Pomerania weighed no less with the great Gustavus than any other motive for carrying his arms even into the bowels of the house of Austria? What befel, at the times of Charles Gustavus, the crown of Poland itself, who, besides it being in those days by far the mightiest of any of the northern Powers, had then a long stretch of coast on, and some ports in, the Baltic? The Danes, though then in alliance with Poland, would never allow them, even for their assistance against the Swedes, to have a fleet in the Baltic, but destroyed the Polish ships wherever they could meet them.”

As to the maintenance of the balance of power between the established maritime States of the Baltic, the tradition of British policy is no less clear. “When the Swedish power gave us some uneasiness there by threatening to crush Denmark,” the honour of our country was kept up by retrieving the then inequality of the balance of power.

The Commonwealth of England sent in a squadron to the Baltic which brought on the treaty of Roskild (1658), afterwards confirmed at Copenhagen (1660). The fire of straw kindled by the Danes in the times of King William III. was as speedily quenched by George Rock in the treaty of Copenhagen.

Such was the hereditary British policy.

“It never entered into the mind of the politicians of those times in order to bring the scale again to rights, to find out the happy *expedient of raising a third naval Power* for framing a juster balance in the Baltic.... Who has taken this counsel against Tyre, the crowning city, whose merchants are princes, whose traffickers are the honourables of the earth? *Ego autem neminem nomino, quare irasci mihi nemo poterit, nisi qui ante de se noluerit confiteri.* Posterity will be under some difficulty to believe that this could be the *work of any of the persons now in power ... that we have opened; St. Petersburg to the Czar solely at our own expense, and without any risk to him....*”

The safest line of policy would be to return to the treaty of Itolbowa, and to suffer the Muscovite no longer “to nestle in the Baltic.” Yet, it may be said, that in “the present state of affairs” it would be “difficult to retrieve the advantage we have lost by not curbing, when it was more easy, the growth of the Muscovite power.” A middle course may be thought more convenient.

“If we should find it consistent with the welfare of our State that the Muscovite have an inlet into the Baltic, as having, of all the princes of Europe, a country that can be made most beneficial to its prince, by uttering its produce to foreign markets. In this case, it were but reasonable to expect, on the other hand, that in return for our complying so far with his interest, for the improvement of his country, his Czarish Majesty, on his part, should demand nothing that may tend to the disturbance of another; and, therefore, contenting himself with ships of trade, should demand none of war.”

“We should thus preclude his hopes of being ever more than an inland Power,” but “obviate every objection of using the Czar worse than any Sovereign Prince may expect. I shall not for this give an instance of a Republic of Genoa, or another in the Baltic itself, of the Duke of Courland; but will assign Poland and Prussia, who, though both now crowned heads, have ever contented themselves with the freedom of an open traffic, without insisting on a fleet. Or the treaty of Falczin, between the Turk and Muscovite, by which Peter was forced not only to restore Asoph, and to part with all his men-of-war in those parts, but also to content himself with the bare freedom of traffic in the Black Sea. Even an inlet in the Baltic for trade is much beyond what he could morally have promised himself not yet so long ago on the issue of his war with Sweden.”

If the Czar refuse to agree to such “a healing temperament,” we shall have “nothing to regret but the time we lost to exert all the means that Heaven has made us master of, to reduce him to a peace advantageous to Great Britain.” War would become inevitable. In that case

“it ought no less to animate our Ministry to pursue their present measures, than fire with indignation the breast of every honest Briton that a Czar of Muscovy, who owes his naval skill to our instructions, and his grandeur to our forbearance, should so soon deny to Great Britain the terms which so few years ago he was fain to take up with from the Sublime Porte.”

“’Tis every way our interest to have the Swede restored to those provinces which the Muscovite has wrested from that crown in the Baltic. *Great Britain can no longer hold the balance in that sea,*” since she “*has raised the Muscovite to be a maritime Power there....* Had we performed the articles of our alliance made by King William with the crown of Sweden, that gallant nation would ever have been a bar strong enough against the

Czar coming into the Baltic.... Time must confirm us, that the Muscovite's *expulsion from the Baltic* is *now* the principal end of our Ministry."

REVOLUTION AND COUNTER-REVOLUTION

OR, GERMANY IN 1848

NOTE BY THE EDITOR

The following articles are now, after forty-five years, for the first time collected and printed in book form. They are an invaluable pendant to Marx's work on the *coup d'état* of Napoleon III. ("Der Achtzehnte Brumaire des Louis Bonaparte.") Both works belong to the same period, and both are what Engels calls "excellent specimens of that marvellous gift ... of Marx ... of apprehending clearly the character, the significance, and the necessary consequences of great historical events at a time when these events are actually in course of taking place, or are only just completed."

These articles were written in 1851-1852, when Marx had been about eighteen months in England. He was living with his wife, three young children, and their life-long friend, Helene Demuth, in two rooms in Dean Street, Soho, almost opposite the Royalty Theatre. For nearly ten years they had been driven from pillar to post. When, in 1843, the Prussian Government suppressed the *Rhenish Gazette* which Marx had edited, he went with his newly-married wife, Jenny von Westphalen, to Paris. Not long after, his expulsion was demanded by the Prussian Government — it is said that Alexander von Humboldt acted as the agent of Prussia on this occasion — and M. Guizot was, of course, too polite to refuse the request. Marx was expelled, and betook himself to Brussels. Again the Prussian Government requested his expulsion, and where the French Government had complied it was not likely the Belgian would refuse. Marx received marching orders.

But at this same time the French Government that had expelled Marx had gone the way of French Governments, and the new Provisional Government through Ferdinand Flocon invited the "brave et loyal Marx" to return to the country whence "tyranny had banished him, and where he, like all fighting in the sacred cause, the cause of the fraternity of all peoples," would be welcome. The invitation was accepted, and for some months he lived in Paris. Then he returned to Germany in order to start the *New Rhenish Gazette* in Cologne. And the *Rhenish Gazette* writers had very lively times. Marx was twice prosecuted, but as the juries would not convict, the Prussian Government took the nearer way and suppressed the paper.

Again Marx and his family returned to the country whose “doors” had only a few short months before been “thrown open” to him. The sky had changed — and the Government. “We remained in Paris,” my mother says in some biographical notes I have found, “a month. Here also there was to be no resting-place for us. One fine morning the familiar figure of the sergeant of police appeared with the announcement that Karl ‘et sa dame’ must leave Paris within twenty-four hours. We were graciously told we might be interned at Vannes in the Morbihan. Of course we could not accept such an exile as that, and I again gathered together my small belongings to seek a safe haven in London. Karl had hastened thither before us.” The “us” were my mother, Helene Demuth, and the three little children, Jenny (Madame Longuet), Laura (Madame Lafargue), and Edgar, who died at the age of eight.

The haven was safe indeed. But it was storm-tossed. Hundreds of refugees — all more or less destitute — were now in London. There followed years of horrible poverty, of bitter suffering — such suffering as can only be known to the penniless stranger in a strange land. The misery would have been unendurable but for the faith that was in these men and women, and but for their invincible “Humor.” I use the German word because I know no English one that quite expresses the same thing — such a combination of humor and good-humor, of light-hearted courage, and high spirits.

That readers of these articles may have some idea of the conditions under which Marx was working, under which he wrote them and the “Achtzehnte Brumaire,” and was preparing his first great economical work, “Zur Kritik der Politischen Oeconomie” (published in 1859), I again quote from my mother’s notes. Soon after the arrival of the family a second son was born. He died when about two years old. Then a fifth child, a little girl, was born. When about a year old, she too fell sick and died. “Three days,” writes my mother, “the poor child wrestled with death. She suffered so.... Her little dead body lay in the small back room; we all of us” (i.e., my parents, Helene Demuth, and the three elder children) “went into the front room, and when night came we made us beds on the floor, the three living children lying by us. And we wept for the little angel resting near us, cold and dead. The death of the dear child came in the time of our bitterest poverty. Our German friends could not help us; Engels, after vainly trying to get literary work in London, had been obliged to go, under very

disadvantageous conditions, into his father's firm, as a clerk, in Manchester; Ernest Jones, who often came to see us at this time, and had promised help, could do nothing.... In the anguish of my heart I went to a French refugee who lived near, and who had sometimes visited us. I told him our sore need. At once with the friendliest kindness he gave me £2. With that we paid for the little coffin in which the poor child now sleeps peacefully. I had no cradle for her when she was born, and even the last small resting-place was long denied her." ... "It was a terrible time," Liebknecht writes to me (the Editor), "but it was grand nevertheless."

In that "front room" in Dean Street, the children playing about him, Marx worked. I have heard tell how the children would pile up chairs behind him to represent a coach, to which he was harnessed as horse, and would "whip him up" even as he sat at his desk writing.

Marx had been recommended to Mr. C. A. Dana, the managing director of the *New York Tribune*, by Ferdinand Freiligrath, and the first contributions sent by him to America are the series of letters on Germany here reprinted. They seem to have created such a sensation that before the series had been completed Marx was engaged as regular London correspondent. On the 12th of March, 1852, Mr. Dana wrote: "It may perhaps give you pleasure to know that they" (i.e., the "Germany" letters) "are read with satisfaction by a considerable number of persons, and are widely reproduced." From this time on, with short intervals, Marx not only sent letters regularly to the New York paper; he wrote a large number of leading articles for it. "Mr. Marx," says an editorial note in 1853, "has indeed opinions of his own, with some of which we are far from agreeing; but those who do not read his letters neglect one of the most instructive sources of information on the great questions of European politics."

Not the least remarkable among these contributions were those dealing with Lord Palmerston and the Russian Government. "Urquhart's writings on Russia," says Marx, "had interested but not convinced me. In order to arrive at a definite opinion, I made a minute analysis of Hansard's Parliamentary Debates, and of the Diplomatic Blue Books from 1807 to 1850. The first fruits of these studies was a series of articles in the *New York Tribune*, in which I proved Palmerston's relations with the Russian Government.... Shortly after, these studies were reprinted in the Chartist organ edited by Ernest Jones, *The People's Paper*.... Meantime the Glasgow *Sentinel* had reproduced one of these articles, and part of it was issued in pamphlet form

by Mr. Tucker, London.” And the Sheffield Foreign Affairs Committee thanked Marx for the “great public service rendered by the admirable *exposé*” in his “Kars papers,” published both in the *New York Tribune* and the *People’s Paper*. A large number of articles on the subject were also printed in the *Free Press* by Marx’s old friend, C. D. Collett. I hope to republish these and other articles.

As to the *New York Tribune*, it was at this time an admirably edited paper, with an immense staff of distinguished contributors, both American and European. It was a passionate anti-slavery organ, and also recognized that there “was need for a true organization of society,” and that “our evils” were “social, not political.” The paper, and especially Marx’s articles, were frequently referred to in the House of Commons, notably by John Bright.

It may also interest readers to know what Marx was paid for his articles — many of them considerably longer even than those here collected. He received £1 for each contribution — not exactly brilliant remuneration.

It will be noted that the twentieth chapter, promised in the nineteenth, does not appear. It may have been written, but was certainly not printed. It was probably crowded out. “I do not know,” wrote Mr. Dana, “how long you intend to make the series, and under ordinary circumstances I should desire to have it prolonged as much as possible. But we have a presidential election at hand, which will occupy our columns to a great extent.... Let me suggest to you if possible to condense your survey ... into say half a dozen more articles” (eleven had then been received by Mr. Dana). “Do not, however, close it without an exposition of the forces now remaining at work there (Germany) and active in the preparation of the future.” This “exposition” will be found in the article which I have added to the “Germany” series, on the “Cologne Communist Trial.” That trial really gives a complete picture of the conditions of Germany under the triumphant Counter-Revolution.

Marx himself nowhere says the series of letters is incomplete, although he occasionally refers to them. Thus in the letter on the Cologne trial he speaks of the articles, and in 1853 writes: “Those of your readers who, having read my letters on the German Revolution and Counter-Revolution written for the *Tribune* some two years ago, desire to have an immediate intuition of it, will do well to inspect the picture by Mr. Hasenclever now being exhibited in ... New York ... representing the presentation of a

workingmen's petition to the magistrates of Düsseldorf in 1848. What the writer could only analyze, the eminent painter has reproduced in its dramatic vitality."

Finally, I would remind English readers that these articles were written when Marx had only been some eighteen months in England, and that he never had any opportunity of reading the proofs. Nevertheless, it has not seemed to me that anything needed correction. I have therefore only removed a few obvious printer's errors.

The date at the head of each chapter refers to the issue of the *Tribune* in which the article appeared, that at the end to the time of writing. I am alone responsible for the headings of the letters as published in this volume.

Sydenham, April, 1896.

I. GERMANY AT THE OUTBREAK OF THE REVOLUTION.

October 25, 1851.

The first act of the revolutionary drama on the continent of Europe has closed. The “powers that were” before the hurricane of 1848 are again the “powers that be,” and the more or less popular rulers of a day, provisional governors, triumvirs, dictators, with their tail of representatives, civil commissioners, military commissioners, prefects, judges, generals, officers, and soldiers, are thrown upon foreign shores, and “transported beyond the seas” to England or America, there to form new governments *in partibus infidelium*, European committees, central committees, national committees, and to announce their advent with proclamations quite as solemn as those of any less imaginary potentates.

A more signal defeat than that undergone by the continental revolutionary party — or rather parties — upon all points of the line of battle, cannot be imagined. But what of that? Has not the struggle of the British middle classes for their social and political supremacy embraced forty-eight, that of the French middle classes forty years of unexampled struggles? And was their triumph ever nearer than at the very moment when restored monarchy thought itself more firmly settled than ever? The times of that superstition which attributed revolutions to the ill-will of a few agitators have long passed away. Everyone knows nowadays that wherever there is a revolutionary convulsion, there must be some social want in the background, which is prevented, by outworn institutions, from satisfying itself. The want may not yet be felt as strongly, as generally, as might ensure immediate success; but every attempt at forcible repression will only bring it forth stronger and stronger, until it bursts its fetters. If, then, we have been beaten, we have nothing else to do but to begin again from the beginning. And, fortunately, the probably very short interval of rest which is allowed us between the close of the first and the beginning of the second act of the movement, gives us time for a very necessary piece of work: the study of the causes that necessitated both the late outbreak and its defeat; causes that are not to be sought for in the accidental efforts, talents, faults, errors, or treacheries of some of the leaders, but in the general social state and

conditions of existence of each of the convulsed nations. That the sudden movements of February and March, 1848, were not the work of single individuals, but spontaneous, irresistible manifestations of national wants and necessities, more or less clearly understood, but very distinctly felt by numerous classes in every country, is a fact recognized everywhere; but when you inquire into the causes of the counter-revolutionary successes, there you are met on every hand with the ready reply that it was Mr. This or Citizen That who “betrayed” the people. Which reply may be very true or not, according to circumstances, but under no circumstances does it explain anything — not even show how it came to pass that the “people” allowed themselves to be thus betrayed. And what a poor chance stands a political party whose entire stock-in-trade consists in a knowledge of the solitary fact that Citizen So-and-so is not to be trusted.

The inquiry into, and the exposition of, the causes, both of the revolutionary convulsion and its suppression, are, besides, of paramount importance from a historical point of view. All these petty, personal quarrels and recriminations — all these contradictory assertions that it was Marrast, or Ledru Rollin, or Louis Blanc, or any other member of the Provisional Government, or the whole of them, that steered the Revolution amidst the rocks upon which it foundered — of what interest can they be, what light can they afford, to the American or Englishman who observed all these various movements from a distance too great to allow of his distinguishing any of the details of operations? No man in his senses will ever believe that eleven men, mostly of very indifferent capacity either for good or evil, were able in three months to ruin a nation of thirty-six millions, unless those thirty-six millions saw as little of their way before them as the eleven did. But how it came to pass that thirty-six millions were at once called upon to decide for themselves which way to go, although partly groping in dim twilight, and how then they got lost and their old leaders were for a moment allowed to return to their leadership, that is just the question.

If, then, we try to lay before the readers of *The Tribune* the causes which, while they necessitated the German Revolution of 1848, led quite as inevitably to its momentary repression in 1849 and 1850, we shall not be expected to give a complete history of events as they passed in that country. Later events, and the judgment of coming generations, will decide what portion of that confused mass of seemingly accidental, incoherent, and incongruous facts is to form a part of the world’s history. The time for such

a task has not yet arrived; we must confine ourselves to the limits of the possible, and be satisfied, if we can find rational causes, based upon undeniable facts, to explain the chief events, the principal vicissitudes of that movement, and to give us a clue as to the direction which the next, and perhaps not very distant, outbreak will impart to the German people.

And firstly, what was the state of Germany at the outbreak of the Revolution?

The composition of the different classes of the people which form the groundwork of every political organization was, in Germany, more complicated than in any other country. While in England and France feudalism was entirely destroyed, or, at least, reduced, as in the former country, to a few insignificant forms, by a powerful and wealthy middle class, concentrated in large towns, and particularly in the capital, the feudal nobility in Germany had retained a great portion of their ancient privileges. The feudal system of tenure was prevalent almost everywhere. The lords of the land had even retained the jurisdiction over their tenants. Deprived of their political privileges, of the right to control the princes, they had preserved almost all their Mediæval supremacy over the peasantry of their demesnes, as well as their exemption from taxes. Feudalism was more flourishing in some localities than in others, but nowhere except on the left bank of the Rhine was it entirely destroyed. This feudal nobility, then extremely numerous and partly very wealthy, was considered, officially, the first "Order" in the country. It furnished the higher Government officials, it almost exclusively officered the army.

The bourgeoisie of Germany was by far not as wealthy and concentrated as that of France or England. The ancient manufactures of Germany had been destroyed by the introduction of steam, and the rapidly extending supremacy of English manufactures; the more modern manufactures, started under the Napoleonic continental system, established in other parts of the country, did not compensate for the loss of the old ones, nor suffice to create a manufacturing interest strong enough to force its wants upon the notice of Governments jealous of every extension of non-noble wealth and power. If France carried her silk manufactures victorious through fifty years of revolutions and wars, Germany, during the same time, all but lost her ancient linen trade. The manufacturing districts, besides, were few and far between; situated far inland, and using, mostly, foreign, Dutch, or Belgian ports for their imports and exports, they had little or no interest in common

with the large seaport towns on the North Sea and the Baltic; they were, above all, unable to create large manufacturing and trading centres, such as Paris and Lyons, London and Manchester. The causes of this backwardness of German manufactures were manifold, but two will suffice to account for it: the unfavorable geographical situation of the country, at a distance from the Atlantic, which had become the great highway for the world's trade, and the continuous wars in which Germany was involved, and which were fought on her soil, from the sixteenth century to the present day. It was this want of numbers, and particularly of anything like concentrated numbers, which prevented the German middle classes from attaining that political supremacy which the English bourgeoisie has enjoyed ever since 1688, and which the French conquered in 1789. And yet, ever since 1815, the wealth, and with the wealth the political importance of the middle class in Germany, was continually growing. Governments were, although reluctantly, compelled to bow, at least to its more immediate material interests. It may even be truly said that from 1815 to 1830, and from 1832 to 1840, every particle of political influence, which, having been allowed to the middle class in the constitutions of the smaller States, was again wrested from them during the above two periods of political reaction, that every such particle was compensated for by some more practical advantage allowed to them. Every political defeat of the middle class drew after it a victory on the field of commercial legislation. And certainly, the Prussian Protective Tariff of 1818, and the formation of the Zollverein, were worth a good deal more to the traders and manufacturers of Germany than the equivocal right of expressing in the chambers of some diminutive dukedom their want of confidence in ministers who laughed at their votes. Thus, with growing wealth and extending trade, the bourgeoisie soon arrived at a stage where it found the development of its most important interests checked by the political constitution of the country; by its random division among thirty-six princes with conflicting tendencies and caprices; by the feudal fetters upon agriculture and the trade connected with it; by the prying superintendence to which an ignorant and presumptuous bureaucracy subjected all its transactions. At the same time the extension and consolidation of the Zollverein, the general introduction of steam communication, the growing competition in the home trade, brought the commercial classes of the different States and Provinces closer together, equalized their interests and centralized their strength. The natural

consequence was the passing of the whole mass of them into the camp of the Liberal Opposition, and the gaining of the first serious struggle of the German middle class for political power. This change may be dated from 1840, from the moment when the bourgeoisie of Prussia assumed the lead of the middle class movement of Germany. We shall hereafter revert to this Liberal Opposition movement of 1840-1847.

The great mass of the nation, which neither belonged to the nobility nor to the bourgeoisie, consisted in the towns of the small trading and shopkeeping class and the working people, and in the country of the peasantry.

The small trading and shopkeeping class is exceedingly numerous in Germany, in consequence of the stunted development which the large capitalists and manufacturers as a class have had in that country. In the larger towns it forms almost the majority of the inhabitants; in the smaller ones it entirely predominates, from the absence of wealthier competitors or influence. This class, a most important one in every modern body politic, and in all modern revolutions, is still more important in Germany, where, during the recent struggles, it generally played the decisive part. Its intermediate position between the class of larger capitalists, traders, and manufacturers, the bourgeoisie properly so-called, and the proletarian or industrial class, determines its character. Aspiring to the position of the first, the least adverse turn of fortune hurls the individuals of this class down into the ranks of the second. In monarchical and feudal countries the custom of the court and aristocracy becomes necessary to its existence; the loss of this custom might ruin a great part of it. In the smaller towns a military garrison, a county government, a court of law with its followers, form very often the base of its prosperity; withdraw these, and down go the shopkeepers, the tailors, the shoemakers, the joiners. Thus eternally tossed about between the hope of entering the ranks of the wealthier class, and the fear of being reduced to the state of proletarians or even paupers; between the hope of promoting their interests by conquering a share in the direction of public affairs, and the dread of rousing, by ill-timed opposition, the ire of a Government which disposes of their very existence, because it has the power of removing their best customers; possessed of small means, the insecurity of the possession of which is in the inverse ratio of the amount, — this class is extremely vacillating in its views. Humble and crouchingly submissive under a powerful feudal or monarchical Government, it turns to

the side of Liberalism when the middle class is in the ascendant; it becomes seized with violent democratic fits as soon as the middle class has secured its own supremacy, but falls back into the abject despondency of fear as soon as the class below itself, the proletarians, attempts an independent movement. We shall by and by see this class, in Germany, pass alternately from one of these stages to the other.

The working class in Germany is, in its social and political development, as far behind that of England and France as the German bourgeoisie is behind the bourgeoisie of those countries. Like master, like man. The evolution of the conditions of existence for a numerous, strong, concentrated, and intelligent proletarian class goes hand in hand with the development of the conditions of existence for a numerous, wealthy, concentrated, and powerful middle class. The working class movement itself never is independent, never is of an exclusively proletarian character until all the different factions of the middle class, and particularly its most progressive faction, the large manufacturers, have conquered political power, and remodelled the State according to their wants. It is then that the inevitable conflict between the employer and the employed becomes imminent, and cannot be adjourned any longer; that the working class can no longer be put off with delusive hopes and promises never to be realized; that the great problem of the nineteenth century, the abolition of the proletariat, is at last brought forward fairly and in its proper light. Now, in Germany the mass of the working class were employed, not by those modern manufacturing lords of which Great Britain furnishes such splendid specimens, but by small tradesmen, whose entire manufacturing system is a mere relic of the Middle Ages. And as there is an enormous difference between the great cotton lord and the petty cobbler or master tailor, so there is a corresponding distance from the wide-awake factory operative of modern manufacturing Babylons to the bashful journeyman tailor or cabinetmaker of a small country town, who lives in circumstances and works after a plan very little different from those of the like sort of men some five hundred years ago. This general absence of modern conditions of life, of modern modes of industrial production, of course was accompanied by a pretty equally general absence of modern ideas, and it is, therefore, not to be wondered at if, at the outbreak of the Revolution, a large part of the working classes should cry out for the immediate re-establishment of guilds and Mediæval privileged trades' corporations. Yet from the manufacturing

districts, where the modern system of production predominated, and in consequence of the facilities of inter-communication and mental development afforded by the migratory life of a large number of the working men, a strong nucleus formed itself, whose ideas about the emancipation of their class were far clearer and more in accordance with existing facts and historical necessities; but they were a mere minority. If the active movement of the middle class may be dated from 1840, that of the working class commences its advent by the insurrections of the Silesian and Bohemian factory operatives in 1844, and we shall soon have occasion to pass in review the different stages through which this movement passed.

Lastly, there was the great class of the small farmers, the peasantry, which with its appendix of farm laborers, constitutes a considerable majority of the entire nation. But this class again sub-divided itself into different fractions. There were, firstly, the more wealthy farmers, what is called in Germany *Gross* and *Mittel-Bauern*, proprietors of more or less extensive farms, and each of them commanding the services of several agricultural laborers. This class, placed between the large untaxed feudal landowners, and the smaller peasantry and farm laborers, for obvious reasons found in an alliance with the anti-feudal middle class of the towns its most natural political course. Then there were, secondly, the small freeholders, predominating in the Rhine country, where feudalism had succumbed before the mighty strokes of the great French Revolution. Similar independent small freeholders also existed here and there in other provinces, where they had succeeded in buying off the feudal charges formerly due upon their lands. This class, however, was a class of freeholders by name only, their property being generally mortgaged to such an extent, and under such onerous conditions, that not the peasant, but the usurer who had advanced the money, was the real landowner. Thirdly, the feudal tenants, who could not be easily turned out of their holdings, but who had to pay a perpetual rent, or to perform in perpetuity a certain amount of labor in favor of the lord of the manor. Lastly, the agricultural laborers, whose condition, in many large farming concerns, was exactly that of the same class in England, and who in all cases lived and died poor, ill-fed, and the slaves of their employers. These three latter classes of the agricultural population, the small freeholders, the feudal tenants, and the agricultural laborers, never troubled their heads much about politics before the Revolution, but it is evident that this event must have opened to them a new

career, full of brilliant prospects. To every one of them the Revolution offered advantages, and the movement once fairly engaged in, it was to be expected that each, in their turn, would join it. But at the same time it is quite as evident, and equally borne out by the history of all modern countries, that the agricultural population, in consequence of its dispersion over a great space, and of the difficulty of bringing about an agreement among any considerable portion of it, never can attempt a successful independent movement; they require the initiatory impulse of the more concentrated, more enlightened, more easily moved people of the towns.

The preceding short sketch of the most important of the classes, which in their aggregate formed the German nation at the outbreak of the recent movements, will already be sufficient to explain a great part of the incoherence, incongruence, and apparent contradiction which prevailed in that movement. When interests so varied, so conflicting, so strangely crossing each other, are brought into violent collision; when these contending interests in every district, every province, are mixed in different proportions; when, above all, there is no great centre in the country, no London, no Paris, the decisions of which, by their weight, may supersede the necessity of fighting out the same quarrel over and over again in every single locality; what else is to be expected but that the contest will dissolve itself into a mass of unconnected struggles, in which an enormous quantity of blood, energy, and capital is spent, but which for all that remain without any decisive results?

The political dismemberment of Germany into three dozen of more or less important principalities is equally explained by this confusion and multiplicity of the elements which compose the nation, and which again vary in every locality. Where there are no common interests there can be no unity of purpose, much less of action. The German Confederation, it is true, was declared everlastingly indissoluble; yet the Confederation, and its organ, the Diet, never represented German unity. The very highest pitch to which centralization was ever carried in Germany was the establishment of the Zollverein; by this the States on the North Sea were also forced into a Customs Union of their own, Austria remaining wrapped up in her separate prohibitive tariff. Germany had the satisfaction to be, for all practical purposes divided between three independent powers only, instead of between thirty-six. Of course the paramount supremacy of the Russian Czar, as established in 1814, underwent no change on this account.

Having drawn these preliminary conclusions from our premises, we shall see, in our next, how the aforesaid various classes of the German people were set into movement one after the other, and what character the movement assumed on the outbreak of the French Revolution of 1848.

London, September, 1851.

II. THE PRUSSIAN STATE.

October 28th, 1851.

The political movement of the middle class or bourgeoisie, in Germany, may be dated from 1840. It had been preceded by symptoms showing that the moneyed and industrial class of that country was ripening into a state which would no longer allow it to continue apathetic and passive under the pressure of a half-feudal, half-bureaucratic Monarchism. The smaller princes of Germany, partly to insure to themselves a greater independence against the supremacy of Austria and Prussia, or against the influence of the nobility of their own States, partly in order to consolidate into a whole the disconnected provinces united under their rule by the Congress of Vienna, one after the other granted constitutions of a more or less liberal character. They could do so without any danger to themselves; for if the Diet of the Confederation, this mere puppet of Austria and Prussia, was to encroach upon their independence as sovereigns, they knew that in resisting its dictates they would be backed by public opinion and the Chambers; and if, on the contrary, these Chambers grew too strong, they could readily command the power of the Diet to break down all opposition. The Bavarian, Würtemberg, Baden or Hanoverian Constitutional institutions could not, under such circumstances, give rise to any serious struggle for political power, and, therefore, the great bulk of the German middle class kept very generally aloof from the petty squabbles raised in the Legislatures of the small States, well knowing that without a fundamental change in the policy and constitution of the two great powers of Germany, no secondary efforts and victories would be of any avail. But, at the same time, a race of Liberal lawyers, professional oppositionists, sprung up in these small assemblies: the Rottecks, the Welckers, the Roemers, the Jordans, the Stüves, the Eisenmanns, those great “popular men” (*Volksmänner*) who, after a more or less noisy, but always unsuccessful, opposition of twenty years, were carried to the summit of power by the revolutionary springtide of 1848, and who, after having there shown their utter impotency and insignificance, were hurled down again in a moment. These first specimen upon German soil of the trader in politics and opposition, by their speeches and writings made familiar to the German ear the language of Constitutionalism, and by

their very existence foreboded the approach of a time when the middle class would seize upon and restore to their proper meaning political phrases which these talkative attorneys and professors were in the habit of using without knowing much about the sense originally attached to them.

German literature, too, labored under the influence of the political excitement into which all Europe had been thrown by the events of 1830. A crude Constitutionalism, or a still cruder Republicanism, were preached by almost all writers of the time. It became more and more the habit, particularly of the inferior sorts of literati, to make up for the want of cleverness in their productions, by political allusions which were sure to attract attention. Poetry, novels, reviews, the drama, every literary production teemed with what was called "tendency," that is with more or less timid exhibitions of an anti-governmental spirit. In order to complete the confusion of ideas reigning after 1830 in Germany, with these elements of political opposition there were mixed up ill-digested university-recollections of German philosophy, and misunderstood gleanings from French Socialism, particularly Saint-Simonism; and the clique of writers who expatiated upon this heterogeneous conglomerate of ideas, presumptuously called themselves "Young Germany," or "the Modern School." They have since repented their youthful sins, but not improved their style of writing.

Lastly, German philosophy, that most complicated, but at the same time most sure thermometer of the development of the German mind, had declared for the middle class, when Hegel in his "Philosophy of Law" pronounced Constitutional Monarchy to be the final and most perfect form of government. In other words, he proclaimed the approaching advent of the middle classes of the country to political power. His school, after his death, did not stop here. While the more advanced section of his followers, on one hand, subjected every religious belief to the ordeal of a rigorous criticism, and shook to its foundation the ancient fabric of Christianity, they at the same time brought forward bolder political principles than hitherto it had been the fate of German ears to hear expounded, and attempted to restore to glory the memory of the heroes of the first French Revolution. The abstruse philosophical language in which these ideas were clothed, if it obscured the mind of both the writer and the reader, equally blinded the eyes of the censor, and thus it was that the "young Hegelian" writers enjoyed a liberty of the Press unknown in every other branch of literature.

Thus it was evident that public opinion was undergoing a great change in Germany. By degrees the vast majority of those classes whose education or position in life enabled them, under an Absolute Monarchy, to gain some political information, and to form anything like an independent political opinion, united into one mighty phalanx of opposition against the existing system. And in passing judgment upon the slowness of political development in Germany no one ought to omit taking into account the difficulty of obtaining correct information upon any subject in a country where all sources of information were under the control of the Government, where from the Ragged School and the Sunday School to the Newspaper and University nothing was said, taught, printed, or published but what had previously obtained its approbation. Look at Vienna, for instance. The people of Vienna, in industry and manufactures, second to none perhaps in Germany; in spirit, courage, and revolutionary energy, proving themselves far superior to all, were yet more ignorant as to their real interests, and committed more blunders during the Revolution than any others, and this was due in a very great measure to the almost absolute ignorance with regard to the very commonest political subjects in which Metternich's Government had succeeded in keeping them.

It needs no further explanation why, under such a system, political information was an almost exclusive monopoly of such classes of society as could afford to pay for its being smuggled into the country, and more particularly of those whose interests were most seriously attacked by the existing state of things, namely, the manufacturing and commercial classes. They, therefore, were the first to unite in a mass against the continuance of a more or less disguised Absolutism, and from their passing into the ranks of the opposition must be dated the beginning of the real revolutionary movement in Germany.

The oppositional pronunciamento of the German bourgeoisie may be dated from 1840, from the death of the late King of Prussia, the last surviving founder of the Holy Alliance of 1815. The new King was known to be no supporter of the predominantly bureaucratic and military monarchy of his father. What the French middle class had expected from the advent of Louis XVI., the German bourgeoisie hoped, in some measure, from Frederick William IV. of Prussia. It was agreed upon all hands that the old system was exploded, worn-out, and must be given up; and what had been

borne in silence under the old King now was loudly proclaimed to be intolerable.

But if Louis XVI., “Louis le Désiré,” had been a plain, unpretending simpleton, half conscious of his own nullity, without any fixed opinions, ruled principally by the habits contracted during his education, “Frederick William le Désiré” was something quite different. While he certainly surpassed his French original in weakness of character, he was neither without pretensions nor without opinions. He had made himself acquainted, in an amateur sort of way, with the rudiments of most sciences, and thought himself, therefore, learned enough to consider final his judgment upon every subject. He made sure he was a first-rate orator, and there was certainly no commercial traveller in Berlin who could beat him either in prolixity of pretended wit, or in fluency of elocution. And, above all, he had his opinions. He hated and despised the bureaucratic element of the Prussian Monarchy, but only because all his sympathies were with the feudal element. Himself one of the founders of, and chief contributors to, the *Berlin Political Weekly Paper*, the so-called Historical School (a school living upon the ideas of Bonald, De Maistre, and other writers of the first generation of French Legitimists), he aimed at a restoration, as complete as possible, of the predominant social position of the nobility. The King, first nobleman of his realm, surrounded in the first instance by a splendid court of mighty vassals, princes, dukes, and counts; in the second instance, by a numerous and wealthy lower nobility; ruling according to his discretion over his loyal burgesses and peasants, and thus being himself the chief of a complete hierarchy of social ranks or castes, each of which was to enjoy its particular privileges, and to be separated from the others by the almost insurmountable barrier of birth, or of a fixed, inalterable social position; the whole of these castes, or “estates of the realm” balancing each other at the same time so nicely in power and influence that a complete independence of action should remain to the King — such was the *beau idéal* which Frederick William IV. undertook to realize, and which he is again trying to realize at the present moment.

It took some time before the Prussian bourgeoisie, not very well versed in theoretical questions, found out the real purport of their King’s tendency. But what they very soon found out was the fact that he was bent upon things quite the reverse of what they wanted. Hardly did the new King find his “gift of the gab” unfettered by his father’s death than he set about

proclaiming his intentions in speeches without number; and every speech, every act of his, went far to estrange from him the sympathies of the middle class. He would not have cared much for that, if it had not been for some stern and startling realities which interrupted his poetic dreams. Alas, that romanticism is not very quick at accounts, and that feudalism, ever since Don Quixote, reckons without its host! Frederick William IV. partook too much of that contempt of ready cash which ever has been the noblest inheritance of the sons of the Crusaders. He found at his accession a costly, although parsimoniously arranged system of government, and a moderately filled State Treasury. In two years every trace of a surplus was spent in court festivals, royal progresses, largesses, subventions to needy, seedy, and greedy noblemen, etc., and the regular taxes were no longer sufficient for the exigencies of either Court or Government. And thus His Majesty found himself very soon placed between a glaring deficit on one side, and a law of 1820 on the other, by which any new loan, or any increase of the then existing taxation was made illegal without the assent of "the future Representation of the People." This representation did not exist; the new King was less inclined than even his father to create it; and if he had been, he knew that public opinion had wonderfully changed since his accession.

Indeed, the middle classes, who had partly expected that the new King would at once grant a Constitution, proclaim the Liberty of the Press, Trial by Jury, etc., etc. — in short, himself take the lead of that peaceful revolution which they wanted in order to obtain political supremacy — the middle classes had found out their error, and had turned ferociously against the King. In the Rhine Provinces, and more or less generally all over Prussia, they were so exasperated that they, being short themselves of men able to represent them in the Press, went to the length of an alliance with the extreme philosophical party, of which we have spoken above. The fruit of this alliance was the *Rhenish Gazette* of Cologne, a paper which was suppressed after fifteen months' existence, but from which may be dated the existence of the Newspaper Press in Germany. This was in 1842.

The poor King, whose commercial difficulties were the keenest satire upon his Mediæval propensities, very soon found out that he could not continue to reign without making some slight concession to the popular outcry for that "Representation of the People," which, as the last remnant of the long-forgotten promises of 1813 and 1815, had been embodied in the law of 1820. He found the least objectionable mode of satisfying this

untoward law in calling together the Standing Committees of the Provincial Diets. The Provincial Diets had been instituted in 1823. They consisted for every one of the eight provinces of the kingdom: — (1) Of the higher nobility, the formerly sovereign families of the German Empire, the heads of which were members of the Diet by birthright. (2) Of the representatives of the knights, or lower nobility. (3) Of representatives of towns. (4) Of deputies of the peasantry, or small farming class. The whole was arranged in such a manner that in every province the two sections of the nobility always had a majority of the Diet. Every one of these eight Provincial Diets elected a Committee, and these eight Committees were now called to Berlin in order to form a Representative Assembly for the purpose of voting the much-desired loan. It was stated that the Treasury was full, and that the loan was required, not for current wants, but for the construction of a State railway. But the united Committees gave the King a flat refusal, declaring themselves incompetent to act as the representatives of the people, and called upon His Majesty to fulfil the promise of a Representative Constitution which his father had given, when he wanted the aid of the people against Napoleon.

The sitting of the united Committees proved that the spirit of opposition was no longer confined to the bourgeoisie. A part of the peasantry had joined them, and many nobles, being themselves large farmers on their own properties, and dealers in corn, wool, spirits, and flax, requiring the same guarantees against absolutism, bureaucracy, and feudal restoration, had equally pronounced against the Government, and for a Representative Constitution. The King's plan had signally failed; he had got no money, and had increased the power of the opposition. The subsequent sitting of the Provincial Diets themselves was still more unfortunate for the King. All of them asked for reforms, for the fulfilment of the promises of 1813 and 1815, for a Constitution and a Free Press; the resolutions to this effect of some of them were rather disrespectfully worded, and the ill-humored replies of the exasperated King made the evil still greater.

In the meantime, the financial difficulties of the Government went on increasing. For a time, abatements made upon the moneys appropriated for the different public services, fraudulent transactions with the "Seehandlung," a commercial establishment speculating and trading for account and risk of the State, and long since acting as its money-broker, had sufficed to keep up appearances; increased issues of State paper-money had

furnished some resources; and the secret, upon the whole, had been pretty well kept. But all these contrivances were soon exhausted. There was another plan tried: the establishment of a bank, the capital of which was to be furnished partly by the State and partly by private shareholders; the chief direction to belong to the State, in such a manner as to enable the Government to draw upon the funds of this bank to a large amount, and thus to repeat the same fraudulent transactions that would no longer do with the "Seehandlung." But, as a matter of course, there were no capitalists to be found who would hand over their money upon such conditions; the statutes of the bank had to be altered, and the property of the shareholders guaranteed from the encroachments of the Treasury, before any shares were subscribed for. Thus, this plan having failed, there remained nothing but to try a loan, if capitalists could be found who would lend their cash without requiring the permission and guarantee of that mysterious "future Representation of the People." Rothschild was applied to, and he declared that if the loan was to be guaranteed by this "Representation of the People," he would undertake the thing at a moment's notice — if not, he could not have anything to do with the transaction.

Thus every hope of obtaining money had vanished, and there was no possibility of escaping the fatal "Representation of the People." Rothschild's refusal was known in autumn, 1846, and in February of the next year the King called together all the eight Provincial Diets to Berlin, forming them into one "United Diet." This Diet was to do the work required, in case of need, by the law of 1820; it was to vote loans and increased taxes, but beyond that it was to have no rights. Its voice upon general legislation was to be merely consultative; it was to assemble, not at fixed periods, but whenever it pleased the King; it was to discuss nothing but what the Government pleased to lay before it. Of course, the members were very little satisfied with the part they were expected to perform. They repeated the wishes they had enounced when they met in the provincial assemblies; the relations between them and the Government soon became acrimonious, and when the loan, which was again stated to be required for railway constructions, was demanded from them, they again refused to grant it.

This vote very soon brought their sitting to a close. The King, more and more exasperated, dismissed them with a reprimand, but still remained without money. And, indeed, he had every reason to be alarmed at his

position, seeing that the Liberal League, headed by the middle classes, comprising a large part of the lower nobility, and all the different sections of the lower orders — that this Liberal League was determined to have what it wanted. In vain the King had declared, in the opening speech, that he would never, never grant a Constitution in the modern sense of the word; the Liberal League insisted upon such a modern, anti-feudal, Representative Constitution, with all its sequels, Liberty of the Press, Trial by Jury, etc.; and before they got it, not a farthing of money would they grant. There was one thing evident: that things could not go on long in this manner, and that either one of the parties must give way, or that a rupture — a bloody struggle — must ensue. And the middle classes knew that they were on the eve of a revolution, and they prepared themselves for it. They sought to obtain by every possible means the support of the working class of the towns, and of the peasantry in the agricultural districts, and it is well known that there was, in the latter end of 1847, hardly a single prominent political character among the bourgeoisie who did not proclaim himself a “Socialist,” in order to insure to himself the sympathy of the proletarian class. We shall see these “Socialists” at work by and by.

This eagerness of the leading bourgeoisie to adopt, at least the outward show of Socialism, was caused by a great change that had come over the working classes of Germany. There had been ever since 1840 a fraction of German workmen, who, travelling in France and Switzerland, had more or less imbibed the crude Socialist or Communist notions then current among the French workmen. The increasing attention paid to similar ideas in France ever since 1840 made Socialism and Communism fashionable in Germany also, and as far back as 1843, all newspapers teemed with discussions of social questions. A school of Socialists very soon formed itself in Germany, distinguished more for the obscurity than for the novelty of its ideas; its principal efforts consisted in the translation of French Fourierist, Saint-Simonian, and other doctrines into the abstruse language of German philosophy. The German Communist school, entirely different from this sect, was formed about the same time.

In 1844, there occurred the Silesian weavers’ riots, followed by the insurrection of the calico printers of Prague. These riots, cruelly suppressed, riots of working men not against the Government, but against their employers, created a deep sensation, and gave a new stimulus to Socialist and Communist propaganda amongst the working people. So did the bread

riots during the year of famine, 1847. In short, in the same manner as Constitutional Opposition rallied around its banner the great bulk of the propertied classes (with the exception of the large feudal land-holders), so the working classes of the larger towns looked for their emancipation to the Socialist and Communist doctrines, although, under the then existing Press laws, they could be made to know only very little about them. They could not be expected to have any very definite ideas as to what they wanted; they only knew that the programme of the Constitutional bourgeoisie did not contain all they wanted, and that their wants were no wise contained in the Constitutional circle of ideas.

There was then no separate Republican party in Germany. People were either Constitutional Monarchists, or more or less clearly defined Socialists or Communists.

With such elements the slightest collision must have brought about a great revolution. While the higher nobility and the older civil and military officers were the only safe supports of the existing system; while the lower nobility, the trading middle classes, the universities, the school-masters of every degree, and even part of the lower ranks of the bureaucracy and military officers were all leagued against the Government; while behind these there stood the dissatisfied masses of the peasantry, and of the proletarians of the large towns, supporting, for the time being, the Liberal Opposition, but already muttering strange words about taking things into their own hands; while the bourgeoisie was ready to hurl down the Government, and the proletarians were preparing to hurl down the bourgeoisie in its turn; this Government went on obstinately in a course which must bring about a collision. Germany was, in the beginning of 1848, on the eve of a revolution, and this revolution was sure to come, even had the French Revolution of February not hastened it.

What the effects of this Parisian Revolution were upon Germany we shall see in our next.

London, September, 1851.

III. THE OTHER GERMAN STATES.

November 6th, 1851.

In our last we confined ourselves almost exclusively to that State which, during the years 1840 to 1848, was by far the most important in the German movement, namely, to Prussia. It is, however, time to pass a rapid glance over the other States of Germany during the same period.

As to the petty States, they had, ever since the revolutionary movements of 1830, completely passed under the dictatorship of the Diet, that is of Austria and Prussia. The several Constitutions, established as much as a means of defence against the dictates of the larger States, as to insure popularity to their princely authors, and unity to heterogeneous Assemblies of Provinces, formed by the Congress of Vienna, without any leading principle whatever — these Constitutions, illusory as they were, had yet proved dangerous to the authority of the petty princes themselves during the exciting times of 1830 and 1831. They were all but destroyed; whatever of them was allowed to remain was less than a shadow, and it required the loquacious self-complacency of a Welcker, a Rotteck, a Dahlmann, to imagine that any results could possibly flow from the humble opposition, mingled with degrading flattery, which they were allowed to show off in the impotent Chambers of these petty States.

The more energetic portion of the middle class in these smaller States, very soon after 1840, abandoned all the hopes they had formerly based upon the development of Parliamentary government in these dependencies of Austria and Prussia. No sooner had the Prussian bourgeoisie and the classes allied to it shown a serious resolution to struggle for Parliamentary government in Prussia, than they were allowed to take the lead of the Constitutional movement over all non-Austrian Germany. It is a fact which now will not any longer be contested, that the nucleus of those Constitutionals of Central Germany, who afterwards seceded from the Frankfort National Assembly, and who, from the place of their separate meetings, were called the Gotha party, long before 1848 contemplated a plan which, with little modification, they in 1849 proposed to the representatives of all Germany. They intended a complete exclusion of Austria from the German Confederation, the establishment of a new

Confederation, with a new fundamental law, and with a Federal Parliament, of the more insignificant States into the larger ones. All this was to be carried out the moment Prussia entered into the ranks of Constitutional Monarchy, established the Liberty of the Press, assumed a policy independent from that of Russia and Austria, and thus enabled the Constitutionals of the lesser States to obtain a real control over their respective Governments. The inventor of this scheme was Professor Gervinus, of Heidelberg (Baden). Thus the emancipation of the Prussian bourgeoisie was to be the signal for that of the middle classes of Germany generally, and for an alliance, offensive and defensive of both against Russia and Austria, for Austria was, as we shall see presently, considered as an entirely barbarian country, of which very little was known, and that little not to the credit of its population; Austria, therefore, was not considered as an essential part of Germany.

As to the other classes of society, in the smaller States they followed, more or less rapidly, in the wake of their equals in Prussia. The shopkeeping class got more and more dissatisfied with their respective Governments, with the increase of taxation, with the curtailments of those political sham-privileges of which they used to boast when comparing themselves to the “slaves of despotism” in Austria and Prussia; but as yet they had nothing definite in their opposition which might stamp them as an independent party, distinct from the Constitutionalism of the higher bourgeoisie. The dissatisfaction among the peasantry was equally growing, but it is well known that this section of the people, in quiet and peaceful times, will never assert its interests and assume its position as an independent class, except in countries where universal suffrage is established. The working classes in the trades and manufactures of the towns commenced to be infected with the “poison” of Socialism and Communism, but there being few towns of any importance out of Prussia, and still fewer manufacturing districts, the movement of this class, owing to the want of centres of action and propaganda, was extremely slow in the smaller States.

Both in Prussia and in the smaller States the difficulty of giving vent to political opposition created a sort of religious opposition in the parallel movements of German Catholicism and Free Congregationalism. History affords us numerous examples where, in countries which enjoy the blessings of a State Church, and where political discussion is fettered, the profane and dangerous opposition against the worldly power is hid under

the more sanctified and apparently more disinterested struggle against spiritual despotism. Many a Government that will not allow of any of its acts being discussed, will hesitate before it creates martyrs and excites the religious fanaticism of the masses. Thus in Germany, in 1845, in every State, either the Roman Catholic or the Protestant religion, or both, were considered part and parcel of the law of the land. In every State, too, the clergy of either of those denominations, or of both, formed an essential part of the bureaucratic establishment of the Government. To attack Protestant or Catholic orthodoxy, to attack priestcraft, was then to make an underhand attack upon the Government itself. As to the German Catholics, their very existence was an attack upon the Catholic Governments of Germany, particularly Austria and Bavaria; and as such it was taken by those Governments. The Free Congregationalists, Protestant Dissenters, somewhat resembling the English and American Unitarians, openly professed their opposition to the clerical and rigidly orthodox tendency of the King of Prussia and his favourite Minister for the Educational and Clerical Department, Mr. Eickhorn. The two new sects, rapidly extending for a moment, the first in Catholic, the second in Protestant countries, had no other distinction but their different origin; as to their tenets, they perfectly agreed upon this most important point — that all definite dogmas were nugatory. This want of any definition was their very essence; they pretended to build that great temple under the roof of which all Germans might unite; they thus represented, in a religious form, another political idea of the day — that of German unity, and yet they could never agree among themselves.

The idea of German unity, which the above-mentioned sects sought to realize, at least, upon religious ground, by inventing a common religion for all Germans, manufactured expressly for their use, habits, and taste — this idea was, indeed, very widely spread, particularly in the smaller States. Ever since the dissolution of the German Empire by Napoleon, the cry for a union of all the *disjecta membra* of the German body had been the most general expression of discontent with the established order of things, and most so in the smaller States, where costliness of a court, an administration, an army, in short, the dead weight of taxation, increased in a direct ratio with the smallness and impotency of the State. But what this German unity was to be when carried out was a question upon which parties disagreed. The bourgeoisie, which wanted no serious revolutionary convulsion, were

satisfied with what we have seen they considered “practicable,” namely a union of all Germany, exclusive of Austria, under the supremacy of a Constitutional Government of Prussia; and surely, without conjuring dangerous storms, nothing more could, at that time, be done. The shopkeeping class and the peasantry, as far as these latter troubled themselves about such things, never arrived at any definition of that German unity they so loudly clamoured after; a few dreamers, mostly feudal reactionists, hoped for the re-establishment of the German Empire; some few ignorant, *soi-disant* Radicals, admiring Swiss institutions, of which they had not yet made that practical experience which afterwards most ludicrously undeceived them, pronounced for a Federated Republic; and it was only the most extreme party which, at that time, dared pronounce for a German Republic, one and indivisible. Thus, German unity was in itself a question big with disunion, discord, and, in the case of certain eventualities, even civil war.

To resume, then; this was the state of Prussia, and the smaller States of Germany, at the end of 1847. The middle class, feeling their power, and resolved not to endure much longer the fetters with which a feudal and bureaucratic despotism enchained their commercial transactions, their industrial productivity, their common action as a class; a portion of the landed nobility so far changed into producers of mere marketable commodities, as to have the same interests and to make common cause with the middle class; the smaller trading class, dissatisfied, grumbling at the taxes, at the impediments thrown in the way of their business, but without any definite plan for such reforms as should secure their position in the social and political body; the peasantry, oppressed here by feudal exactions, there by money-lenders, usurers, and lawyers; the working people of the towns infected with the general discontent, equally hating the Government and the large industrial capitalists, and catching the contagion of Socialist and Communist ideas; in short, a heterogeneous mass of opposition, springing from various interests, but more or less led on by the bourgeoisie, in the first ranks of which again marched the bourgeoisie of Prussia, and particularly of the Rhine Province. On the other hand, Governments disagreeing upon many points, distrustful of each other, and particularly of that of Prussia, upon which yet they had to rely for protection; in Prussia a Government forsaken by public opinion, forsaken by even a portion of the nobility, leaning upon an army and a bureaucracy which every day got more

infected by the ideas, and subjected to the influence, of the oppositional bourgeoisie — a Government, besides all this, penniless in the most literal meaning of the word, and which could not procure a single cent to cover its increasing deficit, but by surrendering at discretion to the opposition of the bourgeoisie. Was there ever a more splendid position for the middle class of any country, while it struggled for power against the established Government?

London, September, 1851.

IV. AUSTRIA.

November 7th, 1851.

We have now to consider Austria; that country which, up to March, 1848, was sealed up to the eyes of foreign nations almost as much as China before the late war with England.

As a matter of course, we can here take into consideration nothing but German Austria. The affairs of the Polish, Hungarian, or Italian Austrians do not belong to our subject, and as far as they, since 1848, have influenced the fate of the German Austrians, they will have to be taken into account hereafter.

The Government of Prince Metternich turned upon two hinges; firstly, to keep every one of the different nations subjected to the Austrian rule, in check, by all other nations similarly conditioned; secondly, and this always has been the fundamental principle of absolute monarchies, to rely for support upon two classes, the feudal landlords and the large stock-jobbing capitalists; and to balance, at the same time, the influence and power of either of these classes by that of the other, so as to leave full independence of action to the Government. The landed nobility, whose entire income consisted in feudal revenues of all sorts, could not but support a Government which proved their only protection against that down-trodden class of serfs upon whose spoils they lived; and whenever the less wealthy portion of them, as in Galicia, in 1846, rose in opposition against the Government, Metternich in an instant let loose upon them these very serfs, who at any rate profited by the occasion to wreak a terrible vengeance upon their more immediate oppressors. On the other hand, the large capitalists of the Exchange were chained to Metternich's Government by the vast share they had in the public funds of the country. Austria, restored to her full power in 1815 restoring and maintaining in Italy Absolute Monarchy ever since 1820, freed from part of her liabilities by the bankruptcy of 1810, had, after the peace, very soon re-established her credit in the great European money markets; and in proportion as her credit grew, she had drawn against it. Thus all the large European money-dealers had engaged considerable portions of their capital in the Austrian funds; they all of them were interested in upholding the credit of that country, and as Austrian public

credit, in order to be upheld, ever required new loans, they were obliged from time to time to advance new capital in order to keep up the credit of the securities for that which they already had advanced. The long peace after 1815, and the apparent impossibility of a thousand years old empire, like Austria, being upset, increased the credit of Metternich's Government in a wonderful ratio, and made it even independent of the good will of the Vienna bankers and stock-jobbers; for as long as Metternich could obtain plenty of money at Frankfort and Amsterdam, he had, of course, the satisfaction of seeing the Austrian capitalists at his feet. They were, besides, in every other respect at his mercy; the large profits which bankers, stock-jobbers, and Government contractors always contrive to draw out of an absolute monarchy, were compensated for by the almost unlimited power which the Government possessed over their persons and fortunes; and not the smallest shadow of an opposition was, therefore, to be expected from this quarter. Thus Metternich was sure of the support of the two most powerful and influential classes of the empire, and he possessed besides an army and a bureaucracy, which for all purposes of absolutism could not be better constituted. The civil and military officers in the Austrian service form a race of their own; their fathers have been in the service of the Kaiser, and so will their sons be; they belong to none of the multifarious nationalities congregated under the wing of the double-headed eagle; they are, and ever have been, removed from one end of the empire to the other, from Poland to Italy, from Germany to Transylvania; Hungarian, Pole, German, Roumanian, Italian, Croat, every individual not stamped with "imperial and royal authority," etc., bearing a separate national character, is equally despised by them; they have no nationality, or rather, they alone make up the really Austrian nation. It is evident what a pliable, and at the same time powerful instrument, in the hands of an intelligent and energetic chief, such a civil and military hierarchy must be.

As to the other classes of the population, Metternich, in the true spirit of a statesman of the *ancien régime*, cared little for their support. He had, with regard to them, but one policy: to draw as much as possible out of them in the shape of taxation, and at the same time, to keep them quiet. The trading and manufacturing middle class was but of slow growth in Austria. The trade of the Danube was comparatively unimportant; the country possessed but one port, Trieste, and the trade of the port was very limited. As to the manufacturers, they enjoyed considerable protection, amounting even in

most cases to the complete exclusion of all foreign competition; but this advantage had been granted to them principally with a view to increase their tax-paying capabilities, and was in a high degree counterpoised by internal restrictions on manufactures, privileges on guilds, and other feudal corporations, which were scrupulously upheld as long as they did not impede the purposes and views of the Government. The petty tradesmen were encased in the narrow bounds of these Mediæval guilds, which kept the different trades in a perpetual war of privilege against each other, and at the same time, by all but excluding individuals of the working class from the possibility of raising themselves in the social scale, gave a sort of hereditary stability to the members of those involuntary associations. Lastly, the peasant and the working man were treated as mere taxable matter, and the only care that was taken of them was to keep them as much as possible in the same conditions of life in which they then existed, and in which their fathers had existed before them. For this purpose every old, established, hereditary authority was upheld in the same manner as that of the State; the authority of the landlord over the petty tenant farmer, that of the manufacturer over the operative, of the small master over the journeyman and apprentice, of the father over the son, was everywhere rigidly maintained by the Government, and every branch of disobedience punished the same as a transgression of the law, by that universal instrument of Austrian justice — the stick.

Finally, to wind up into one comprehensive system all these attempts at creating an artificial stability, the intellectual food allowed to the nation was selected with the minutest caution, and dealt out as sparingly as possible. Education was everywhere in the hands of the Catholic priesthood, whose chiefs, in the same manner as the large feudal landowners, were deeply interested in the conservation of the existing system. The universities were organized in a manner which allowed them to produce nothing but special men, that might or might not obtain great proficiency in sundry particular branches of knowledge, but which, at all events, excluded that universal liberal education which other universities are expected to impart. There was absolutely no newspaper press, except in Hungary, and the Hungarian papers were prohibited in all other parts of the monarchy. As to general literature, its range had not widened for a century; it had narrowed again after the death of Joseph II. And all around the frontier, wherever the Austrian States touched upon a civilized country, a cordon of literary

censors was established in connection with the cordon of customhouse officials, preventing any foreign book or newspaper from passing into Austria before its contents had been twice or three times thoroughly sifted, and found pure of even the slightest contamination of the malignant spirit of the age.

For about thirty years after 1815 this system worked with wonderful success. Austria remained almost unknown to Europe, and Europe was quite as little known in Austria. The social state of every class of the population, and of the population as a whole, appeared not to have undergone the slightest change. Whatever rancour there might exist from class to class — and the existence of this rancour was for Metternich a principal condition of government, which he even fostered by making the higher classes the instruments of all Government exactions, and thus throwing the odium upon them — whatever hatred the people might bear to the inferior officials of the State, there existed, upon the whole, little or no dissatisfaction with the Central Government. The Emperor was adored, and old Francis I. seemed to be borne out by facts when, doubting of the durability of this system, he complacently added: “And yet it will hold while I live, and Metternich.”

But there was a slow underground movement going on which baffled all Metternich's efforts. The wealth and influence of the manufacturing and trading middle class increased. The introduction of machinery and steam-power in manufactures upset in Austria, as it had done everywhere else, the old relations and vital conditions of whole classes of society; it changed serfs into free men, small farmers into manufacturing operatives; it undermined the old feudal trades-corporations, and destroyed the means of existence of many of them. The new commercial and manufacturing population came everywhere into collision with the old feudal institutions. The middle classes, more and more induced by their business to travel abroad, introduced some mythical knowledge of the civilized countries situated beyond the Imperial line of customs; the introduction of railways finally accelerated both the industrial and intellectual movement. There was, too, a dangerous part in the Austrian State establishment, *viz.*, the Hungarian feudal Constitution, with its parliamentary proceedings, and its struggles of the impoverished and oppositional mass of the nobility against the Government and its allies, the magnates. Presburg, the seat of the Diet, was at the very gates of Vienna. All the elements contributed to create

among the middle classes of the towns a spirit, not exactly of opposition, for opposition was as yet impossible, but of discontent; a general wish for reforms, more of an administrative than of a constitutional nature. And in the same manner as in Prussia, a portion of the bureaucracy joined the bourgeoisie. Among this hereditary caste of officials the traditions of Joseph II. were not forgotten; the more educated functionaries of the Government, who themselves sometimes meddled with imaginary possible reforms, by far preferred the progressive and intellectual despotism of that Emperor to the “paternal” despotism of Metternich. A portion of the poorer nobility equally sided with the middle class, and as to the lower classes of the population, who always had found plenty of grounds to complain of their superiors, if not of the Government, they in most cases could not but adhere to the reformatory wishes of the bourgeoisie.

It was about this time, say 1843 or 1844, that a particular branch of literature, agreeable to this change, was established in Germany. A few Austrian writers, novelists, literary critics, bad poets, the whole of them of very indifferent ability, but gifted with that peculiar industrialism proper to the Jewish race, established themselves in Leipsic and other German towns out of Austria, and there, out of the reach of Metternich, published a number of books and pamphlets on Austrian affairs. They and their publishers made “a roaring trade” of it. All Germany was eager to become initiated into the secrets of the policy of European China; and the Austrians themselves, who obtained these publications by the wholesale smuggling carried on upon the Bohemian frontier, were still more curious. Of course, the secrets let out in these publications were of no great importance, and the reform plans schemed out by their well-wishing authors bore the stamp of an innocuousness almost amounting to political virginity. A Constitution and a free press for Austria were things considered unattainable; administrative reforms, extension of the rights of the Provincial Diets, admission of foreign books and newspapers, and a less severe censorship — the loyal and humble desires of these good Austrians did hardly go any farther.

At all events the growing impossibility of preventing the literary intercourse of Austria with the rest of Germany, and through Germany with the rest of the world, contributed much toward the formation of an anti-Governmental public opinion, and brought at least some little political information within the reach of part of the Austrian population. Thus, by the

end of 1847, Austria was seized, although in an inferior degree, by that political and politico-religious agitation which then prevailed in all Germany; and if its progress in Austria was more silent, it did, nevertheless, find revolutionary elements enough to work upon. There was the peasant, serf, or feudal tenant, ground down into the dust by lordly or Government exactions; then the factory operative, forced by the stick of the policeman to work upon any terms the manufacturer chose to grant; then the journeyman, debarred by the corporative laws from any chance of gaining an independence in his trade; then the merchant, stumbling at every step in business over absurd regulations; then the manufacturer, in uninterrupted conflict with trade-guilds, jealous of their privileges, or with greedy and meddling officials; then the school-master, the *savant*, the better educated functionary, vainly struggling against an ignorant and presumptuous clergy, or a stupid and dictating superior. In short, there was not a single class satisfied, for the small concessions Government was obliged now and then to make were not made at its own expense, for the treasury could not afford that, but at the expense of the high aristocracy and clergy; and as to the great bankers, and fundholders, the late events in Italy, the increasing opposition of the Hungarian Diet, and the unwonted spirit of discontent and cry for reform, manifesting themselves all over the Empire, were not of a nature to strengthen their faith in the solidity and solvency of the Austrian Empire.

Thus Austria, too, was marching slowly but surely toward a mighty change, when, of a sudden, an event broke out in France, which at once brought down the impending storm, and gave the lie to old Francis's assertion, that the building would hold out both during his and Metternich's lifetime.

London, September, 1851.

V. THE VIENNA INSURRECTION.

November 12, 1851.

On the 24th of February, 1848, Louis Philippe was driven out of Paris, and the French Republic was proclaimed. On the 13th of March following, the people of Vienna broke the power of Prince Metternich, and made him flee shamefully out of the country. On the 18th of March the people of Berlin rose in arms, and, after an obstinate struggle of eighteen hours, had the satisfaction of seeing the King surrender himself into their hands. Simultaneous outbreaks of a more or less violent nature, but all with the same success, occurred in the capitals of the smaller States of Germany. The German people, if they had not accomplished their first revolution, were at least fairly launched into the revolutionary career.

As to the incidents of these various insurrections, we cannot enter here into the details of them: what we have to explain is their character, and the position which the different classes of the population took up with regard to them.

The Revolution of Vienna may be said to have been made by an almost unanimous population. The bourgeoisie (with the exception of the bankers and stock-jobbers), the petty trading class, the working people, one and all arose at once against a Government detested by all, a Government so universally hated, that the small minority of nobles and money lords which had supported it made itself invisible on the very first attack. The middle classes had been kept in such a degree of political ignorance by Metternich that to them the news from Paris about the reign of Anarchy, Socialism, and terror, and about impending struggles between the class of capitalists and the class of laborers, proved quite unintelligible. They, in their political innocence, either could attach no meaning to these news, or they believed them to be fiendish inventions of Metternich, to frighten them into obedience. They, besides, had never seen working men acting as a class, or stand up for their own distinct class interests. They had, from their past experience, no idea of the possibility of any differences springing up between classes that now were so heartily united in upsetting a Government hated by all. They saw the working people agree with themselves upon all points: a Constitution, Trial by Jury, Liberty of the Press, etc. Thus they

were, in March, 1848, at least, heart and soul with the movement, and the movement, on the other hand, at once constituted them the (at least in theory) predominant class of the State.

But it is the fate of all revolutions that this union of different classes, which in some degree is always the necessary condition of any revolution, cannot subsist long. No sooner is the victory gained against the common enemy than the victors become divided among themselves into different camps, and turn their weapons against each other. It is this rapid and passionate development of class antagonism which, in old and complicated social organisms, makes a revolution such a powerful agent of social and political progress; it is this incessantly quick upshooting of new parties succeeding each other in power, which, during those violent commotions, makes a nation pass in five years over more ground than it would have done in a century under ordinary circumstances.

The Revolution in Vienna made the middle class the theoretically predominant class; that is to say, the concessions wrung from the Government were such as, once carried out practically and adhered to for a time, would inevitably have secured the supremacy of the middle class. But practically the supremacy of that class was far from being established. It is true that by the establishment of a national guard, which gave arms to the bourgeoisie and petty tradesmen, that class obtained both force and importance; it is true that by the installation of a "Committee of Safety," a sort of revolutionary, irresponsible Government in which the bourgeoisie predominated, it was placed at the head of power. But, at the same time, the working classes were partially armed too; they and the students had borne the brunt of the fight, as far as fight there had been; and the students, about 4,000 strong, well-armed, and far better disciplined than the national guard, formed the nucleus, the real strength of the revolutionary force, and were no ways willing to act as a mere instrument in the hands of the Committee of Safety. Though they recognized it, and were even its most enthusiastic supporters, they yet formed a sort of independent and rather turbulent body, deliberating for themselves in the "Aula," keeping an intermediate position between the bourgeoisie and the working-classes, preventing by constant agitation things from settling down to the old every-day tranquillity, and very often forcing their resolutions upon the Committee of Safety. The working men, on the other hand, almost entirely thrown out of employment, had to be employed in public works at the expense of the State, and the

money for this purpose had, of course, to be taken out of the purse of the tax-payers or out of the chest of the city of Vienna. All this could not but become very unpleasant to the tradesmen of Vienna. The manufactures of the city, calculated for the consumption of the rich and aristocratic courts of a large country, were as a matter of course entirely stopped by the Revolution, by the flight of the aristocracy and Court; trade was at a standstill, and the continuous agitation and excitement kept up by the students and working people was certainly not the means to “restore confidence,” as the phrase went. Thus a certain coolness very soon sprung up between the middle classes on the one side and the turbulent students and working people on the other; and if for a long time this coolness was not ripened into open hostility, it was because the Ministry, and particularly the Court, in their impatience to restore the old order of things, constantly justified the suspicions and the turbulent activity of the more revolutionary parties, and constantly made arise, even before the eyes of the middle classes, the spectre of old Metternichian despotism. Thus on the 15th of May, and again on the 16th, there were fresh risings of all classes in Vienna, on account of the Government having tried to attack, or to undermine some of the newly-conquered liberties, and on each occasion the alliance between the national guard or armed middle class, the students, and the workingmen, was again cemented for a time.

As to the other classes of the population, the aristocracy and the money lords had disappeared, and the peasantry were busily engaged everywhere in removing, down to the very last vestiges of feudalism. Thanks to the war in Italy, and the occupation which Vienna and Hungary gave to the Court, they were left at full liberty, and succeeded in their work of liberation, in Austria, better than in any other part of Germany. The Austrian Diet had very shortly after only to confirm the steps already practically taken by the peasantry, and whatever else the Government of Prince Schwarzenberg may be enabled to restore, it will never have the power of re-establishing the feudal servitude of the peasantry. And if Austria at the present moment is again comparatively tranquil, and even strong, it is principally because the great majority of the people, the peasants, have been real gainers by the Revolution, and because whatever else has been attacked by the restored Government, those palpable, substantial advantages, conquered by the peasantry, are as yet untouched.

London, October, 1851.

VI. THE BERLIN INSURRECTION.

November 28, 1851.

The second center of revolutionary action was Berlin, and from what has been stated in the foregoing papers, it may be guessed that there this action was far from having that unanimous support of almost all classes by which it was accompanied in Vienna. In Prussia, the bourgeoisie had been already involved in actual struggles with the Government; a rupture had been the result of the "United Diet"; a bourgeois revolution was impending, and that revolution might have been, in its first outbreak, quite as unanimous as that of Vienna, had it not been for the Paris Revolution of February. That event precipitated everything, while at the same time it was carried out under a banner totally different from that under which the Prussian bourgeoisie was preparing to defy its Government. The Revolution of February upset, in France, the very same sort of Government which the Prussian bourgeoisie were going to set up in their own country. The Revolution of February announced itself as a revolution of the working classes against the middle classes; it proclaimed the downfall of middle-class government and the emancipation of the workingman. Now the Prussian bourgeoisie had, of late, had quite enough of working-class agitation in their own country. After the first terror of the Silesian riots had passed away, they had even tried to give this agitation a turn in their own favor; but they always had retained a salutary horror of revolutionary Socialism and Communism; and, therefore, when they saw men at the head of the Government in Paris whom they considered as the most dangerous enemies of property, order, religion, family, and of the other *Penates* of the modern bourgeois, they at once experienced a considerable cooling down of their own revolutionary ardor. They knew that the moment must be seized, and that, without the aid of the working masses, they would be defeated; and yet their courage failed them. Thus they sided with the Government in the first partial and provincial outbreaks, tried to keep the people quiet in Berlin, who, during five days, met in crowds before the royal palace to discuss the news and ask for changes in the Government; and when at last, after the news of the downfall of Metternich, the King made some slight concessions, the bourgeoisie considered the Revolution as completed, and went to thank His Majesty for

having fulfilled all the wishes of his people. But then followed the attack of the military on the crowd, the barricades, the struggle, and the defeat of royalty. Then everything was changed; the very working classes, which it had been the tendency of the bourgeoisie to keep in the background, had been pushed forward, had fought and conquered, and all at once were conscious of their strength. Restrictions of suffrage, of the liberty of the press, of the right to sit on juries, of the right of meeting — restrictions that would have been very agreeable to the bourgeoisie because they would have touched upon such classes only as were beneath them — now were no longer possible. The danger of a repetition of the Parisian scenes of “anarchy” was imminent. Before this danger all former differences disappeared. Against the victorious workingman, although he had not yet uttered any specific demands for himself, the friends and the foes of many years united, and the alliance between the bourgeoisie and the supporters of the over-turned system was concluded upon the very barricades of Berlin. The necessary concessions, but no more than was unavoidable, were to be made, a ministry of the opposition leaders of the United Diet was to be formed, and in return for its services in saving the Crown, it was to have the support of all the props of the old Government, the feudal aristocracy, the bureaucracy, the army. These were the conditions upon which Messrs. Camphausen and Hansemann undertook the formation of a cabinet.

Such was the dread evinced by the new ministers of the aroused masses, that in their eyes every means was good if it only tended to strengthen the shaken foundations of authority. They, poor deluded wretches, thought every danger of a restoration of the old system had passed away; and thus they made use of the whole of the old State machinery for the purpose of restoring “order.” Not a single bureaucrat or military officer was dismissed; not the slightest change was made in the old bureaucratic system of administration. These precious constitutional and responsible ministers even restored to their posts those functionaries whom the people, in the first heat of revolutionary ardor, had driven away on account of their former acts of bureaucratic overbearing. There was nothing altered in Prussia but the persons of the ministers; even the ministerial staffs in the different departments were not touched upon, and all the constitutional place-hunters, who had formed the chorus of the newly-elevated rulers, and who had expected their share of power and office, were told to wait until restored

stability allowed changes to be operated in the bureaucratic personnel which now were not without danger.

The King, chap-fallen in the highest degree after the insurrection of the 18th of March, very soon found out that he was quite as necessary to these “liberal” ministers as they were to him. The throne had been spared by the insurrection; the throne was the last existing obstacle to “anarchy”; the liberal middle class and its leaders, now in the ministry, had therefore every interest to keep on excellent terms with the crown. The King, and the reactionary camerilla that surrounded him, were not slow in discovering this, and profited by the circumstance in order to fetter the march of the ministry even in those petty reforms that were from time to time intended.

The first care of the ministry was to give a sort of legal appearance to the recent violent changes. The United Diet was convoked in spite of all popular opposition, in order to vote as the legal and constitutional organ of the people a new electoral law for the election of an Assembly, which was to agree with the crown upon a new constitution. The elections were to be indirect, the mass of voters electing a number of electors, who then were to choose the representative. In spite of all opposition this system of double elections passed. The United Diet was then asked for a loan of twenty-five millions of dollars, opposed by the popular party, but equally agreed to.

These acts of the ministry gave a most rapid development to the popular, or as it now called itself, the Democratic party. This party, headed by the petty trading and shopkeeping class, and uniting under its banner, in the beginning of the revolution, the large majority of the working people, demanded direct and universal suffrage, the same as established in France, a single legislative assembly, and full and open recognition of the revolution of the 18th of March, as the base of the new governmental system. The more moderate faction would be satisfied with a thus “democratized” monarchy, the more advanced demanded the ultimate establishment of the republic. Both factions agreed in recognizing the German National Assembly at Frankfort as the supreme authority of the country, while the Constitutionals and Reactionists affected a great horror of the sovereignty of this body, which they professed to consider as utterly revolutionary.

The independent movement of the working classes had, by the revolution, been broken up for a time. The immediate wants and circumstances of the movement were such as not to allow any of the specific demands of the Proletarian party to be put in the foreground. In

fact, as long as the ground was not cleared for the independent action of the working men, as long as direct and universal suffrage was not yet established, as long as the thirty-six larger and smaller states continued to cut up Germany into numberless morsels, what else could the Proletarian party do but watch the — for them all-important — movement of Paris, and struggle in common with the petty shopkeepers for the attainment of those rights, which would allow them to fight afterwards their own battle?

There were only three points, then, by which the Proletarian party in its political action essentially distinguished itself from the petty trading class, or properly so-called Democratic party; firstly, in judging differently the French movement, with regard to which the democrats attacked, and the Proletarian revolutionists defended, the extreme party in Paris; secondly, in proclaiming the necessity of establishing a German Republic, one and indivisible, while the very extremest ultras among the democrats only dared to sigh for a Federative Republic; and thirdly, in showing upon every occasion, that revolutionary boldness and readiness for action, in which any party headed by, and composed principally of petty tradesmen, will always be deficient.

The Proletarian, or really Revolutionary party, succeeded only very gradually in withdrawing the mass of the working people from the influence of the Democrats, whose tail they formed in the beginning of the Revolution. But in due time the indecision, weakness, and cowardice of the Democratic leaders did the rest, and it may now be said to be one of the principal results of the last years' convulsions, that wherever the working-class is concentrated in anything like considerable masses, they are entirely freed from that Democratic influence which led them into an endless series of blunders and misfortunes during 1848 and 1849. But we had better not anticipate; the events of these two years will give us plenty of opportunities to show the Democratic gentlemen at work.

The peasantry in Prussia, the same as in Austria, but with less energy, feudalism pressing, upon the whole, not quite so hardly upon them here, had profited by the revolution to free themselves at once from all feudal shackles. But here, from the reasons stated before, the middle classes at once turned against them, their oldest, their most indispensable allies; the democrats, equally frightened with the bourgeoisie, by what was called attacks upon private property, failed equally to support them; and thus, after three months' emancipation, after bloody struggles and military executions,

particularly in Silesia, feudalism was restored by the hands of the, until yesterday, anti-feudal bourgeoisie. There is not a more damning fact to be brought against them than this. Similar treason against its best allies, against itself, never was committed by any party in history, and whatever humiliation and chastisement may be in store for this middle class party, it has deserved by this one act every morsel of it.

October, 1851.

VII. THE FRANKFORT NATIONAL ASSEMBLY.

February 27, 1852.

It will perhaps be in the recollection of our readers that in the six preceding papers we followed up the revolutionary movement of Germany to the two great popular victories of March 13th in Vienna, and March 18th in Berlin. We saw, both in Austria and Prussia, the establishment of constitutional governments and the proclamation, as leading rules for all future policy, of Liberal, or middle class principles; and the only difference observable between the two great centers of action was this, that in Prussia the liberal bourgeoisie, in the persons of two wealthy merchants, Messrs. Camphausen and Hansemann, directly seized upon the reins of power; while in Austria, where the bourgeoisie was, politically, far less educated, the Liberal bureaucracy walked into office, and professed to hold power in trust for them. We have further seen, how the parties and classes of society, that were heretofore all united in opposition to the old government, got divided among themselves after the victory, or even during the struggle; and how that same Liberal bourgeoisie that alone profited from the victory turned round immediately upon its allies of yesterday, assumed a hostile attitude against every class or party of a more advanced character, and concluded an alliance with the conquered feudal and bureaucratic interests. It was in fact, evident, even from the beginning of the revolutionary drama, that the Liberal bourgeoisie could not hold its ground against the vanquished, but not destroyed, feudal and bureaucratic parties except by relying upon the assistance of the popular and more advanced parties; and that it equally required, against the torrent of these more advanced masses, the assistance of the feudal nobility and of the bureaucracy. Thus, it was clear enough that the bourgeoisie in Austria and Prussia did not possess sufficient strength to maintain their power, and to adapt the institutions of the country to their own wants and ideas. The Liberal bourgeois ministry was only a halting-place from which, according to the turn circumstances might take, the country would either have to go on to the more advanced stage of Unitarian republicanism, or to relapse into the old clerico-feudal

and bureaucratic *régime*. At all events, the real, decisive struggle was yet to come; the events of March had only engaged the combat.

Austria and Prussia being the two ruling states of Germany, every decisive revolutionary victory in Vienna or Berlin would have been decisive for all Germany. And as far as they went, the events of March, 1848, in these two cities, decided the turn of German affairs. It would, then, be superfluous to recur to the movements that occurred in the minor States; and we might, indeed, confine ourselves to the consideration of Austrian and Prussian affairs exclusively, if the existence of these minor states had not given rise to a body which was, by its very existence, a most striking proof of the abnormal situation of Germany and of the incompleteness of the late revolution; a body so abnormal, so ludicrous by its very position, and yet so full of its own importance, that history will, most likely, never afford a pendant to it. This body was the so-called *German National Assembly* at Frankfort-on-Main.

After the popular victories of Vienna and Berlin, it was a matter of course that there should be a Representative Assembly for all Germany. This body was consequently elected, and met at Frankfort, by the side of the old Federative Diet. The German National Assembly was expected, by the people, to settle every matter in dispute, and to act as the highest legislative authority for the whole of the German Confederation. But, at the same time, the Diet which had convoked it had in no way fixed its attributions. No one knew whether its decrees were to have force of law, or whether they were to be subject to the sanction of the Diet, or of the individual Governments. In this perplexity, if the Assembly had been possessed of the least energy, it would have immediately dissolved and sent home the Diet — than which no corporate body was more unpopular in Germany — and replaced it by a Federal Government, chosen from among its own members. It would have declared itself the only legal expression of the sovereign will of the German people, and thus have attached legal validity to every one of its decrees. It would, above all, have secured to itself an organized and armed force in the country sufficient to put down any opposition on the parts of the Governments. And all this was easy, very easy, at that early period of the Revolution. But that would have been expecting a great deal too much from an Assembly composed in its majority of Liberal attorneys and *doctrinaire* professors, an Assembly which, while it pretended to embody the very essence of German intellect and science, was in reality nothing but a stage

where old and worn-out political characters exhibited their involuntary ludicrousness and their impotence of thought, as well as action, before the eyes of all Germany. THIS Assembly of old women was, from the first day of its existence, more frightened of the least popular movement than of all the reactionary plots of all the German Governments put together. It deliberated under the eyes of the Diet, nay, it almost craved the Diet's sanction to its decrees, for its first resolutions had to be promulgated by that odious body. Instead of asserting its own sovereignty, it studiously avoided the discussion of any such dangerous question. Instead of surrounding itself by a popular force, it passed to the order of the day over all the violent encroachments of the Governments; Mayence, under its very eyes, was placed in a state of siege, and the people there disarmed, and the National Assembly did not stir. Later on it elected Archduke John of Austria Regent of Germany, and declared that all its resolutions were to have the force of law; but then Archduke John was only instituted in his new dignity after the consent of all the Governments had been obtained, and he was instituted not by the Assembly, but by the Diet; and as to the legal force of the decrees of the Assembly, that point was never recognized by the larger Governments, nor enforced by the Assembly itself; it therefore remained in suspense. Thus we had the strange spectacle of an Assembly pretending to be the only legal representative of a great and sovereign nation, and yet never possessing either the will or the force to make its claims recognized. The debates of this body, without any practical result, were not even of any theoretical value, reproducing, as they did, nothing but the most hackneyed commonplace themes of superannuated philosophical and juridical schools; every sentence that was said, or rather stammered forth, in that Assembly having been printed a thousand times over, and a thousand times better, long before.

Thus the pretended new central authority of Germany left everything as it had found it. So far from realizing the long-demanded unity of Germany, it did not dispossess the most insignificant of the princes who ruled her; it did not draw closer the bonds of union between her separated provinces; it never moved a single step to break down the customhouse barriers that separated Hanover from Prussia, and Prussia from Austria; it did not even make the slightest attempt to remove the obnoxious dues that everywhere obstruct river navigation in Prussia. But the less this Assembly did the more it blustered. It created a German fleet — upon paper; it annexed Poland and

Schleswig; it allowed German-Austria to carry on war against Italy, and yet prohibited the Italians from following up the Austrians into their safe retreat in Germany; it gave three cheers and one cheer more for the French republic, and it received Hungarian embassies, which certainly went home with far more confused ideas about Germany than they had come with.

This Assembly had been, in the beginning of the Revolution, the bugbear of all German Governments. They had counted upon a very dictatorial and revolutionary action on its part — on account of the very want of definiteness in which it had been found necessary to leave its competency. These Governments, therefore, got up a most comprehensive system of intrigues in order to weaken the influence of this dreaded body; but they proved to have more luck than wits, for this Assembly did the work of the Governments better than they themselves could have done. The chief feature among these intrigues was the convocation of local Legislative Assemblies, and in consequence, not only the lesser States convoked their legislatures, but Prussia and Austria also called constituent assemblies. In these, as in the Frankfort House of Representatives, the Liberal middle class, or its allies, liberal lawyers, and bureaucrats had the majority, and the turn affairs took in each of them was nearly the same. The only difference is this, that the German National Assembly was the parliament of an imaginary country, as it had declined the task of forming what nevertheless was its own first condition of existence, viz. a United Germany; that it discussed the imaginary and never-to-be-carried-out measures of an imaginary government of its own creation, and that it passed imaginary resolutions for which nobody cared; while in Austria and Prussia the constituent bodies were at least real parliaments, upsetting and creating real ministries, and forcing, for a time at least, their resolutions upon the princes with whom they had to contend. They, too, were cowardly, and lacked enlarged views of revolutionary resolutions; they, too, betrayed the people, and restored power to the hands of feudal, bureaucratic, and military despotism. But then they were at least obliged to discuss practical questions of immediate interest, and to live upon earth with other people, while the Frankfort humbugs were never happier than when they could roam in “the airy realms of dream,” *im Luftreich des Traums*. Thus the proceedings of the Berlin and Vienna Constituents form an important part of German revolutionary history, while the lucubrations of the Frankfort collective

tomfoolery merely interest the collector of literary and antiquarian curiosities.

The people of Germany, deeply feeling the necessity of doing away with the obnoxious territorial division that scattered and annihilated the collective force of the nation, for some time expected to find, in the Frankfort National Assembly at least, the beginning of a new era. But the childish conduct of that set of wiseacres soon disenchanted the national enthusiasm. The disgraceful proceedings occasioned by the armistice of Malmoe (September, 1848,) made the popular indignation burst out against a body which, it had been hoped, would give the nation a fair field for action, and which, instead, carried away by unequalled cowardice, only restored to their former solidity the foundations upon which the present counter-revolutionary system is built.

London, January, 1852.

VIII. POLES, TSCHECHS, AND GERMANS.

March 5th, 1852.

From what has been stated in the foregoing articles, it is already evident that unless a fresh revolution was to follow that of March, 1848, things would inevitably return, in Germany, to what they were before this event. But such is the complicated nature of the historical theme upon which we are trying to throw some light, that subsequent events cannot be clearly understood without taking into account what may be called the foreign relations of the German Revolution. And these foreign relations were of the same intricate nature as the home affairs.

The whole of the eastern half of Germany, as far as the Elbe, Saale, and Bohemian Forest, has, it is well known, been reconquered during the last thousand years, from invaders of Slavonic origin. The greater part of these territories have been Germanized, to the perfect extinction of all Slavonic nationality and language, for several centuries past; and if we except a few totally isolated remnants, amounting in the aggregate to less than a hundred thousand souls (Kassubians in Pomerania, Wends or Sorbians in Lusatia), their inhabitants are, to all intents and purposes, Germans. But the case is different along the whole of the frontier of ancient Poland, and in the countries of the Tschechian tongue, in Bohemia and Moravia. Here the two nationalities are mixed up in every district, the towns being generally more or less German, while the Slavonic element prevails in the rural villages, where, however, it is also gradually disintegrated and forced back by the steady advance of German influence.

The reason of this state of things is this: ever since the time of Charlemagne, the Germans have directed their most constant and persevering efforts to the conquest, colonization, or, at least, civilization of the east of Europe. The conquest of the feudal nobility between the Elbe and the Oder, and the feudal colonies of the military orders of knights in Prussia and Livonia, only laid the ground for a far more extensive and effective system of Germanization by the trading and manufacturing middle classes, which in Germany, as in the rest of Western Europe, rose into social and political importance since the fifteenth century. The Slavonians, and particularly the Western Slavonians (Poles and Tschechs), are essentially an

agricultural race; trade and manufactures never were in great favor with them. The consequence was that, with the increase of population and the origin of cities in these regions, the production of all articles of manufacture fell into the hands of German immigrants, and the exchange of these commodities against agricultural produce became the exclusive monopoly of the Jews, who, if they belong to any nationality, are in these countries certainly rather Germans than Slavonians. This has been, though in a less degree, the case in all the east of Europe. The handicraftsman, the small shopkeeper, the petty manufacturer, is a German up to this day in Petersburg, Pesth, Jassy, and even Constantinople; while the money-lender, the publican, the hawker — a very important man in these thinly populated countries — is very generally a Jew, whose native tongue is a horribly corrupted German. The importance of the German element in the Slavonic frontier localities, thus rising with the growth of towns, trade and manufactures, was still increased when it was found necessary to import almost every element of mental culture from Germany; after the German merchant and handicraftsman, the German clergyman, the German school-master, the German *savant* came to establish himself upon Slavonic soil. And lastly, the iron thread of conquering armies, or the cautious, well-premeditated grasp of diplomacy, not only followed, but many times went ahead of the slow but sure advance of denationalization by social development. Thus, great parts of Western Prussia and Posen have been Germanized since the first partition of Poland, by sales and grants of public domains to German colonists, by encouragements given to German capitalists for the establishment of manufactories, etc., in those neighborhoods, and very often, too, by excessively despotic measures against the Polish inhabitants of the country.

In this manner the last seventy years had entirely changed the line of demarcation between the German and Polish nationalities. The Revolution of 1848 calling forth at once the claim of all oppressed nations to an independent existence, and to the right of settling their own affairs for themselves, it was quite natural that the Poles should at once demand the restoration of their country within the frontiers of the old Polish Republic before 1772. It is true, this frontier, even at that time, had become obsolete, if taken as the delimitation of German and Polish nationality; it had become more so every year since by the progress of Germanization; but then, the Germans had proclaimed such an enthusiasm for the restoration of Poland,

that they must expect to be asked, as a first proof of the reality of their sympathies to give up *their* share of the plunder. On the other hand, should whole tracts of land, inhabited chiefly by Germans, should large towns, entirely German, be given up to a people that as yet had never given any proofs of its capability of progressing beyond a state of feudalism based upon agricultural serfdom? The question was intricate enough. The only possible solution was in a war with Russia. The question of delimitation between the different revolutionized nations would have been made a secondary one to that of first establishing a safe frontier against the common enemy. The Poles, by receiving extended territories in the east, would have become more tractable and reasonable in the west; and Riga and Milan would have been deemed, after all, quite as important to them as Danzig and Elbing. Thus the advanced party in Germany, deeming a war with Russia necessary to keep up the Continental movement, and considering that the national re-establishment even of a part of Poland would inevitably lead to such a war, supported the Poles; while the reigning middle class partly clearly foresaw its downfall from any national war against Russia, which would have called more active and energetic men to the helm, and, therefore, with a feigned enthusiasm for the extension of German nationality, they declared Prussian Poland, the chief seat of Polish revolutionary agitation, to be part and parcel of the German Empire that was to be. The promises given to the Poles in the first days of excitement were shamefully broken. Polish armaments got up with the sanction of the Government were dispersed and massacred by Prussian artillery; and as soon as the month of April, 1848, within six weeks of the Berlin Revolution, the Polish movement was crushed, and the old national hostility revived between Poles and Germans. This immense and incalculable service to the Russian autocrat was performed by the Liberal merchant-ministers, Camphausen and Hansemann. It must be added that this Polish campaign was the first means of reorganizing and reassuring that same Prussian army, which afterward turned out the Liberal party, and crushed the movement which Messrs. Camphausen and Hansemann had taken such pains to bring about. "Whereby they sinned, thereby are they punished." Such has been the fate of all the upstarts of 1848 and 1849, from Ledru Rolin to Changarnier, and from Camphausen down to Haynau.

The question of nationality gave rise to another struggle in Bohemia. This country, inhabited by two millions of Germans, and three millions of

Slavonians of the Tschechian tongue, had great historical recollections, almost all connected with the former supremacy of the Tschechs. But then the force of this branch of the Slavonic family had been broken ever since the wars of the Hussites in the fifteenth century. The province speaking the Tschechian tongue was divided, one part forming the kingdom of Bohemia, another the principality of Moravia, a third the Carpathian hill-country of the Slovaks, being part of Hungary. The Moravians and Slovaks had long since lost every vestige of national feeling and vitality, although mostly preserving their language. Bohemia was surrounded by thoroughly German countries on three sides out of four. The German element had made great progress on her own territory; even in the capital, in Prague, the two nationalities were pretty equally matched; and everywhere capital, trade, industry, and mental culture were in the hands of the Germans. The chief champion of the Tschechian nationality, Professor Palacky, is himself nothing but a learned German run mad, who even now cannot speak the Tschechian language correctly and without foreign accent. But as it often happens, dying Tschechian nationality, dying according to every fact known in history for the last four hundred years, made in 1848 a last effort to regain its former vitality — an effort whose failure, independently of all revolutionary considerations, was to prove that Bohemia could only exist, henceforth, as a portion of Germany, although part of her inhabitants might yet, for some centuries, continue to speak a non-German language.

IX. PANSLAVISM — THE SCHLESWIG-HOLSTEIN WAR.

March 15th, 1852.

Bohemia and Croatia (another disjected member of the Slavonic family, acted upon by the Hungarian, as Bohemia by the German) were the homes of what is called on the European continent “Panslavism.” Neither Bohemia nor Croatia was strong enough to exist as a nation by herself. Their respective nationalities, gradually undermined by the action of historical causes that inevitably absorbs into a more energetic stock, could only hope to be restored to anything like independence by an alliance with other Slavonic nations. There were twenty-two millions of Poles, forty-five millions of Russians, eight millions of Serbians and Bulgarians; why not form a mighty confederation of the whole eighty millions of Slavonians, and drive back or exterminate the intruder upon the holy Slavonic soil, the Turk, the Hungarian, and above all the hated, but indispensable *Niemetz*, the German? Thus in the studies of a few Slavonian *dilettanti* of historical science was this ludicrous, this anti-historical movement got up, a movement which intended nothing less than to subjugate the civilized West under the barbarian East, the town under the country, trade, manufactures, intelligence, under the primitive agriculture of Slavonian serfs. But behind this ludicrous theory stood the terrible reality of the *Russian Empire*; that empire which by every movement proclaims the pretension of considering all Europe as the domain of the Slavonic race, and especially of the only energetic part of this race, of the Russians; that empire which, with two capitals such as St. Petersburg and Moscow, has not yet found its centre of gravity, as long as the “City of the Czar” (Constantinople, called in Russian Tzarigrad, the Czar’s city), considered by every Russian peasant as the true metropolis of his religion and his nation, is not actually the residence of its Emperor; that empire which, for the last one hundred and fifty years, has never lost, but always gained territory by every war it has commenced. And well known in Central Europe are the intrigues by which Russian policy supported the new-fangled system of Panslavism, a system than which none better could be invented to suit its purposes. Thus, the Bohemian and Croatian Panslavists, some intentionally, some without knowing it, worked

in the direct interest of Russia; they betrayed the revolutionary cause for the shadow of a nationality which, in the best of cases, would have shared the fate of the Polish nationality under Russian sway. It must, however, be said for the honor of the Poles, that they never got to be seriously entangled in these Panslavist traps, and if a few of the aristocracy turned furious Panslavists, they knew that by Russian subjugation they had less to lose than by a revolt of their own peasant serfs.

The Bohemians and Croatians called, then, a general Slavonic Congress at Prague, for the preparation of the universal Slavonian Alliance. This Congress would have proved a decided failure even without the interference of the Austrian military. The several Slavonic languages differ quite as much as the English, the German, and the Swedish, and when the proceedings opened, there was no common Slavonic tongue by which the speakers could make themselves understood. French was tried, but was equally unintelligible to the majority, and the poor Slavonic enthusiasts, whose only common feeling was a common hatred against the Germans, were at last obliged to express themselves in the hated German language, as the only one that was generally understood! But just then another Slavonic Congress was assembling in Prague, in the shape of Galician lancers, Croatian and Slovak grenadiers, and Bohemian gunners and cuirassiers; and this real, armed Slavonic Congress, under the command of Windischgrätz, in less than twenty-four hours drove the founders of an imaginary Slavonian supremacy out of the town, and dispersed them to the winds.

The Bohemian, Moravian, Dalmatian, and part of the Polish deputies (the aristocracy) to the Austrian Constituent Diet, made in that Assembly a systematic war upon the German element. The Germans, and part of the Poles (the impoverished nobility), were in this Assembly the chief supporters of revolutionary progress; the mass of the Slavonic deputies, in opposing them, were not satisfied with thus showing clearly the reactionary tendencies of their entire movement, but they were degraded enough to tamper and conspire with the very same Austrian Government which had dispersed their meeting at Prague. They, too, were paid for this infamous conduct; after supporting the Government during the insurrection of October, 1848, an event which finally secured to them a majority in the Diet, this now almost exclusively Slavonic Diet was dispersed by Austrian soldiers, the same as the Prague Congress, and the Panslavists threatened with imprisonment if they should stir again. And they have only obtained

this, that Slavonic nationality is now being everywhere undermined by Austrian centralization, a result for which they may thank their own fanaticism and blindness.

If the frontiers of Hungary and Germany had admitted of any doubt, there would certainly have been another quarrel there. But, fortunately, there was no pretext, and the interests of both nations being intimately related, they struggled against the same enemies, *viz.*, the Austrian Government and the Panslavistic fanaticism. The good understanding was not for a moment disturbed. But the Italian Revolution entangled at least a part of Germany in an internecine war, and it must be stated here, as a proof how far the Metternichian system had succeeded in keeping back the development of the public mind, that during the first six months of 1848, the same men that had in Vienna mounted the barricades, went, full of enthusiasm, to join the army that fought against the Italian patriots. This deplorable confusion of ideas did not, however, last long.

Lastly, there was the war with Denmark about Schleswig and Holstein. These countries, unquestionably German by nationality, language and predilection, are also from military, naval and commercial grounds necessary to Germany. Their inhabitants have, for the last three years, struggled hard against Danish intrusion. The right of treaties, besides, was for them. The Revolution of March brought them into open collision with the Danes, and Germany supported them. But while in Poland, in Italy, in Bohemia, and later on, in Hungary, military operations were pushed with the utmost vigor, in this the only popular, the only, at least partially, revolutionary war, a system of resultless marches and counter-marches was adopted, and an interference of foreign diplomacy was submitted to, which led, after many an heroic engagement, to a most miserable end. The German Government betrayed, during the war, the Schleswig-Holstein revolutionary army on every occasion, and allowed it purposely to be cut up, when dispersed or divided, by the Danes. The German corps of volunteers were treated the same.

But while thus the German name earned nothing but hatred on every side, the German Constitutional and Liberal Governments rubbed their hands for joy. They had succeeded in crushing the Polish and the Bohemian movements. They had everywhere revived the old national animosities, which heretofore had prevented any common understanding and action between the German, the Pole, the Italian. They had accustomed the people

to scenes of civil war and repression by the military. The Prussian army had regained its confidence in Poland, the Austrian army in Prague; and while the superabundant patriotism (“*die Patriotische Ueberkraft*,” as Heine has it) of revolutionary but shortsighted youth was led in Schleswig and Lombardy, to be crushed by the grape-shot of the enemy, the regular army, the real instrument of action, both of Prussia and Austria, was placed in a position to regain public favor by victories over the foreigner. But we repeat: these armies, strengthened by the Liberals as a means of action against the more advanced party, no sooner had recovered their self-confidence and their discipline in some degree, than they turned themselves against the Liberals, and restored to power the men of the old system. When Radetzky, in his camp beyond the Adige, received the first orders from the “responsible ministers” at Vienna, he exclaimed: “Who are these ministers? They are not the Government of Austria! Austria is now nowhere but in my camp; I and my army, we are Austria; and when we shall have beaten the Italians we shall reconquer the Empire for the Emperor!” And old Radetzky was right — but the imbecile “responsible” ministers at Vienna heeded him not.

London, February, 1852.

X. THE PARIS RISING — THE FRANKFORT ASSEMBLY.

March 18th, 1852.

As early as the beginning of April, 1848, the revolutionary torrent had found itself stemmed all over the Continent of Europe by the league which those classes of society that had profited by the first victory immediately formed with the vanquished. In France, the petty trading class and the Republican faction of the bourgeoisie had combined with the Monarchist bourgeoisie against the proletarians; in Germany and Italy, the victorious bourgeoisie had eagerly courted the support of the feudal nobility, the official bureaucracy, and the army, against the mass of the people and the petty traders. Very soon the united Conservative and Counter-Revolutionary parties again regained the ascendant. In England, an untimely and ill-prepared popular demonstration (April 10th) turned out a complete and decisive defeat of the popular party. In France, two similar movements (16th April and 15th May) were equally defeated. In Italy, King Bomba regained his authority by a single stroke on the 15th May. In Germany, the different new bourgeois Governments and their respective constituent Assemblies consolidated themselves, and if the eventful 15th of May gave rise, in Vienna, to a popular victory, this was an event of merely secondary importance, and may be considered the last successful flash of popular energy. In Hungary the movement appeared to turn into the quiet channel of perfect legality, and the Polish movement, as we have seen in our last, was stifled in the bud by Prussian bayonets. But as yet nothing was decided as to the eventual turn which things would take, and every inch of ground lost by the Revolutionary parties in the different countries only tended to close their ranks more and more for the decisive action.

The decisive action drew near. It could be fought in France only; for France, as long as England took no part in the revolutionary strife, or as Germany remained divided, was, by its national independence, civilization, and centralization, the only country to impart the impulse of a mighty convulsion to the surrounding countries. Accordingly, when, on the 23rd of June, 1848, the bloody struggle began in Paris, when every succeeding telegraph or mail more clearly exposed the fact to the eyes of Europe, that

this struggle was carried on between the mass of the working people on the one hand, and all the other classes of the Parisian population, supported by the army, on the other; when the fighting went on for several days with an exasperation unequalled in the history of modern civil warfare, but without any apparent advantage for either side — then it became evident to every one that this was the great decisive battle which would, if the insurrection were victorious, deluge the whole continent with renewed revolutions, or, if it was suppressed, bring about an at least momentary restoration of counter-revolutionary rule.

The proletarians of Paris were defeated, decimated, crushed with such an effect that even now they have not yet recovered from the blow. And immediately, all over Europe, the new and old Conservatives and Counter-Revolutionists raised their heads with an effrontery that showed how well they understood the importance of the event. The Press was everywhere attacked, the rights of meeting and association were interfered with, every little event in every small provincial town was taken profit of to disarm the people to declare a state of siege, to drill the troops in the new manoeuvres and artifices that Cavaignac had taught them. Besides, for the first time since February, the invincibility of a popular insurrection in a large town had been proved to be a delusion; the honor of the armies had been restored; the troops hitherto always defeated in street battles of importance regained confidence in their efficiency even in this kind of struggle.

From this defeat of the *ouvriers* of Paris may be dated the first positive steps and definite plans of the old feudal bureaucratic party in Germany, to get rid even of their momentary allies, the middle classes, and to restore Germany to the state she was in before the events of March. The army again was the decisive power in the State, and the army belonged not to the middle classes but to themselves. Even in Prussia, where before 1848 a considerable leaning of part of the lower grades of officers towards a Constitutional Government had been observed, the disorder introduced into the army by the Revolution had brought back those reasoning young men to their allegiance; as soon as the private soldier took a few liberties with regard to the officers, the necessity of discipline and passive obedience became at once strikingly evident to them. The vanquished nobles and bureaucrats now began to see their way before them; the army, more united than ever, flushed with victory in minor insurrections and in foreign

warfare, jealous of the great success the French soldiers had just attained — this army had only to be kept in constant petty conflicts with the people, and the decisive moment once at hand, it could with one great blow crush the Revolutionists, and set aside the presumptions of the middle class Parliamentarians. And the proper moment for such a decisive blow arrived soon enough.

We pass over the sometimes curious, but mostly tedious, parliamentary proceedings and local struggles that occupied, in Germany, the different parties during the summer. Suffice it to say that the supporters of the middle class interest in spite of numerous parliamentary triumphs, not one of which led to any practical result, very generally felt that their position between the extreme parties became daily more untenable, and that, therefore, they were obliged now to seek the alliance of the reactionists, and the next day to court the favor of the more popular factions. This constant vacillation gave the finishing stroke to their character in public opinion, and according to the turn events were taking, the contempt into which they had sunk, profited for the movement principally to the bureaucrats and feudalists.

By the beginning of autumn the relative position of the different parties had become exasperated and critical enough to make a decisive battle inevitable. The first engagements in this war between the democratic and revolutionary masses and the army took place at Frankfort. Though a mere secondary engagement, it was the first advantage of any note the troops acquired over the insurrection, and had a great moral effect. The fancy Government established by the Frankfort National Assembly had been allowed by Prussia, for very obvious reasons, to conclude an armistice with Denmark, which not only surrendered to Danish vengeance the Germans of Schleswig, but which also entirely disclaimed the more or less revolutionary principles which were generally supposed in the Danish war. This armistice was, by a majority of two or three, rejected in the Frankfort Assembly. A sham ministerial crisis followed this vote, but three days later the Assembly reconsidered their vote, and were actually induced to cancel it and acknowledge the armistice. This disgraceful proceeding roused the indignation of the people. Barricades were erected, but already sufficient troops had been drawn to Frankfort, and after six hours' fighting, the insurrection was suppressed. Similar, but less important, movements connected with this event took place in other parts of Germany (Baden, Cologne), but were equally defeated.

This preliminary engagement gave to the Counter-Revolutionary party the one great advantage, that now the only Government which had entirely — at least in semblance — originated with popular election, the Imperial Government of Frankfort, as well as the National Assembly, was ruined in the eyes of the people. This Government and this Assembly had been obliged to appeal to the bayonets of the troops against the manifestation of the popular will. They were compromised, and what little regard they might have been hitherto enabled to claim, this repudiation of their origin, the dependency upon the anti-popular Governments and their troops, made both the Lieutenant of the Empire, his ministers and his deputies, henceforth to be complete nullities. We shall soon see how first Austria, then Prussia, and later on the smaller States too, treated with contempt every order, every request, every deputation they received from this body of impotent dreamers.

We now come to the great counter-stroke in Germany, of the French battle of June, to that event which was as decisive for Germany as the proletarian struggle of Paris had been for France; we mean the revolution and subsequent storming of Vienna, October, 1848. But the importance of this battle is such, and the explanation of the different circumstances that more immediately contributed to its issue will take up such a portion of *The Tribune's* columns, as to necessitate its being treated in a separate letter.

London, February, 1852.

XI. THE VIENNA INSURRECTION.

March 19th, 1852.

We now come to the decisive event which formed the counter-revolutionary part in Germany to the Parisian insurrection of June, and which, by a single blow, turned the scale in favor of the Counter-Revolutionary party, — the insurrection of October, 1848, in Vienna.

We have seen what the position of the different classes was, in Vienna, after the victory of 12th March. We have also seen how the movement of German-Austria was entangled with and impeded by the events in the non-German provinces of Austria. It only remains for us, then, briefly to survey the causes which led to this last and most formidable rising of German-Austria.

The high aristocracy and the stock-jobbing bourgeoisie, which had formed the principal non-official supports of the Metternichian Government, were enabled, even after the events of March, to maintain a predominating influence with the Government, not only by the Court, the army and the bureaucracy, but still more by the horror of “anarchy,” which rapidly spread among the middle classes. They very soon ventured a few feelers in the shape of a Press Law, a nondescript Aristocratic Constitution, and an Electoral Law based upon the old division of “estates.” The so-called Constitutional ministry, consisting of half Liberal, timid, incapable bureaucrats, on the 14th of May, even ventured a direct attack upon the revolutionary organizations of the masses by dissolving the Central Committee of Delegates of the National Guard and Academic Legion; a body formed for the express purpose of controlling the Government, and calling out against it, in case of need, the popular forces. But this act only provoked the insurrection of the 15th May, by which the Government was forced to acknowledge the Committee, to repeal the Constitution and the Electoral Law and to grant the power of framing a new Fundamental Law to a Constitutional Diet, elected by universal suffrage. All this was confirmed on the following day by an Imperial proclamation. But the reactionary party, which also had its representatives in the ministry, soon got their “Liberal” colleagues to undertake a new attack upon the popular conquests. The Academic Legion, the stronghold of the movement party, the centre of

continuous agitation, had, on this very account, become obnoxious to the more moderate burghers of Vienna; on the 26th a ministerial decree dissolved it. Perhaps this blow might have succeeded, if it had been carried out by a part of the National Guard only, but the Government, not trusting them either, brought the military forward, and at once the National Guard turned round, united with the Academic Legion, and thus frustrated the ministerial project.

In the meantime, however, the Emperor and his Court had, on the 16th of May, left Vienna, and fled to Innsbruck. Here surrounded by the bigoted Tyroleans, whose loyalty was roused again by the danger of an invasion of their country by the Sardo-Lombardian army, supported by the vicinity of Radetzky's troops, within shell-range of whom Innsbruck lay, here the Counter-Revolutionary party found an asylum, from whence, uncontrolled, unobserved and safe, it might rally its scattered forces, repair and spread again all over the country the network of its plots. Communications were reopened with Radetzky, with Jellachich, and with Windischgrätz, as well as with the reliable men in the administrative hierarchy of the different provinces; intrigues were set on foot with the Slavonic chiefs, and thus a real force at the disposal of the Counter-Revolutionary camarilla was formed, while the impotent ministers in Vienna were allowed to wear their short and feeble popularity out in continual bickerings with the revolutionary masses, and in the debates of the forthcoming Constituent Assembly. Thus the policy of leaving the movement of the capital to itself for a time; a policy which must have led to the omnipotence of the movement party in a centralized and homogeneous country like France, here in Austria, in a heterogeneous political conglomerate, was one of the safest means of reorganizing the strength of the reactionists.

In Vienna the middle class, persuaded that after three successive defeats, and in the face of a Constituent Assembly based upon universal suffrage, the Court was no longer an opponent to be dreaded, fell more and more into that weariness and apathy, and that eternal outcry for order and tranquillity, which has everywhere seized this class after violent commotions and consequent derangement of trade. The manufactures of the Austrian capital are almost exclusively limited to articles of luxury, for which, since the Revolution and the flight of the Court, there had necessarily been little demand. The shout for a return to a regular system of government, and for a return of the Court, both of which were expected to bring about a revival of

commercial prosperity — this shout became now general among the middle classes. The meeting of the Constituent Assembly in July was hailed with delight as the end of the revolutionary era; so was the return of the Court, which, after the victories of Radetzky in Italy, and after the advent of the reactionary ministry of Doblhoff, considered itself strong enough to brave the popular torrent, and which, at the same time, was wanted in Vienna in order to complete its intrigues with the Slavonic majority of the Diet. While the Constituent Diet discussed the laws on the emancipation of the peasantry from feudal bondage and forced labor for the nobility, the Court completed a master stroke. On the 19th of August the Emperor was made to review the National Guard; the Imperial family, the courtiers, the general officers, outbade each other in flatteries to the armed burghers, who were already intoxicated with pride at thus seeing themselves publicly acknowledged as one of the important bodies of the State; and immediately afterwards a decree, signed by Herr Schwarzer, the only popular minister in the Cabinet, was published, withdrawing the Government aid, given hitherto to the workmen out of employ. The trick succeeded; the working classes got up a demonstration; the middle class National Guards declared for the decree of their minister; they were launched upon the “Anarchists,” fell like tigers on the unarmed and unresisting workpeople, and massacred a great number of them on the 23rd of August. Thus the unity and strength of the revolutionary force was broken; the class-struggle between bourgeois and proletarian had come in Vienna, too, to a bloody outbreak, and the counter-revolutionary camarilla saw the day approaching on which it might strike its grand blow.

The Hungarian affairs very soon offered an opportunity to proclaim openly the principles upon which it intended to act. On the 5th of October an Imperial decree in the *Vienna Gazette* — a decree countersigned by none of the responsible ministers for Hungary — declared the Hungarian Diet dissolved, and named the Ban Jellachich, of Croatia, civil and military governor of that country — Jellachich, the leader of South Slavonian reaction, a man who was actually at war with the lawful authorities of Hungary. At the same time orders were given to the troops in Vienna to march out and form part of the army which was to enforce Jellachich's authority. This, however, was showing the cloven foot too openly; every man in Vienna felt that war upon Hungary was war upon the principle of constitutional government, which principle was in the very decree trampled

upon by the attempt of the emperor to make decrees with legal force, without the countersign of a responsible minister. The people, the Academic Legion, the National Guard of Vienna, on the 6th of October rose in mass, and resisted the departure of the troops; some grenadiers passed over to the people; a short struggle took place between the popular forces and the troops; the minister of war, Latour, was massacred by the people, and in the evening the latter were victors. In the meantime, Ban Jellachich, beaten at Stuhlweissenburg by Perczel, had taken refuge near Vienna on German-Austrian territory; the Viennese troops that were to march to his support now took up an ostensibly hostile and defensive position against him; and the emperor and court had again fled to Olmütz, on semi-Slavonic territory.

But at Olmütz the Court found itself in very different circumstances from what it had been at Innsbruck. It was now in a position to open immediately the campaign against the Revolution. It was surrounded by the Slavonian deputies of the Constituent, who flocked in masses to Olmütz, and by the Slavonian enthusiasts from all parts of the monarchy. The campaign, in their eyes, was to be a war of Slavonian restoration and of extermination, against the two intruders, upon what was considered Slavonian soil, against the German and the Magyar. Windischgrätz, the conqueror of Prague, now commander of the army that was concentrated around Vienna, became at once the hero of Slavonian nationality. And his army concentrated rapidly from all sides. From Bohemia, Moravia, Styria, Upper Austria, and Italy, marched regiment after regiment on routes that converged at Vienna, to join the troops of Jellachich and the ex-garrison of the capital. Above sixty thousand men were thus united towards the end of October, and soon they commenced hemming in the imperial city on all sides, until, on the 30th of October, they were far enough advanced to venture upon the decisive attack.

In Vienna, in the meantime, confusion and helplessness was prevalent. The middle class, as soon as the victory was gained, became again possessed of their old distrust against the “anarchic” working classes; the working men, mindful of the treatment they had received, six weeks before, at the hands of the armed tradesmen, and of the unsteady, wavering policy of the middle class at large, would not trust to them the defence of the city, and demanded arms and military organization for themselves. The Academic Legion, full of zeal for the struggle against imperial despotism, were entirely incapable of understanding the nature of the estrangement of

the two classes, or of otherwise comprehending the necessities of the situation. There was confusion in the public mind, confusion in the ruling councils. The remnant of the German Diet deputies, and a few Slavonians, acting the part of spies for their friends at Olmütz, besides a few of the more revolutionary Polish deputies, sat in permanency; but instead of taking part resolutely, they lost all their time in idle debates upon the possibility of resisting the imperial army without overstepping the bounds of constitutional conventionalities. The committee of safety, composed of deputies from almost all the popular bodies of Vienna, although resolved to resist, was yet dominated by a majority of burghers and petty tradesmen, who never allowed it to follow up any determined, energetic line of action. The council of the Academic Legion passed heroic resolutions, but was in no way able to take the lead. The working classes, distrusted, disarmed, disorganized, hardly emerging from the intellectual bondage of the old *régime*, hardly awaking, not to a knowledge, but to a mere instinct of their social position and proper political line of action, could only make themselves heard by loud demonstrations, and could not be expected to be up to the difficulties of the moment. But they were ready — as they ever were in Germany during the revolution — to fight to the last, as soon as they obtained arms.

That was the state of things in Vienna. Outside, the reorganized Austrian army flushed with the victories of Radetzky in Italy; sixty or seventy thousand men well armed, well organized, and if not well commanded at least possessing commanders. Inside, confusion, class division, disorganization; a national guard part of which was resolved not to fight at all, part irresolute, and only the smallest part ready to act; a proletarian mass, powerful by numbers but without leaders, without any political education, subject to panic as well as to fits of fury almost without cause, a prey to every false rumor spread about, quite ready to fight, but unarmed, at least in the beginning, and incompletely armed, and barely organized when at last they were led to battle; a helpless Diet, discussing theoretical quibbles while the roof over their heads was almost burning; a leading committee without impulse or energy. Everything was changed from the days of March and May, when, in the counter-revolutionary camp, all was confusion, and when the only organized force was that created by the revolution. There could hardly be a doubt about the issue of such a struggle,

and whatever doubt there might be, was settled by the events of the 30th and 31st of October, and 1st November.

London, March, 1852.

XII. THE STORMING OF VIENNA — THE BETRAYAL OF VIENNA.

April 9th, 1852.

When at last the concentrated army of Windischgrätz commenced the attack upon Vienna, the forces that could be brought forward in defence were exceedingly insufficient for the purpose. Of the National Guard only a portion was to be brought to the entrenchments. A Proletarian Guard, it is true, had at last been hastily formed, but owing to the lateness of the attempt to thus make available the most numerous, most daring, and most energetic part of the population, it was too little inured to the use of arms and to the very first rudiments of discipline to offer a successful resistance. Thus the Academic Legion, three to four thousand strong, well exercised and disciplined to a certain degree, brave and enthusiastic, was, militarily speaking, the only force which was in a state to do its work successfully. But what were they, together with the few reliable National Guards, and with the confused mass of the armed proletarians, in opposition to the far more numerous regulars of Windischgrätz, not counting even the brigand hordes of Jellachich, hordes that were, by the very nature of their habits, very useful in a war from house to house, from lane to lane? And what but a few old, outworn, ill-mounted, and ill-served pieces of ordnance had the insurgents to oppose to that numerous and well-appointed artillery, of which Windischgrätz made such an unscrupulous use?

The nearer the danger drew, the more grew the confusion in Vienna. The Diet, up to the last moment, could not collect sufficient energy to call in for aid the Hungarian army of Perczel, encamped a few leagues below the capital. The committee passed contradictory resolutions, they themselves being, like the popular armed masses, floated up and down with the alternately rising and receding tide of rumors and counter-rumors. There was only one thing upon which all agreed — to respect property; and this was done in a degree almost ludicrous for such times. As to the final arrangement of a plan of defence, very little was done. Bem, the only man present who could have saved Vienna, if any could then in Vienna, an almost unknown foreigner, a Slavonian by birth, gave up the task, overwhelmed as he was by universal distrust. Had he persevered, he might

have been lynched as a traitor. Messenhauser, the commander of the insurgent forces, more of a novel-writer than even of a subaltern officer, was totally inadequate to the task; and yet, after eight months of revolutionary struggles, the popular party had not produced or acquired a military man of more ability than he. Thus the contest began. The Viennese considering their utterly inadequate means of defence, considering their utter absence of military skill and organization in the ranks, offered a most heroic resistance. In many places the order given by Bem, when he was in command, "to defend that post to the last man," was carried out to the letter. But force prevailed. Barricade after barricade was swept away by the imperial artillery in the long and wide avenues which form the main streets of the suburbs; and on the evening of the second day's fighting the Croats occupied the range of houses facing the glacis of the Old Town. A feeble and disorderly attack of the Hungarian army had been utterly defeated; and during an armistice, while some parties in the Old Town capitulated, while others hesitated and spread confusion, while the remnants of the Academic Legion prepared fresh intrenchments, an entrance was made by the imperialists, and in the midst of the general disorder the Old Town was carried.

The immediate consequences of this victory, the brutalities and executions by martial law, the unheard-of cruelties and infamies committed by the Slavonian hordes let loose upon Vienna, are too well known to be detailed here. The ulterior consequences, the entirely new turn given to German affairs by the defeat of the revolution in Vienna, we shall have reason to notice hereafter. There remain two points to be considered in connection with the storming of Vienna. The people of that capital had two allies — the Hungarians and the German people. Where were they in the hour of trial?

We have seen that the Viennese, with all the generosity of a newly freed people, had risen for a cause which, though ultimately their own, was in the first instance, and above all, that of the Hungarians. Rather than suffer the Austrian troops to march upon Hungary, they would draw their first and most terrific onslaught upon themselves. And while they thus nobly came forward for the support of their allies, the Hungarians, successful against Jellachich, drove him upon Vienna, and by their victory strengthened the force that was to attack that town. Under these circumstances it was the clear duty of Hungary to support, without delay, and with all disposable

forces, not the Diet of Vienna, not the Committee of Safety or any other official body at Vienna, but the *Viennese* revolution. And if Hungary should even have forgotten that Vienna had fought the first battle of Hungary, she owed it to her own safety not to forget that Vienna was the only outpost of Hungarian independence, and that after the fall of Vienna nothing could meet the advance of the imperial troops against herself. Now, we know very well all the Hungarians can say and have said in defence of their inactivity during the blockade and storming of Vienna: the insufficient state of their own force, the refusal of the Diet or any other official body in Vienna to call them in, the necessity to keep on constitutional ground, and to avoid complications with the German central power. But the fact is, as to the insufficient state of the Hungarian army, that in the first days after the Viennese revolution and the arrival of Jellachich, nothing was wanted in the shape of regular troops, as the Austrian regulars were very far from being concentrated; and that a courageous, unrelenting following up of the first advantage over Jellachich, even with nothing but the *Land Sturm* that had fought at Stuhlweissenburg, would have sufficed to effect a junction with the Viennese, and to adjourn to that day six months every concentration of an Austrian army. In war, and particularly in revolutionary warfare, rapidity of action until some decided advantage is gained is the first rule, and we have no hesitation in saying that upon *merely military grounds*. Perczel ought not to have stopped until his junction with the Viennese was affected. There was certainly some risk, but who ever won a battle without risking something? And did the people of Vienna risk nothing when they drew upon themselves — they, a population of four hundred thousand — the forces that were to march to the conquest of twelve millions of Hungarians? The military fault committed by waiting until the Austrians had united, and by making the feeble demonstration at Schwechat which ended, as it deserved to do, in an inglorious defeat — this military fault certainly incurred more risks than a resolute march upon Vienna against the disbanded brigands of Jellachich would have done.

But, it is said, such an advance of the Hungarians, unless authorized by some official body, would have been a violation of the German territory, would have brought on complications with the central power at Frankfort, and would have been, above all, an abandonment of the legal and constitutional policy which formed the strength of the Hungarian cause. Why, the official bodies in Vienna were nonentities! Was it the Diet, was it

the popular committees, who had risen for Hungary, or was it the people of Vienna, and they alone, who had taken to the musket to stand the brunt of the first battle for Hungary's independence? It was not this nor that official body in Vienna which it was important to uphold; all these bodies might, and would have been, upset very soon in the progress of the revolutionary development; but it was the ascendancy of the revolutionary movement, the unbroken progress of popular action itself, which alone was in question, and which alone could save Hungary from invasion. What forms this revolutionary movement afterwards might take, was the business of the Viennese, not of the Hungarians, so long as Vienna and German Austria at large continued their allies against the common enemy. But the question is, whether in this stickling of the Hungarian government for some quasi-legal authorization, we are not to see the first clear symptom of that pretence to a rather doubtful legality of proceeding, which, if it did not save Hungary, at least told very well, at a later period, before the English middle class audiences.

As to the pretext of possible conflicts with the central power of Germany at Frankfort, it is quite futile. The Frankfort authorities were *de facto* upset by the victory of the counter-revolution at Vienna; they would have been equally upset had the revolution there found the support necessary to defeat its enemies. And lastly, the great argument that Hungary could not leave legal and constitutional ground, may do very well for British free-traders, but it will never be deemed sufficient in the eyes of history. Suppose the people of Vienna had stuck to "legal and constitutional means" on the 13th of March, and on the 6th of October, what then of the "legal and constitutional" movement, and of all the glorious battles which, for the first time, brought Hungary to the notice of the civilized world? The very legal and constitutional ground upon which it is asserted the Hungarians moved in 1848 and 1849 was conquered for them by the exceedingly illegal and unconstitutional rising of the people of Vienna on the 13th March. It is not to our purpose here to discuss the revolutionary history of Hungary, but it may be deemed proper if we observe that it is utterly useless to professedly use merely legal means of resistance against an enemy who scorns such scruples; and if we add, that had it not been for this eternal pretence of legality which Görgey seized upon and turned against the Government, the devotion of Görgey's army to its general, and the disgraceful catastrophe of Villagos, would have been impossible. And when, at last, to save their

honor, the Hungarians came across the Leitha, in the latter end of October, 1848, was not this quite as illegal as any immediate and resolute attack would have been?

We are known to harbor no unfriendly feeling toward Hungary. We stood by her during the struggles; we may be allowed to say that our paper, the *Neue Rheinische Zeitung*, has done more than any other to render the Hungarian cause popular in Germany, by explaining the nature of the struggle between the Magyar and Slavonian races, and by following up the Hungarian war in a series of articles which have had paid them the compliment of being plagiarized in almost every subsequent book upon the subject, the works of native Hungarians and “eyewitnesses” not excepted. We even now, in any future continental convulsion, consider Hungary as the necessary and natural ally of Germany. But we have been severe enough upon our own countrymen, to have a right to speak out upon our neighbors; and then we have here to record facts with historical impartiality, and we must say that in this particular instance, the generous bravery of the people of Vienna was not only far more noble, but also more far-sighted than the cautious circumspection of the Hungarian Government. And, as a German, we may further be allowed to say, that not for all the showy victories and glorious battles of the Hungarian campaign, would we exchange that spontaneous, single-handed rising, and heroic resistance of the people of Vienna, our countrymen, which gave Hungary the time to organize the army that could do such great things.

The second ally of Vienna was the German people. But they were everywhere engaged in the same struggle as the Viennese. Frankfort, Baden, Cologne, had just been defeated and disarmed. In Berlin and Breslau the people were at daggers-drawn with the army, and daily expected to come to blows. Thus it was in every local center of action. Everywhere questions were pending that could only be settled by the force of arms; and now it was that for the first time were severely felt the disastrous consequences of the continuation of the old dismemberment and decentralization of Germany. The different questions in every State, every province, every town, were fundamentally the same; but they were brought forward everywhere under different shapes and pretexts, and had everywhere attained different degrees of maturity. Thus it happened that while in every locality the decisive gravity of the events at Vienna was felt, yet nowhere could an important blow be struck with any hope of bringing

the Viennese succor, or making a diversion in their favor; and there remained nothing to aid them but the Parliament and Central Power of Frankfort; they were appealed to on all hands; but what did they do?

The Frankfort Parliament and the bastard child it had brought to light by incestuous intercourse with the old German Diet, the so-called Central Power, profited by the Viennese movement to show forth their utter nullity. This contemptible Assembly, as we have seen, had long since sacrificed its virginity, and young as it was, it was already turning grey-headed and experienced in all the artifices of painting and pseudo-diplomatic prostitution. Of the dreams and illusions of power, of German regeneration and unity, that in the beginning had pervaded it, nothing remained but a set of Teutonic clap-trap phraseology, that was repeated on every occasion, and a firm belief of each individual member in his own importance, as well as in the credulity of the public. The original naivety was discarded; the representatives of the German people had turned practical men, that is to say, they had made it out that the less they did, and the more they prated, the safer would be their position as the umpires of the fate of Germany. Not that they considered their proceedings superfluous; quite the contrary. But they had found out that all really great questions, being to them forbidden ground, had better be let alone, and there, like a set of Byzantine doctors of the Lower Empire, they discussed with an importance and assiduity worthy of the fate that at last overtook them, theoretical dogmas long ago settled in every part of the civilized world, or microscopical practical questions which never led to any practical result. Thus, the Assembly being a sort of Lancastrian School for the mutual instruction of members, and being, therefore, very important to themselves, they were persuaded it was doing even more than the German people had a right to expect, and looked upon everyone as a traitor to the country who had impudence to ask them to come to any result.

When the Viennese insurrection broke out, there was a host of interpellations, debates, motions, and amendments upon it, which, of course, led to nothing. The Central Power was to interfere. It sent two commissioners, Welcker, the ex-Liberal, and Mosle, to Vienna. The travels of Don Quixote and Sancho Panza form matter for an Odyssey in comparison with the heroic feats and wonderful adventures of those two knight-errants of German Unity. Not daring to go to Vienna, they were bullied by Windischgrätz, wondered at by the idiot Emperor, and

impudently hoaxed by the Minister Stadion. Their despatches and reports are perhaps the only portion of the Frankfort transactions that will retain a place in German literature; they are a perfect satirical romance, ready cut and dried, and an eternal monument of disgrace for the Frankfort Assembly and its Government.

The left side of the Assembly had also sent two commissioners to Vienna, in order to uphold its authority there — Froebel and Robert Blum. Blum, when danger drew near, judged rightly that here the great battle of the German Revolution was to be fought, and unhesitatingly resolved to stake his head on the issue. Froebel, on the contrary, was of opinion that it was his duty to preserve himself for the important duties of his post at Frankfort. Blum was considered one of the most eloquent men of the Frankfort Assembly; he certainly was the most popular. His eloquence would not have stood the test of any experienced Parliamentary Assembly; he was too fond of the shallow declamations of a German dissenting preacher, and his arguments wanted both philosophical acumen and acquaintance with practical matters of fact. In politics he belonged to “Moderate Democracy,” a rather indefinite sort of thing, cherished on account of this very want of definiteness in its principles. But with all this Robert Blum was by nature a thorough, though somewhat polished, plebeian, and in decisive moments his plebeian instinct and plebeian energy got the better of his indefiniteness, and, therefore, indecisive political persuasion and knowledge. In such moments he raised himself far above the usual standard of his capacities.

Thus, in Vienna, he saw at a glance that here, not in the midst of the would-be elegant debates of Frankfort, the fate of his country would have to be decided. He at once made up his mind, gave up all idea of retreat, took a command in the revolutionary force, and behaved with extraordinary coolness and decision. It was he who retarded for a considerable time the taking of the town, and covered one of its sides from attack by burning the Tabor Bridge over the Danube. Everybody knows how, after the storming, he was arrested, tried by court-martial, and shot. He died like a hero. And the Frankfort Assembly, horrorstruck as it was, yet took the bloody insult with a seeming good grace. A resolution was carried, which, by the softness and diplomatic decency of its language, was more an insult to the grave of the murdered martyr than a damning stain upon Austria. But it was not to be

expected that this contemptible Assembly should resent the assassination of one of its members, particularly of the leader of the Left.

London, March, 1852.

XIII. THE PRUSSIAN ASSEMBLY — THE NATIONAL ASSEMBLY.

April 17th, 1852.

On the 1st of November Vienna fell, and on the 9th of the same month the dissolution of the Constituent Assembly in Berlin showed how much this event had at once raised the spirit and the strength of the Counter-Revolutionary party all over Germany.

The events of the summer of 1848 in Prussia are soon told. The Constituent Assembly, or rather “the Assembly elected for the purpose of agreeing upon a Constitution with the Crown,” and its majority of representatives of the middle class interest, had long since forfeited all public esteem by lending itself to all the intrigues of the Court, from fear of the more energetic elements of the population. They had confirmed, or rather restored, the obnoxious privileges of feudalism, and thus betrayed the liberty and the interests of the peasantry. They had neither been able to draw up a Constitution, nor to amend in any way the general legislation. They had occupied themselves almost exclusively with nice theoretical distinctions, mere formalities, and questions of constitutional etiquette. The Assembly, in fact, was more a school of Parliamentary *savoir vivre* for its members, than a body in which the people could take any interest. The majorities were, besides, very nicely balanced, and almost always decided by the wavering centers whose oscillations from right to left, and *vice versa*, upset, first the ministry of Camphausen, then that of Auerswald and Hansemann. But while thus the Liberals, here as everywhere else, let the occasion slip out of their hands, the Court reorganized its elements of strength among the nobility, and the most uncultivated portion of the rural population, as well as in the army and the bureaucracy. After Hansemann’s downfall, a ministry of bureaucrats and military officers, all staunch reactionists, was formed, which, however, seemingly gave way to the demands of the Parliament; and the Assembly acting upon the commodious principle of “measures, not men,” were actually duped into applauding this ministry, while they, of course, had no eyes for the concentration and organization of Counter-Revolutionary forces, which that same ministry carried on pretty openly. At last, the signal being given by the fall of

Vienna, the King dismissed its ministers, and replaced them by “men of action,” under the leadership of the present premier, Manteuffel. Then the dreaming Assembly at once awoke to the danger; it passed a vote of no confidence in the Cabinet, which was at once replied to by a decree removing the Assembly from Berlin, where it might, in case of a conflict, count upon the support of the masses, to Brandenburg, a petty provincial town dependent entirely upon the Government. The Assembly, however, declared that it could not be adjourned, removed or dissolved, except with its own consent. In the meantime, General Wrangle entered Berlin at the head of some forty thousand troops. In a meeting of the municipal magistrates and the officers of the National Guard, it was resolved not to offer any resistance. And now, after the Assembly and its Constituents, the Liberal bourgeoisie, had allowed the combined reactionary party to occupy every important position, and to wrest from their hands almost every means of defence, began that grand comedy of “passive and legal resistance” which they intended to be a glorious imitation of the example of Hampden, and of the first efforts of the Americans in the War of Independence. Berlin was declared in a state of siege, and Berlin remained tranquil; the National Guard was dissolved by the Government, and its arms were delivered up with the greatest punctuality. The Assembly was hunted down during a fortnight, from one place of meeting to another, and everywhere dispersed by the military, and the members of the Assembly begged of the citizens to remain tranquil. At last the Government having declared the Assembly dissolved, it passed a resolution to declare the levying of taxes illegal, and then its members dispersed themselves over the country to organize the refusal of taxes. But they found that they had been woefully mistaken in the choice of their means. After a few agitated weeks, followed by severe measures of the Government against the Opposition, everyone gave up the idea of refusing the taxes in order to please a defunct Assembly that had not even had the courage to defend itself.

Whether it was in the beginning of November, 1848, already too late to try armed resistance, or whether a part of the army, on finding serious opposition, would have turned over to the side of the Assembly, and thus decided the matter in its favor, is a question which may never be solved. But in revolution as in war, it is always necessary to show a strong front, and he who attacks is in the advantage; and in revolution as in war, it is of the highest necessity to stake everything on the decisive moment, whatever

the odds may be. There is not a single successful revolution in history that does not prove the truth of these axioms. Now, for the Prussian Revolution, the decisive moment had come in November, 1848; the Assembly, at the head, officially, of the whole revolutionary interest, did neither show a strong front, for it receded at every advance of the enemy; much less did it attack, for it chose even not to defend itself; and when the decisive moment came, when Wrangle, at the head of forty thousand men, knocked at the gates of Berlin, instead of finding, as he and all his officers fully expected, every street studded with barricades, every window turned into a loophole, he found the gates open, and the streets obstructed only by peaceful Berliner burghers, enjoying the joke they had played upon him, by delivering themselves up, hands and feet tied, unto the astonished soldiers. It is true, the Assembly and the people, if they had resisted, might have been beaten; Berlin might have been bombarded, and many hundreds might have been killed, without preventing the ultimate victory of the Royalist party. But that was no reason why they should surrender their arms at once. A well-contested defeat is a fact of as much revolutionary importance as an easily-won victory. The defeats of Paris in June, 1848, and of Vienna in October, certainly did far more in revolutionizing the minds of the people of these two cities than the victories of February and March. The Assembly and the people of Berlin would, probably, have shared the fate of the two towns above-named; but they would have fallen gloriously, and would have left behind themselves, in the minds of the survivors, a wish of revenge which in revolutionary times is one of the highest incentives to energetic and passionate action. It is a matter of course that, in every struggle, he who takes up the gauntlet risks being beaten; but is that a reason why he should confess himself beaten, and submit to the yoke without drawing the sword?

In a revolution he who commands a decisive position and surrenders it, instead of forcing the enemy to try his hands at an assault, invariably deserves to be treated as a traitor.

The same decree of the King of Prussia which dissolved the Constituent Assembly also proclaimed a new Constitution, founded upon the draft which had been made by a Committee of that Assembly, but enlarging in some points the powers of the Crown, and rendering doubtful in others those of the Parliament. This Constitution established two Chambers, which were to meet soon for the purpose of confirming and revising it.

We need hardly ask where the German National Assembly was during the “legal and peaceful” struggle of the Prussian Constitutionalists. It was, as usual, at Frankfort, occupied with passing very tame resolutions against the proceedings of the Prussian Government, and admiring the “imposing spectacle of the passive, legal, and unanimous resistance of a whole people against brutal force.” The Central Government sent commissioners to Berlin to intercede between the Ministry and the Assembly; but they met the same fate as their predecessors at Olmütz, and were politely shown out. The Left of the National Assembly, *i.e.*, the so-called Radical party, sent also their commissioners; but after having duly convinced themselves of the utter helplessness of the Berlin Assembly, and confessed their own equal helplessness, they returned to Frankfort to report progress, and to testify to the admirably peaceful conduct of the population of Berlin. Nay, more; when Herr Bassermann, one of the Central Government’s commissioners, reported that the late stringent measures of the Prussian ministers were not without foundation, inasmuch as there had of late been seen loitering about the streets of Berlin sundry, savage-looking characters, such as always appear previous to anarchical movements (and which ever since have been named “Bassermannic characters”), these worthy deputies of the Left and energetic representatives of the revolutionary interest actually arose to make oath, and testify that such was not the case! Thus within two months the total impotency of the Frankfort Assembly was signally proved. There could be no more glaring proofs that this body was totally inadequate to its task; nay, that it had not even the remotest idea of what its task really was. The fact that both in Vienna and in Berlin the fate of the Revolution was settled, that in both these capitals the most important and vital questions were disposed of, without the existence of the Frankfort Assembly ever being taken the slightest notice of — this fact alone is sufficient to establish that the body in question was a mere debating-club, composed of a set of dupes, who allowed the Governments to use them as Parliamentary puppet, shown to amuse the shopkeepers and petty tradesmen of petty States and petty towns, as long as it was considered convenient to divert the attention of these parties. How long this was considered convenient we shall soon see. But it is a fact worthy of attention that among all the “eminent” men of this Assembly there was not one who had the slightest apprehension of the part they were made to perform, and that even up to the present day ex-

members of the Frankfort Club have invariably organs of historical perception quite peculiar to themselves.

London, March, 1852.

XIV. THE RESTORATION OF ORDER — DIET AND CHAMBER

April 24th, 1852.

The first months of the year 1849 were employed by the Austrian and Prussian Governments in following up the advantages obtained in October and November, 1848. The Austrian Diet, ever since the taking of Vienna, had carried on a merely nominal existence in a small Moravian country-town, named Kremsir. Here the Slavonian deputies, who, with their constituents, had been mainly instrumental in raising the Austrian Government from its prostration, were singularly punished for their treachery against the European Revolution. As soon as the Government had recovered its strength, it treated the Diet and its Slavonian majority with the utmost contempt, and when the first successes of the Imperial arms foreboded a speedy termination of the Hungarian War, the Diet, on the 4th of March, was dissolved, and the deputies dispersed by military force. Then at last the Slavonians saw that they were duped, and then they shouted: "Let us go to Frankfort and carry on there the opposition which we cannot pursue here!" But it was then too late, and the very fact that they had no other alternative than either to remain quiet or to join the impotent Frankfort Assembly, this fact alone was sufficient to show their utter helplessness.

Thus ended for the present, and most likely for ever, the attempts of the Slavonians of Germany to recover an independent national existence. Scattered remnants of numerous nations, whose nationality and political vitality had long been extinguished, and who in consequence had been obliged, for almost a thousand years, to follow in the wake of a mightier nation, their conqueror, the same as the Welsh in England, the Basques in Spain, the Bas-Bretons in France, and at a more recent period the Spanish and French Creoles in those portions of North America occupied of late by the Anglo-American race — these dying nationalities, the Bohemians, Carinthians, Dalmatians, etc., had tried to profit by the universal confusion of 1848, in order to restore their political *status quo* of A.D. 800. The history of a thousand years ought to have shown them that such a retrogression was impossible; that if all the territory east of the Elbe and Saale had at one time been occupied by kindred Slavonians, this fact merely

proved the historical tendency, and at the same time physical and intellectual power of the German nation to subdue, absorb, and assimilate its ancient eastern neighbors; that this tendency of absorption on the part of the Germans had always been, and still was, one of the mightiest means by which the civilization of Western Europe had been spread in the east of that continent; that it could only cease whenever the process of Germanization had reached the frontier of large, compact, unbroken nations, capable of an independent national life, such as the Hungarians, and in some degree the Poles; and that, therefore, the natural and inevitable fate of these dying nations was to allow this process of dissolution and absorption by their stronger neighbors to complete itself. Certainly this is no very flattering prospect for the national ambition of the Panslavistic dreamers who succeeded in agitating a portion of the Bohemian and South Slavonian people; but can they expect that history would retrograde a thousand years in order to please a few phthisical bodies of men, who in every part of the territory they occupy are interspersed with and surrounded by Germans, who from time almost immemorial have had for all purposes of civilization no other language but the German, and who lack the very first conditions of national existence, numbers and compactness of territory? Thus, the Panslavistic rising, which everywhere in the German and Hungarian Slavonic territories was the cloak for the restoration to independence of all these numberless petty nations, everywhere clashed with the European revolutionary movements, and the Slavonians, although pretending to fight for liberty, were invariably (the Democratic portion of the Poles excepted) found on the side of despotism and reaction. Thus it was in Germany, thus in Hungary, thus even here and there in Turkey. Traitors to the popular cause, supporters and chief props to the Austrian Government's cabal, they placed themselves in the position of outlaws in the eyes of all revolutionary nations. And although nowhere the mass of the people had a part in the petty squabbles about nationality raised by the Panslavistic leaders, for the very reason that they were too ignorant, yet it will never be forgotten that in Prague, in a half-German town, crowds of Slavonian fanatics cheered and repeated the cry: "Rather the Russian knout than German Liberty!" After their first evaporated effort in 1848, and after the lesson the Austrian Government gave them, it is not likely that another attempt at a later opportunity will be made. But if they should try again under similar pretexts to ally themselves to the counter-revolutionary force, the duty of Germany

is clear. No country in a state of revolution and involved in external war can tolerate a Vendée in its very heart.

As to the Constitution proclaimed by the Emperor at the same time with the dissolution of the Diet, there is no need to revert to it, as it never had a practical existence, and is now done away with altogether. Absolutism has been restored in Austria to all intents and purposes ever since the 4th March, 1849.

In Prussia, the Chambers met in February for the ratification and revision of the new Charter proclaimed by the King. They sat for about six weeks, humble and meek enough in their behavior toward the Government, yet not quite prepared to go the lengths the King and his ministers wished them to go. Therefore, as soon as a suitable occasion presented itself, they were dissolved.

Thus both Austria and Prussia had for the moment got rid of the shackles of parliamentary control. The Governments now concentrated all power in themselves, and could bring that power to bear wherever it was wanted: Austria upon Hungary and Italy, Prussia upon Germany. For Prussia, too, was preparing for a campaign by which "order" was to be restored in the smaller States.

Counter-revolution being now paramount in the two great centres of action in Germany, — in Vienna and Berlin, — there remained only the lesser States in which the struggle was still undecided, although the balance there, too, was leaning more and more against the revolutionary interest. These smaller States, we have said, found a common centre in the National Assembly at Frankfort. Now, this so-called National Assembly, although its reactionist spirit had long been evident, so much so that the very people of Frankfort had risen in arms against it, yet its origin was of more or less revolutionary nature; it occupied an abnormal, revolutionary position in January; its competence had never been defined, and it had at last come to the decision — which, however, was never recognized by the larger States — that its resolutions had the force of law. Under these circumstances, and when the Constitutionalist-Monarchial party saw their positions turned by the recovering Absolutists, it is not to be wondered that the Liberal, monarchical bourgeoisie of almost the whole of Germany should place their last hopes upon the majority of this Assembly, just as the petty shopkeepers in the rest, the nucleus of the Democratic party, gathered in their growing distress around the minority of that same body, which indeed formed the

last compact Parliamentary phalanx of Democracy. On the other hand, the larger Governments, and particularly the Prussian Ministry, saw more and more the incompatibility of such an irregular elective body with the restored monarchical system of Germany, and if they did not at once force its dissolution, it was only because the time had not yet come, and because Prussia hoped first to use it for the furthering of its own ambitious purposes.

In the meantime, that poor Assembly itself fell into a greater and greater confusion. Its deputations and commissaries had been treated with the utmost contempt, both in Vienna and Berlin; one of its members, in spite of his parliamentary inviolability, had been executed in Vienna as a common rebel. Its decrees were nowhere heeded; if they were noticed at all by the larger powers, it was merely by protesting notes which disputed the authority of the Assembly to pass laws and resolutions binding upon their Governments. The Representative of the Assembly, the Central Executive power, was involved in diplomatic squabbles with almost all the Cabinets of Germany, and, in spite of all their efforts, neither Assembly nor Central Government could bring Austria and Prussia to state their ultimate views, plans and demands. The Assembly, at last, commenced to see clearly, at least so far, that it had allowed all power to slip out of its hands, that it was at the mercy of Austria and Prussia, and that if it intended making a Federal Constitution for Germany at all, it must set about the thing at once and in good earnest. And many of the vacillating members also saw clearly that they had been egregiously duped by the Governments. But what were they, in their impotent position, able to do now? The only thing that could have saved them would have been promptly and decidedly to pass over into the popular camp; but the success, even of that step, was more than doubtful; and then, where in this helpless crowd of undecided, shortsighted, self-conceited beings, who, when the eternal noise of contradictory rumors and diplomatic notes completely stunned them, sought their only consolation and support in the everlastingly repeated assurance that they were the best, the greatest, the wisest men of the country, and that they alone could save Germany — where, we say, among these poor creatures, whom a single year of Parliamentary life had turned into complete idiots, where were the men for a prompt and decisive resolution, much less for energetic and consistent action?

At last the Austrian Government threw off the mask. In its Constitution of the 4th of March, it proclaimed Austria an indivisible monarchy, with

common finances, system of customs-duties, of military establishments, thereby effacing every barrier and distinction between the German and non-German provinces. This declaration was made in the face of resolutions and articles of the intended Federal Constitution which had been already passed by the Frankfort Assembly. It was the gauntlet of war thrown down to it by Austria, and the poor Assembly had no other choice but to take it up. This it did with a deal of blustering, which Austria, in the consciousness of her power, and of the utter nothingness of the Assembly, could well afford to allow to pass. And this precious representation, as it styled itself, of the German people, in order to revenge itself for this insult on the part of Austria, saw nothing better before it than to throw itself, hands and feet tied, at the feet of the Prussian Government. Incredible as it would seem, it bent its knees before the very ministers whom it had condemned as unconstitutional and anti-popular, and whose dismissal it had in vain insisted upon. The details of this disgraceful transaction, and the tragicomical events that followed, will form the subject of our next.

London, April, 1852.

XV. THE TRIUMPH OF PRUSSIA.

July 27th, 1852.

We now come to the last chapter in the history of the German Revolution; the conflict of the National Assembly with the Governments of the different States, especially of Prussia; the insurrection of Southern and Western Germany, and its final overthrow by Prussia.

We have already seen the Frankfort National Assembly at work. We have seen it kicked by Austria, insulted by Prussia, disobeyed by the lesser States, duped by its own impotent Central "Government," which again was the dupe of all and every prince in the country. But at last things began to look threatening for this weak, vacillating, insipid legislative body. It was forced to come to the conclusion that "the sublime idea of Germany unity was threatened in its realization," which meant neither more nor less than that the Frankfort Assembly, and all it had done, and was about to do, were very likely to end in smoke. Thus it set to work in good earnest in order to bring forth, as soon as possible, its grand production, the "Imperial Constitution." There was, however, one difficulty. What Executive Government was there to be? An Executive Council? No; that would have been, they thought in their wisdom, making Germany a Republic. A "president"? That would come to the same. Thus they must revive the old Imperial dignity. But — as, of course, a prince was to be emperor — who should it be? Certainly none of the *Dii minorum gentium*, from Reuss-Schleitz-Greiz-Lobenstein-Ebersdorf up to Bavaria; neither Austria nor Prussia would have borne that. It could only be Austria or Prussia. But which of the two? There is no doubt that, under otherwise favorable circumstances, this august Assembly would be sitting up to the present day, discussing this important dilemma without being able to come to a conclusion, if the Austrian Government had not cut the Gordian knot, and saved them the trouble.

Austria knew very well that from the moment in which she could again appear before Europe with all her provinces subdued, as a strong and great European power, the very law of political gravitation would draw the remainder of Germany into her orbit, without the help of any authority which an Imperial crown, conferred by the Frankfort Assembly, could give

her. Austria had been far stronger, far freer in her movements, since she shook off the powerless *crown* of the German Empire — a crown which clogged her own independent policy, while it added not one iota to her strength, either within or without Germany. And supposing the case that Austria could not maintain her footing in Italy and Hungary, why, then she was dissolved, annihilated in Germany too, and could never pretend to re seize a crown which had slipped from her hands while she was in the full possession of her strength. Thus Austria at once declared against all imperialist resurrections, and plainly demanded the restoration of the German Diet, the only Central Government of Germany known and recognized by the treaties of 1815; and on the 4th of March, 1849, issued that Constitution which had no other meaning than to declare Austria an indivisible, centralized, and independent monarchy, distinct even from that Germany which the Frankfort Assembly was to reorganize.

This open declaration of war left, indeed, the Frankfort wiseacres no other choice but to exclude Austria from Germany, and to create out of the remainder of that country a sort of lower empire, a “little Germany,” the rather shabby Imperial mantle of which was to fall on the shoulders of His Majesty of Prussia. This, it will be recollected, was the renewal of an old project fostered already some six or eight years ago by a party of South and Middle German Liberal *doctrinaires*, who considered as a godsend the degrading circumstances by which their old crotchet was now again brought forward as the latest “new move” for the salvation of the country.

They accordingly finished, in February and March, 1849, the debate on the Imperial Constitution, together with the Declaration of Rights and the Imperial Electoral Law; not, however, without being obliged to make, in a great many points, the most contradictory concessions — now to the Conservative or rather Reactionary party — now to the more advanced factions of the Assembly. In fact, it was evident that the leadership of the Assembly, which had formerly belonged to the Right and Right Centre (the Conservatives and Reactionists), was gradually, although slowly, passing toward the Left or Democratic side of that body. The rather dubious position of the Austrian deputies in an Assembly which had excluded their country from Germany, and in which they yet were called upon to sit and vote, favored the derangement of its equipoise; and thus, as early as the end of February, the Left Centre and Left found themselves, by the help of the Austrian votes, very generally in a majority, while on other days the

Conservative faction of the Austrians, all of a sudden, and for the fun of the thing, voting with the Right, threw the balance again on the other side. They intended, by these sudden *soubresauts*, to bring the Assembly into contempt, which, however, was quite unnecessary, the mass of the people being long since convinced of the utter hollowness and futility of anything coming from Frankfort. What a specimen of a Constitution, in the meantime, was framed under such jumping and counter-jumping, may easily be imagined.

The Left of the Assembly — this *élite* and pride of revolutionary Germany, as it believed itself to be — was entirely intoxicated with the few paltry successes it obtained by the good-will, or rather the ill-will, of a set of Austrian politicians, acting under the instigation and for the interest of Austrian despotism. Whenever the slightest approximation to their own not very well-defined principles had, in a hom[oe]opathically diluted shape, obtained a sort of sanction by the Frankfort Assembly, these Democrats proclaimed that they had saved the country and the people. These poor, weak-minded men, during the course of their generally very obscure lives, had been so little accustomed to anything like success, that they actually believed their paltry amendments, passed with two or three votes majority, would change the face of Europe. They had, from the beginning of their legislative career, been more imbued than any other faction of the Assembly with that incurable malady *Parliamentary crétinism*, a disorder which penetrates its unfortunate victims with the solemn conviction that the whole world, its history and future, are governed and determined by a majority of votes in that particular representative body which has the honor to count them among its members, and that all and everything going on outside the walls of their house — wars, revolutions, railway-constructing, colonizing of whole new continents, California gold discoveries, Central American canals, Russian armies, and whatever else may have some little claim to influence upon the destinies of mankind — is nothing compared with the incommensurable events hinging upon the important question, whatever it may be, just at that moment occupying the attention of their honorable house. Thus it was the Democratic party of the Assembly, by effectually smuggling a few of their nostrums into the “Imperial Constitution,” first became bound to support it, although in every essential point it flatly contradicted their own oft-proclaimed principles, and at last, when this mongrel work was abandoned, and bequeathed to them by its main authors,

accepted the inheritance, and held out for this *Monarchical* Constitution, even in opposition to everybody who *then* proclaimed their own *Republican* principles.

But it must be confessed that in this the contradiction was merely apparent. The indeterminate, self-contradictory, immature character of the Imperial Constitution was the very image of the immature, confused, conflicting political ideas of these Democratic gentlemen. And if their own sayings and writings — as far as they could write — were not sufficient proof of this, their actions would furnish such proof; for among sensible people it is a matter of course to judge of a man, not by his professions, but his actions; not by what he pretends to be, but by what he does, and what he really is; and the deeds of these heroes of German Democracy speak loud enough for themselves, as we shall learn by and by. However, the Imperial Constitution, with all its appendages and paraphernalia, was definitely passed, and on the 28th of March, the King of Prussia was, by 290 votes against 248 who abstained, and 200 who were absent, elected Emperor of Germany *minus Austria*. The historical irony was complete; the Imperial farce executed in the streets of astonished Berlin, three days after the Revolution of March 18th, 1848, by Frederick William IV., while in a state which elsewhere would come under the Maine Liquor Law — this disgusting farce, just one year afterwards, had been sanctioned by the pretended Representative Assembly of all Germany. That, then, was the result of the German Revolution!

London, July, 1852.

XVI. THE ASSEMBLY AND THE GOVERNMENTS.

August 19th, 1852.

The National Assembly of Frankfort, after having elected the King of Prussia Emperor of Germany (*minus* Austria), sent a deputation to Berlin to offer him the crown, and then adjourned. On the 3rd of April, Frederick William received the deputies. He told them that, although he accepted the right of precedence over all the other princes of Germany, which this vote of the people's representatives had given him, yet he could not accept the Imperial crown as long as he was not sure that the remaining princes acknowledged his supremacy, and the Imperial Constitution conferring those rights upon him. It would be, he added, for the Governments of Germany to see whether this Constitution was such as could be ratified by them. At all events, Emperor or not, he always would be found ready, he concluded, to draw the sword against either the external or the internal foe. We shall see how he kept his promise in a manner rather startling for the National Assembly.

The Frankfort wiseacres, after profound diplomatic inquiry, at last came to the conclusion that this answer amounted to a refusal of the crown. They then (April 12th) resolved: That the Imperial Constitution was the law of the land, and must be maintained; and not seeing their way at all before them, elected a Committee of thirty, to make proposals as to the means how this Constitution could be carried out.

This resolution was the signal for the conflict between the Frankfort Assembly and the German Governments which now broke out. The middle classes, and especially the smaller trading class, had all at once declared for the new Frankfort Constitution. They could not wait any longer the moment which was "to close the Revolution." In Austria and Prussia the Revolution had, for the moment, been closed by the interference of the armed power. The classes in question would have preferred a less forcible mode of performing that operation, but they had not had a chance; the thing was done, and they had to make the best of it, a resolution which they at once took and carried out most heroically. In the smaller States, where things had been going on comparatively smoothly, the middle classes had long since

been thrown back into that showy, but resultless, because powerless, parliamentary agitation, which was most congenial to themselves. The different States of Germany, as regarded each of them separately, appeared thus to have attained that new and definite form which was supposed to enable them to enter henceforth the path of peaceful constitutional development. There only remained one open question, that of the new political organization of the German Confederacy. And this question, the only one which still appeared fraught with danger, it was considered a necessity to resolve at once. Hence the pressure exerted upon the Frankfort Assembly by the middle classes, in order to induce it to get the Constitution ready as soon as possible; hence the resolution among the higher and lower bourgeoisie to accept and support this Constitution, whatever it might be, in order to create a settled state of things without delay. Thus from the very beginning the agitation for the Imperial Constitution arose out of a reactionary feeling, and sprang up among these classes which were long since tired of the Revolution.

But there was another feature in it. The first and fundamental principles of the future German Constitution had been voted during the first months of spring and summer, 1848, a time when popular agitation was still rife. The resolutions then passed, though completely reactionary *then*, now, after the arbitrary acts of the Austrian and Prussian Governments, appeared exceedingly Liberal, and even Democratic. The standard of comparison had changed. The Frankfort Assembly could not, without moral suicide, strike out these once-voted provisions, and model the Imperial Constitution upon those which the Austrian and Prussian Governments had dictated, sword in hand. Besides, as we have seen, the majority in that Assembly had changed sides, and the Liberal and Democratic party were rising in influence. Thus the Imperial Constitution not only was distinguished by its apparently exclusive popular origin, but at the same time, full of contradiction as it was, it yet was the most Liberal Constitution in all Germany. Its greatest fault was, that it was a mere sheet of paper, with no power to back its provisions.

Under these circumstances it was natural that the so-called Democratic party, that is, the mass of the petty trading class, should cling to the Imperial Constitution. This class had always been more forward in its demands than the Liberal-Monarchico-Constitutional bourgeoisie; it had shown a bolder front, it had very often threatened armed resistance, it was lavish in its

promises to sacrifice its blood and its existence in the struggle for freedom; but it had already given plenty of proofs that on the day of danger it was nowhere, and that it never felt more comfortable than the day after a decisive defeat, when everything being lost, it had at least the consolation to know that somehow or other the matter *was* settled. While, therefore, the adhesion of the large bankers, manufacturers, and merchants was of a more reserved character, more like a simple demonstration in favor of the Frankfort Constitution, the class just beneath them, our valiant Democratic shopkeepers, came forward in grand style, and, as usual, proclaimed they would rather spill their last drop of blood than let the Imperial Constitution fall to the ground.

Supported by these two parties, the bourgeois adherents of the Constitutional Royalty, and the more or less Democratic shopkeepers, the agitation for the immediate establishment of the Imperial Constitution gained ground rapidly, and found its most powerful expression in the Parliaments of the several States. The Chambers of Prussia, of Hanover, of Saxony, of Baden, of Württemberg, declared in its favor. The struggle between the Governments and the Frankfort Assembly assumed a threatening aspect.

The Governments, however, acted rapidly. The Prussian Chambers were dissolved, anti-constitutionally, as they had to revise and confirm the Constitution; riots broke out at Berlin, provoked intentionally by the Government, and the next day, the 28th of April, the Prussian Ministry issued a circular note, in which the Imperial Constitution was held up as a most anarchical and revolutionary document, which it was for the Governments of Germany to remodel and purify. Thus Prussia denied, point-blank, that sovereign constituent power which the wise men at Frankfort had always boasted of, but never established. Thus a Congress of Princes, a renewal of the old Federal Diet, was called upon to sit in judgment on that Constitution which had already been promulgated as law. And at the same time Prussia concentrated troops at Kreuznach, three days' march from Frankfort, and called upon the smaller States to follow its example, by also dissolving their Chambers as soon as they should give their adhesion to the Frankfort Assembly. This example was speedily followed by Hanover and Saxony.

It was evident that a decision of the struggle by force of arms could not be avoided. The hostility of the Governments, the agitation among the

people, were daily showing themselves in stronger colors. The military were everywhere worked upon by the Democratic citizens, and in the south of Germany with great success. Large mass meetings were everywhere held, passing resolutions to support the Imperial Constitution and the National Assembly, if need should be, with force of arms. At Cologne, a meeting of deputies of all the municipal councils of Rhenish Prussia took place for the same purpose. In the Palatinate, at Bergen, Fulda, Nuremberg, in the Odenwald, the peasantry met by myriads and worked themselves up into enthusiasm. At the same time the Constituent Assembly of France dissolved, and the new elections were prepared amid violent agitation, while on the eastern frontier of Germany, the Hungarians had within a month, by a succession of brilliant victories, rolled back the tide of Austrian invasion from the Theiss to the Leitha, and were every day expected to take Vienna by storm. Thus, popular imagination being on all hands worked up to the highest pitch, and the aggressive policy of the Governments defining itself more clearly every day, a violent collision could not be avoided, and cowardly imbecility only could persuade itself that the struggle was to come off peaceably. But this cowardly imbecility was most extensively represented in the Frankfort Assembly.

London, July, 1852.

XVII. INSURRECTION.

September 18, 1852.

The inevitable conflict between the National Assembly of Frankfort and the States Governments of Germany at last broke out in open hostilities during the first days of May, 1849. The Austrian deputies, recalled by their Government, had already left the Assembly and returned home, with the exception of a few members of the Left or Democratic party. The great body of the Conservative members, aware of the turn things were about to take, withdrew even before they were called upon to do so by their respective Governments. Thus, even independently of the causes which in the foregoing letters have been shown to strengthen the influence of the Left, the mere desertion of their posts by the members of the Right, sufficed to turn the old minority into a majority of the Assembly. The new majority, which, at no former time, had dreamed of ever obtaining that good fortune, had profited by their places on the opposition benches to spout against the weakness, the indecision, the indolence of the old majority, and of its Imperial Lieutenancy. Now all at once, *they* were called on to replace that old majority. *They* were now to show what they could perform. Of course, *their* career was to be one of energy, determination, activity. *They*, the *élite* of Germany, would soon be able to drive onwards the senile Lieutenant of the Empire, and his vacillating ministers, and in case that was impossible they would — there could be no doubt about it — by force of the sovereign right of the people, depose that impotent Government, and replace it by an energetic, indefatigable Executive, who would assure the salvation of Germany. Poor fellows! *Their* rule — if rule it can be named, where no one obeyed — was a still more ridiculous affair than even the rule of their predecessors.

The new majority declared that, in spite of all obstacles, the Imperial Constitution must be carried out, and *at once*; that on the 15th of July ensuing, the people were to elect the deputies of the new House of Representatives, and that this House was to meet at Frankfort on the 15th of August following. Now, this was an open declaration of war against those Governments that had not recognized the Imperial Constitution, the foremost among which were Prussia, Austria, Bavaria, comprising more

than three-fourths of the German population; a declaration of war which was speedily accepted by them. Prussia and Bavaria, too, recalled the deputies sent from their territories to Frankfort, and hastened their military preparations against the National Assembly, while, on the other hand, the demonstrations of the Democratic party (out of Parliament) in favor of the Imperial Constitution and of the National Assembly, acquired a more turbulent and violent character, and the mass of the working people, led by the men of the most extreme party, were ready to take up arms in a cause which, if it was not their own, at least gave them a chance of somewhat approaching their aims by clearing Germany of its old monarchical encumbrances. Thus everywhere the people and the Governments were at daggers drawn upon this subject; the outbreak was inevitable; the mine was charged, and it only wanted a spark to make it explode. The dissolution of the Chambers in Saxony, the calling in of the Landwehr (military reserve) in Prussia, the open resistance of the Government to the Imperial Constitution, were such sparks; they fell, and all at once the country was in a blaze. In Dresden, on the 4th of May, the people victoriously took possession of the town, and drove out the King, while all the surrounding districts sent re-inforcements to the insurgents. In Rhenish Prussia and Westphalia the Landwehr refused to march, took possession of the arsenals, and armed itself in defence of the Imperial Constitution. In the Palatinate the people seized the Bavarian Government officials, and the public moneys, and instituted a Committee of Defence, which placed the province under the protection of the National Assembly. In Würtemberg the people forced the King to acknowledge the Imperial Constitution, and in Baden the army, united with the people, forced the Grand Duke to flight, and erected a Provincial Government. In other parts of Germany the people only awaited a decisive signal from the National Assembly to rise in arms and place themselves at its disposal.

The position of the National Assembly was far more favorable than could have been expected after its ignoble career. The western half of Germany had taken up arms in its behalf; the military everywhere were vacillating; in the lesser States they were undoubtedly favorable to the movement. Austria was prostrated by the victorious advance of the Hungarians, and Russia, that reserve force of the German Governments, was straining all its powers in order to support Austria against the Magyar armies. There was only Prussia to subdue, and with the revolutionary

sympathies existing in that country, a chance certainly existed of attaining that end. Everything then depended upon the conduct of the Assembly.

Now, insurrection is an art quite as much as war or any other, and subject to certain rules of proceeding, which, when neglected, will produce the ruin of the party neglecting them. Those rules, logical deductions from the nature of the parties and the circumstances one has to deal with in such a case, are so plain and simple that the short experience of 1848 had made the Germans pretty well acquainted with them. Firstly, never play with insurrection unless you are fully prepared to face the consequences of your play. Insurrection is a calculus with very indefinite magnitudes, the value of which may change every day; the forces opposed to you have all the advantage of organization, discipline, and habitual authority: unless you bring strong odds against them you are defeated and ruined. Secondly, the insurrectionary career once entered upon, act with the greatest determination, and on the offensive. The defensive is the death of every armed rising; it is lost before it measures itself with its enemies. Surprise your antagonists while their forces are scattering, prepare new successes, however small, but daily; keep up the moral ascendancy which the first successful rising has given to you; rally those vacillating elements to your side which always follow the strongest impulse, and which always look out for the safer side; force your enemies to a retreat before they can collect their strength against you; in the words of Danton, the greatest master of revolutionary policy yet known, *de l'audace, de l'audace, encore de l'audace!*

What, then, was the National Assembly of Frankfort to do if it would escape the certain ruin which it was threatened with? First of all, to see clearly through the situation, and to convince itself that there was now no other choice than either to submit to the Governments unconditionally, or take up the cause of the armed insurrection without reserve or hesitation. Secondly, to publicly recognize all the insurrections that had already broken out, and to call the people to take up arms everywhere in defence of the national representation, outlawing all princes, ministers and others who should dare to oppose the sovereign people represented by its mandatories. Thirdly, to at once depose the German Imperial Lieutenant, to create a strong, active, unscrupulous Executive, to call insurgent troops to Frankfort for its immediate protection, thus offering at the same time a legal pretext for the spread of the insurrection, to organize into a compact body all the

forces at its disposal, and, in short, to profit quickly and unhesitatingly by every available means for strengthening its position and impairing that of its opponents.

Of all this the virtuous Democrats in the Frankfort Assembly did just the contrary. Not content with letting things take the course they liked, these worthies went so far as to suppress by their opposition all insurrectionary movements which were preparing. Thus, for instance, did Herr Karl Vogt at Nuremberg. They allowed the insurrections of Saxony, of Rhenish Prussia, of Westphalia to be suppressed without any other help than a posthumous, sentimental protest against the unfeeling violence of the Prussian Government. They kept up an underhand diplomatic intercourse with the South German insurrections but never gave them the support of their open acknowledgment. They knew that the Lieutenant of the Empire sided with the Governments, and yet they called upon *him*, who never stirred, to oppose the intrigues of these Governments. The ministers of the Empire, old Conservatives, ridiculed this impotent Assembly in every sitting, and they suffered it. And when William Wolff, a Silesian deputy, and one of the editors of the *New Rhenish Gazette*, called upon them to outlaw the Lieutenant of the Empire — who was, he justly said, nothing but the first and greatest traitor to the Empire, he was hooted down by the unanimous and virtuous indignation of those Democratic Revolutionists! In short, they went on talking, protesting, proclaiming, pronouncing, but never had the courage or the sense to act; while the hostile troops of the Governments drew nearer and nearer, and their own Executive, the Lieutenant of the Empire, was busily plotting with the German princes their speedy destruction. Thus even the last vestige of consideration was lost to this contemptible Assembly; the insurgents who had risen to defend it ceased to care any more for it, and when at last it came to a shameful end, as we shall see, it died without anybody taking any notice of its unhonored exit.

London, August, 1852.

XVIII. PETTY TRADERS.

October 2, 1852.

In our last we showed that the struggle between the German Governments on the one side, and the Frankfort Parliament on the other, had ultimately acquired such a degree of violence that in the first days of May, a great portion of Germany broke out in open insurrection; first Dresden, then the Bavarian Palatinate, parts of Rhenish Prussia, and at last Baden.

In all cases, the *real fighting* body of the insurgents, that body which first took up arms and gave battle to the troops consisted of the *working classes of the towns*. A portion of the poorer country population, laborers and petty farmers, generally joined them after the outbreak of the conflict. The greater number of the young men of all classes, below the capitalist class, were to be found, for a time at least, in the ranks of the insurgent armies, but this rather indiscriminate aggregate of young men very soon thinned as the aspect of affairs took a somewhat serious turn. The students particularly, those “representatives of intellect,” as they liked to call themselves, were the first to quit their standards, unless they were retained by the bestowal of officer’s rank, for which they, of course, had very seldom any qualifications.

The working class entered upon this insurrection as they would have done upon any other which promised either to remove some obstacles in their progress towards political dominion and social revolution, or, at least, to tie the more influential but less courageous classes of society to a more decided and revolutionary course than they had followed hitherto. The working class took up arms with a full knowledge that this was, in the direct bearings of the case, no quarrel of its own; but it followed up its only true policy, to allow no class that has risen on its shoulders (as the bourgeoisie had done in 1848) to fortify its class-government, without opening, at least, a fair field to the working classes for the struggle for its own interests, and, in any case, to bring matters to a crisis, by which either the nation was fairly and irresistibly launched in the revolutionary career, or else the *status quo* before the Revolution restored as nearly as possible, and, thereby, a new revolution rendered unavoidable. In both cases the working classes

represented the real and well-understood interest of the nation at large, in hastening as much as possible that revolutionary course which for the old societies of civilized Europe has now become a historical necessity, before any of them can again aspire to a more quiet and regular development of their resources.

As to country people that joined the insurrection, they were principally thrown into the arms of the Revolutionary party, partly by the relatively enormous load of taxation, and partly of feudal burdens pressing upon them.

Without any initiative of their own, they formed the tail of the other classes engaged in the insurrection, wavering between the working men on the one side, and the petty trading class on the other. Their own private social position, in almost every case, decided which way they turned; the agricultural laborer generally supported the city artisan; the small farmer was apt to go hand in hand with the small shopkeeper.

This class of petty tradesmen, the great importance and influence of which we have already several times adverted to, may be considered as the leading class of the insurrection of May, 1849. There being, this time, none of the large towns of Germany among the center of the movement, the petty trading class, which in middling and lesser towns always predominates, found the means of getting the direction of the movement into its hands. We have, moreover, seen that, in this struggle for the Imperial Constitution, and for the rights of the German Parliament, there were the interests of this peculiar class at stake. The Provisional Governments formed in all the insurgent districts represented in the majority of each of them this section of the people, and the length they went to may therefore be fairly taken as the measure of what the German petty bourgeoisie is capable of — capable, as we shall see, of nothing but ruining any movement that entrusts itself to its hands.

The petty bourgeoisie, great in boasting, is very impotent for action, and very shy in risking anything. The *mesquin* character of its commercial transactions and its credit operations is eminently apt to stamp its character with a want of energy and enterprise; it is, then, to be expected that similar qualities will mark its political career. Accordingly the petty bourgeoisie encouraged insurrection by big words, and great boasting as to what it was going to do; it was eager to seize upon power as soon as the insurrection, much against its will, had broken out; it used this power to no other purpose

but to destroy the effects of the insurrection. Wherever an armed conflict had brought matters to a serious crisis, there the shopkeepers stood aghast at the dangerous situation created for them; aghast at the people who had taken their boasting appeals to arms in earnest; aghast at the power thus thrust into their own hands; aghast, above all, at the consequences for themselves, for their social positions, for their fortunes, of the policy in which they were forced to engage themselves. Were they not expected to risk "life and property," as they used to say, for the cause of the insurrection? Were they not forced to take official positions in the insurrection, whereby, in the case of defeat, they risked the loss of their capital? And in case of victory, were they not sure to be immediately turned out of office, and to see their entire policy subverted by the victorious proletarians who formed the main body of their fighting army? Thus placed between opposing dangers which surrounded them on every side, the petty bourgeoisie knew not to turn its power to any other account than to let everything take its chance, whereby, of course, there was lost what little chance of success there might have been, and thus to ruin the insurrection altogether. Its policy, or rather want of policy, everywhere was the same, and, therefore, the insurrections of May, 1849, in all parts of Germany, are all cut out to the same pattern.

In Dresden, the struggle was kept on for four days in the streets of the town. The shopkeepers of Dresden, the "communal guard," not only did not fight, but in many instances favored the proceedings of the troops against the insurgents. These again consisted almost exclusively of working men from the surrounding manufacturing districts. They found an able and cool-headed commander in the Russian refugee Michael Bakunin, who afterwards was taken prisoner, and now is confined in the dungeons of Munkacs, Hungary. The intervention of numerous Prussian troops crushed this insurrection.

In Rhenish Prussia the actual fighting was of little importance. All the large towns being fortresses commanded by citadels, there could be only skirmishing on the part of the insurgents. As soon as a sufficient number of troops had been drawn together, there was an end to armed opposition.

In the Palatinate and Baden, on the contrary, a rich, fruitful province and an entire state fell into the hands of the insurrection. Money, arms, soldiers, warlike stores, everything was ready for use. The soldiers of the regular army themselves joined the insurgents; nay, in Baden, they were amongst

the foremost of them. The insurrections in Saxony and Rhenish Prussia sacrificed themselves in order to gain time for the organization of the South German movement. Never was there such a favorable position for a provincial and partial insurrection as this. A revolution was expected in Paris; the Hungarians were at the gates of Vienna; in all the central States of Germany, not only the people, but even the troops, were strongly in favor of the insurrection, and only wanted an opportunity to join it openly. And yet the movement, having once got into the hands of the petty bourgeoisie, was ruined from its very beginning. The petty bourgeois rulers, particularly of Baden — Herr Brentano at the head of them — never forgot that by usurping the place and prerogatives of the “lawful” sovereign, the Grand Duke, they were committing high treason. They sat down in their ministerial armchairs with the consciousness of criminality in their hearts. What can you expect of such cowards? They not only abandoned the insurrection to its own uncentralized, and therefore ineffective, spontaneity, they actually did everything in their power to take the sting out of the movement, to unman, to destroy it. And they succeeded, thanks to the zealous support of that deep class of politicians, the “Democratic” heroes of the petty bourgeoisie, who actually thought they were “saving the country,” while they allowed themselves to be led by their noses by a few men of a sharper cast, such as Brentano.

As to the fighting part of the business, never were military operations carried on in a more slovenly, more stolid way than under the Baden General-in-Chief Sigel, an ex-lieutenant of the regular army. Everything was got into confusion, every good opportunity was lost, every precious moment was loitered away with planning colossal, but impracticable projects, until, when at last the talented Pole Mieroslawski, took up the command, the army was disorganized, beaten, dispirited, badly provided for, opposed to an enemy four times more numerous, and withal, he could do nothing more than fight, at Waghäusel, a glorious though unsuccessful battle, carry out a clever retreat, offer a last hopeless fight under the walls of Rastatt, and resign. As in every insurrectionary war where armies are mixed of well-drilled soldiers and raw levies, there was plenty of heroism, and plenty of unsoldierlike, often unconceivable panic, in the revolutionary army; but, imperfect as it could not but be, it had at least the satisfaction that four times its number were not considered sufficient to put it to the rout, and that a hundred thousand regular troops, in a campaign against

twenty thousand insurgents, treated them, militarily, with as much respect as if they had to fight the Old Guard of Napoleon.

In May the insurrection had broken out; by the middle of July, 1849, it was entirely subdued and the first German Revolution was closed.

London. (Undated.)

XIX. THE CLOSE OF THE INSURRECTION.

October 23, 1852.

While the south and west of Germany was in open insurrection, and while it took the Governments from the first opening of hostilities at Dresden to the capitulation of Rastatt, rather more than ten weeks, to stifle this final blazing up of the first German Revolution, the National Assembly disappeared from the political theater without any notice being taken of its exit.

We left this august body at Frankfort, perplexed by the insolent attacks of the Governments upon its dignity, by the impotency and treacherous listlessness of the Central Power it had itself created, by the risings of the petty trading class for its defence, and of the working class for a more revolutionary ultimate end. Desolation and despair reigned supreme among its members; events had at once assumed such a definite and decisive shape that in a few days the illusions of these learned legislators as to their real power and influence were entirely broken down. The Conservatives, at the signal given by the Governments, had already retired from a body which, henceforth, could not exist any longer, except in defiance of the constituted authorities. The Liberals gave the matter up in utter discomfiture; they, too, threw up their commissions as representatives. Honorable gentlemen decamped by hundreds. From eight or nine hundred members the number had dwindled down so rapidly that now one hundred and fifty, and a few days after one hundred, were declared a quorum. And even these were difficult to muster, although the whole of the Democratic party remained.

The course to be followed by the remnants of a parliament was plain enough. They had only to take their stand openly and decidedly with the insurrection, to give it, thereby, whatever strength legality could confer upon it, while they themselves at once acquired an army for their own defence. They had to summon the Central Power to stop all hostilities at once; and if, as could be foreseen, this power neither could nor would do so, to depose it at once and put another more energetic Government in its place. If insurgent troops could not be brought to Frankfort (which, in the beginning, when the State Governments were little prepared and still hesitating, might have been easily done), then the Assembly could have

adjourned at once to the very center of the insurgent district. All this done at once, and resolutely, not later than the middle or end of May, might have opened chances both for the insurrection and for the National Assembly.

But such a determined course was not to be expected from the representatives of German shopocracy. These aspiring statesmen were not at all freed from their illusions. Those members who had lost their fatal belief in the strength and inviolability of the Parliament had already taken to their heels; the Democrats who remained, were not so easily induced to give up dreams of power and greatness which they had cherished for a twelvemonth. True to the course they had hitherto pursued, they shrank back from decisive action until every chance of success, nay, every chance to succumb, with at least the honors of war, had passed away. In order, then, to develop a fictitious, busy-body sort of activity, the sheer impotency of which, coupled with its high pretension, could not but excite pity and ridicule, they continued insinuating resolutions, addresses, and requests to an Imperial Lieutenant, who not even noticed them; to ministers who were in open league with the enemy. And when at last William Wolff, member for Striegan, one of the editors of the *New Rhenish Gazette*, the only really revolutionary man in the whole Assembly, told them that if they meant what they said, they had better give over talking, and declare the Imperial Lieutenant, the chief traitor to the country, an outlaw at once; then the entire compressed virtuous indignation of these parliamentary gentlemen burst out with an energy which they never found when the Government heaped insult after insult upon them.

Of course, for Wolff's proposition was the first sensible word spoken within the walls of St. Paul's Church; of course, for it was the very thing that was to be done, and such plain language going so direct to the purpose, could not but insult a set of sentimentalists, who were resolute in nothing but irresolution, and who, too cowardly to act, had once for all made up their minds that in doing nothing, they were doing exactly what was to be done. Every word which cleared up, like lightning, the infatuated, but intentional nebulosity of their minds, every hint that was adapted to lead them out of the labyrinth where they obstinated themselves to take up as lasting an abode as possible, every clear conception of matters as they actually stood, was, of course, a crime against the majesty of this Sovereign Assembly.

Shortly after the position of the honorable gentlemen in Frankfort became untenable, in spite of resolutions, appeals, interpellations, and proclamations, they retreated, but not into the insurgent districts; that would have been too resolute a step. They went to Stuttgart, where the Würtemberg Government kept up a sort of expectative neutrality. There, at last, they declared the Lieutenant of the Empire to have forfeited his power, and elected from their own body a Regency of five. This Regency at once proceeded to pass a Militia law, which was actually in all due force sent to all the Governments of Germany.

They, the very enemies of the Assembly, were ordered to levy forces in its defence! Then there was created — on paper, of course — an army for the defence of the National Assembly. Divisions, brigades, regiments, batteries, everything was regulated and ordained. Nothing was wanted but reality, for that army, of course, was never called into existence.

One last scheme offered itself to the General Assembly. The Democratic population from all parts of the country sent deputations to place itself at the disposal of the Parliament, and to urge it on to a decisive action. The people, knowing what the intentions of the Würtemberg Government were, implored the National Assembly to force that Government into an open and active participation with their insurgent neighbors. But no. The National Assembly, in going to Stuttgart, had delivered itself up to the tender mercies of the Würtemberg Government. The members knew it, and repressed the agitation among the people. They thus lost the last remnant of influence which they might yet have retained. They earned the contempt they deserved, and the Imperial Lieutenant put a stop to the Democratic farce by shutting up, on the 18th of June, 1849, the room where the Parliament met, and by ordering the members of the Regency to leave the country.

Next they went to Baden, into the camp of the insurrection; but there they were now useless. Nobody noticed them. The Regency, however, in the name of the Sovereign German people, continued to save the country by its exertions. It made an attempt to get recognized by foreign powers, by delivering *passports* to anybody who would accept of them. It issued proclamations, and sent commissioners to insurge those very districts of Würtemberg whose active assistance it had refused when it was yet time; of course, without effect. We have now under our eye an original report, sent to the Regency by one of these commissioners, Herr Roesler (member for Oels), the contents of which are rather characteristic. It is dated, Stuttgart,

June 30, 1849. After describing the adventures of half a dozen of these commissioners in a resultless search for cash, he gives a series of excuses for not having yet gone to his post, and then delivers himself of a most weighty argument respecting possible differences between Prussia, Austria, Bavaria, and Würtemberg, with their possible consequences. After having fully considered this, he comes, however, to the conclusion that there is no more chance. Next, he proposes to establish relays of trustworthy men for the conveyance of intelligence, and a system of espionage as to the intentions of the Würtemberg Ministry and the movements of the troops. This letter never reached its address, for when it was written the "Regency" had already passed entirely into the "foreign department," viz., Switzerland; and while poor Herr Roesler troubled his head about the intentions of the formidable ministry of a sixth-rate kingdom, a hundred thousand Prussian, Bavarian, and Hessian soldiers had already settled the whole affair in the last battle under the walls of Rastatt.

Thus vanished the German Parliament, and with it the first and last creation of the Revolution. Its convocation had been the first evidence that there actually *had been* a revolution in January; and it existed as long as this, the first modern German Revolution, was not yet brought to a close. Chosen under the influence of the capitalist class by a dismembered, scattered, rural population, for the most part only awaking from the dumbness of feudalism, this Parliament served to bring in one body upon the political arena all the great popular names of 1820-1848, and then to utterly ruin them. All the celebrities of middle class Liberalism were here collected. The bourgeoisie expected wonders; it earned shame for itself and its representatives. The industrial and commercial capitalist class were more severely defeated in Germany than in any other country; they were first worsted, broken, expelled from office in every individual State of Germany, and then put to rout, disgraced and hooted in the Central German Parliament. Political Liberalism, the rule of the bourgeoisie, be it under a Monarchical or Republican form of government, is forever impossible in Germany.

In the latter period of its existence, the German Parliament served to disgrace forever that section which had ever since March, 1848, headed the official opposition, the Democrats representing the interests of the small trading, and partially of the farming class. That class was, in May and June, 1849, given a chance to show its means of forming a stable Government in

Germany. We have seen how it failed; not so much by adverse circumstances as by the actual and continued cowardice in all trying movements that had occurred since the outbreak of the revolution; by showing in politics the same shortsighted, pusillanimous, wavering spirit, which is characteristic of its commercial operations. In May, 1849, it had, by this course, lost the confidence of the real fighting mass of all European insurrections, the working class. But yet, it had a fair chance. The German Parliament belonged to it, exclusively, after the Reactionists and Liberals had withdrawn. The rural population was in its favor. Two-thirds of the armies of the smaller States, one-third of the Prussian army, the majority of the Prussian Landwehr (reserve or militia), were ready to join it, if it only acted resolutely, and with that courage which is the result of a clear insight into the state of things. But the politicians who led on this class were not more clear-sighted than the host of petty tradesmen which followed them. They proved even to be more infatuated, more ardently attached to delusions voluntarily kept up, more credulous, more incapable of resolutely dealing with facts than the Liberals. Their political importance, too, is reduced below the freezing-point. But not having actually carried their commonplace principles into execution, they were, under *very* favorable circumstances, capable of a momentary resurrection, when this last hope was taken from them, just as it was taken from their colleagues of the “pure Democracy” in France by the *coup d’état* of Louis Bonaparte.

The defeat of the south-west German insurrection, and the dispersion of the German Parliament, bring the history of the first German insurrection to a close. We have now to cast a parting glance upon the victorious members of the counter-revolutionary alliance; we shall do this in our next letter.

London, September 24, 1852.

XX. THE LATE TRIAL AT COLOGNE.

December 22, 1852.

You will have ere this received by the European papers numerous reports of the Communist Monster Trial at Cologne, Prussia, and of its result. But as none of the reports is anything like a faithful statement of the facts, and as these facts throw a glaring light upon the political means by which the continent of Europe is kept in bondage, I consider it necessary to revert to this trial.

The Communist or Proletarian party, as well as other parties, had lost, by suppression of the rights of association and meeting, the means of giving to itself a legal organization on the Continent. Its leaders, besides, had been exiled from their countries. But no political party can exist without an organization; and that organization which both the Liberal bourgeois and the Democratic shopkeeping class were enabled more or less to supply by the social station, advantages, and long-established, every-day intercourse of their members, the proletarian class, without such social station and pecuniary means, was necessarily compelled to seek in secret association. Hence, both in France and Germany, sprung up those numerous secret Societies which have, ever since 1849, one after another, been discovered by the police, and prosecuted as conspiracies; but if many of them were really conspiracies, formed with the actual intention of upsetting the Government for the time being, — and he is a coward that under certain circumstances would not conspire, just as he is a fool who, under other circumstances, would do so; — there were some other Societies which were formed with a wider and more elevated purpose, which knew that the upsetting of an existing Government was but a passing stage in the great impending struggle, and which intended to keep together and to prepare the party, whose nucleus they formed, for the last decisive combat which must, one day or another, crush forever in Europe the domination, not of mere “tyrants,” “despots” and “usurpers,” but of a power far superior, and far more formidable than theirs; that of capital over labor.

The organization of the advanced Communist party in Germany was of this kind. In accordance with the principles of the “Manifesto” (published in 1848), and with those explained in the series of articles on “Revolution and

Counter-Revolution in Germany,” published in the *New York Daily Tribune*, this party never imagined itself capable of producing, at any time and at its pleasure, that revolution which was to carry its ideas into practice. It studied the causes that had produced the revolutionary movement in 1848, and the causes that made them fail. Recognizing the social antagonism of classes at the bottom of all political struggles, it applied itself to the study of the conditions under which one class of society can and must be called on to represent the whole of the interests of a nation, and thus politically to rule over it. History showed to the Communist party how, after the landed aristocracy of the Middle Ages, the monied power of the first capitalists arose and seized the reins of Government; how the social influence and political rule of this financial section of capitalists was superseded by the rising strength since the introduction of steam, of the manufacturing capitalists, and how at the present moment two more classes claim their turn of domination, the petty trading class and the industrial working class. The practical revolutionary experience of 1848-1849 confirmed the reasonings of theory, which led to the conclusion that the Democracy of the petty traders must first have its turn, before the Communist working class could hope to permanently establish itself in power and destroy that system of wage-slavery which keeps it under the yoke of the bourgeoisie. Thus the secret organization of the Communists could not have the direct purpose of upsetting the present Governments of Germany. Being formed to upset not these, but the insurrectionary Government, which is sooner or later to follow them, its members might, and certainly would, individually, lend an active hand to a revolutionary movement against the present *status quo* in its turn; but the preparation of such a movement, otherwise than by spreading of Communist opinions by the masses, could not be an object of the Association. So well was this foundation of the Society understood by the majority of its members, that when the place-hunting ambition of some tried to turn it into a conspiracy for making an extempore revolution they were speedily turned out.

Now, according to no law upon the face of the earth, could such an Association be called a plot, a conspiracy for purposes of high treason. If it was a conspiracy, it was one against, not the existing Government, but its probable successor. And the Prussian Government was aware of it. That was the cause why the eleven defendants were kept in solitary confinement during eighteen months, spent, on the part of the authorities, in the strangest

judicial feats. Imagine, that after eight months' detention, the prisoners were remanded for some months more, "there being no evidence of any crime against them!" And when at last they were brought before a jury, there was not a single overt act of a treasonable nature proved against them. And yet they were convicted, and you will speedily see how.

One of the emissaries of the society was arrested in May, 1851, and from documents found upon him, other arrests followed. A Prussian police officer, a certain Stieber, was immediately ordered to trace the ramifications, in London, of the pretended plot. He succeeded in obtaining some papers connected with the above-mentioned seceders from the society, who had, after being turned out, formed an actual conspiracy in Paris and London. These papers were obtained by a double crime. A man named Reuter was bribed to break open the writing-desk of the secretary of the Society, and steal the papers therefrom. But that was nothing yet. This theft led to the discovery and conviction of the so-called Franco-German plot, in Paris, but it gave no clue as to the great Communist Association. The Paris plot, we may as well here observe, was under the direction of a few ambitious imbeciles and political *chevaliers d'industrie* in London, and of a formerly convicted forger, then acting as a police spy in Paris; their dupes made up, by rabid declamations and blood-thirsty rantings, for the utter insignificance of their political existence.

The Prussian police, then, had to look out for fresh discoveries. They established a regular office of secret police at the Prussian Embassy in London. A police agent, Greif by name, held his odious vocation under the title of an attaché to the Embassy — a step which should suffice to put all Prussian embassies out of the pale of international law, and which even the Austrians have not yet dared to take. Under him worked a certain Fleury, a merchant in the city of London, a man of some fortune and rather respectably connected, one of those low creatures who do the basest actions from an innate inclination to infamy. Another agent was a commercial clerk named Hirsch, who, however, had already been denounced as a spy on his arrival. He introduced himself into the society of some German Communist refugees in London, and they, in order to obtain proofs of his real character, admitted him for a short time. The proofs of his connection with the police were very soon obtained, and Herr Hirsch, from that time, absented himself. Although, however, he thus resigned all opportunities of gaining the information he was paid to procure, he was not inactive. From his retreat in

Kensington, where he never met one of the Communists in question, he manufactured every week pretended reports of pretended sittings of a pretended Central Committee of that very conspiracy which the Prussian police could not get hold of. The contents of these reports were of the most absurd nature; not a Christian name was correct, not a name correctly spelt, not a single individual made to speak as he would be likely to speak. His master, Fleury, assisted him in this forgery, and it is not yet proved that "Attaché" Greif can wash his hands of these infamous proceedings. The Prussian Government, incredible to say, took these silly fabrications for gospel truth, and you may imagine what a confusion such depositions created in the evidence brought before the jury. When the trial came on, Herr Stieber, the already mentioned police officer, got into the witness-box, swore to all these absurdities, and, with no little self-complacency, maintained that he had a secret agent in the very closest intimacy with those parties in London who were considered the prime movers in this awful conspiracy. This secret agent was very secret indeed, for he had hid his face for eight months in Kensington, for fear he might actually see one of the parties whose most secret thoughts, words and doings, he pretended to report week after week.

Messrs. Hirsch and Fleury, however, had another invention in store. They worked up the whole of the reports they had made into an "original minute book" of the sittings of the Secret Supreme Committee, whose existence was maintained by the Prussian police; and Herr Stieber, finding that this book wondrously agreed with the reports already received from the same parties, at once laid it before the jury, declaring upon his oath that after serious examination, and according to his fullest conviction, that book was genuine. It was then that most of the absurdities reported by Hirsch were made public. You may imagine the surprise of the pretended members of that Secret Committee when they found things stated of them which they never knew before. Some who were baptized William were here christened Louis or Charles; others, at the time they were at the other end of England, were made to have pronounced speeches in London; others were reported to have read letters they never had received; they were made to have met regularly on a Thursday, when they used to have a convivial reunion, once a week, on Wednesdays; a working man, who could hardly write, figured as one of the takers of minutes, and signed as such; and they all of them were made to speak in a language which, if it may be that of Prussian police

stations, was certainly not that of a reunion in which literary men, favorably known in their country, formed the majority. And, to crown the whole, a receipt was forged for a sum of money, pretended to have been paid by the fabricators to the pretended secretary of the fictitious Central Committee for this book; but the existence of this pretended secretary rested merely upon a hoax that some malicious Communist had played upon the unfortunate Hirsch.

This clumsy fabrication was too scandalous an affair not to produce the contrary of its intended effect. Although the London friends of the defendants were deprived of all means to bring the facts of the case before the jury — although the letters they sent to the counsel for the defence were suppressed by the post — although the documents and affidavits they succeeded in getting into the hands of these legal gentlemen were not admitted in evidence, yet the general indignation was such that even the public accusers, nay, even Herr Stieber — whose oath had been given as a guarantee for the authenticity of that book — were compelled to recognize it as a forgery.

This forgery, however, was not the only thing of the kind of which the police was guilty. Two or three more cases of the sort came out during the trial. The documents stolen by Reuter were interpolated by the police so as to disfigure their meaning. A paper, containing some rabid nonsense, was written in a handwriting imitating that of Dr. Marx, and for a time it was pretended that it had been written by him, until at last the prosecution was obliged to acknowledge the forgery. But for every police infamy that was proved as such, there were five or six fresh ones brought forward, which could not, at the moment, be unveiled, the defence being taken by surprise, the proofs having to be got from London, and every correspondence of the counsel for the defence with the London Communist refugees being in open court treated as complicity in the alleged plot!

That Greif and Fleury are what they are here represented to be has been stated by Herr Stieber himself, in his evidence; as to Hirsch, he has before a London magistrate confessed that he forged the “minute book,” by order and with the assistance of Fleury, and then made his escape from this country in order to evade a criminal prosecution.

The Government could stand few such branding disclosures as came to light during the trial. It had a jury — six nobles, two Government officials. These were not the men to look closely into the confused mass of evidence

heaped before them during six weeks, when they heard it continually dinned into their ears that the defendants were the chiefs of a dreadful Communist conspiracy, got up in order to subvert everything sacred — property, family, religion, order, government and law! And yet, had not the Government, at the same time, brought it to the knowledge of the privileged classes, that an acquittal in this trial would be the signal for the suppression of the jury; and that it would be taken as a direct political demonstration — as a proof of the middle-class Liberal Opposition being ready to unite even with the most extreme revolutionists — the verdict would have been an acquittal. As it was, the retroactive application of the new Prussian code enabled the Government to have seven prisoners convicted, while four merely were acquitted, and those convicted were sentenced to imprisonment varying from three to six years, as you have, doubtless, already stated at the time the news reached you.

London, December 1, 1852.

The Biographies

University of Bonn, Germany — in October 1835 at the age of 17, Marx wished to study philosophy and literature at Bonn; however, his father insisted on law as a more practical field. While at the University at Bonn, Marx joined the Poets' Club, a group containing political radicals that were monitored by the police.

University of Berlin, Germany. Although Marx's grades at Bonn in the first term were good, they soon deteriorated, leading his father to force a transfer to the more serious and academic University of Berlin.

III. YEARS OF AGITATION AND VARYING FORTUNES.

IV. THE MARXIAN SYSTEM.

CONCLUSION.

INTRODUCTION.

I. The Significance of Marx.

Karl Marx belongs to the ranks of those philosophical and sociological thinkers who throw potent thought-ferment into the world, and set in motion the masses of mankind. They awaken slumbering doubts and contradictions. They proclaim new modes of thought, new social forms. Their systems may sooner or later become obsolete, and the ruthless march of time may finally overthrow their intellectual edifice; meanwhile, however, they stimulate into activity the minds of countless men, inflame countless human hearts, imprinting on them characteristics which are transmitted to coming generations. This is the grandest and finest work to which any human being can be called. Because these thinkers have lived and worked, their contemporaries and successors think more clearly, feel more intensely, and are richer in knowledge and self-consciousness.

The history of philosophy and of social science is comprised in such systems and generalisations. They are the index to the annals of mankind. None of these systems is complete, none comprehends all human motives and capacities, none exhausts all the forces and currents of human society. They all express only fragmentary truths, which, however, become effective and achieve success because they are shining lights amidst the intellectual confusion of the generation which gives them birth, bringing it to a consciousness [x]of the questions of the time, rendering its further development less difficult, and enabling its strongest spirits to stand erect, with fixity of purpose, in critical periods.

Hegel expresses himself in a similar sense where he remarks: "When the refutation of a philosophy is spoken of, this is usually meant in an abstract negative (completely destructive) sense, so that the confuted philosophy has no longer any validity whatever, and is set aside and done with. If this be so, the study of the history of philosophy must be regarded as a thoroughly depressing business, seeing that this study teaches that every system of philosophy which has arisen in the course of time has found its refutation. But if it is as good as granted that every philosophy has been refuted, yet at the same time it must be also asserted that no philosophy has been refuted, nor ever can be refuted ... for every philosophical system is to be considered as the presentation of a particular moment or a particular stage in the

evolutionary process of the idea. The history of philosophy ... is not, in its totality, a gallery of the aberrations of the human intellect, but is rather to be compared to a pantheon of deities.”

— (“Hegel, Encyclopædia,” vol. 1, section 86, note 2.)

What Hegel says here about philosophy is true also of systems of social science, and styles and forms in art. The displacement of one system by another reflects the historical sequence of the various stages of social evolution. The characteristic which is common to all these systems is their vitality.

In spite of their defects and difficulties there surges through them a living spirit from the influence of which [xi]contemporaries cannot escape. Opponents may put themselves to endless trouble to contradict such systems, and show up their shortcomings and inconsistencies, and yet, with all their pains, they do not succeed in attaining their object; their logical sapping and mining, their passionate attacks break against the vital spirit which the creative genius has breathed into his work. The deep impression made on us by this vitality is one of the main factors in the formation of our judgments upon scientific and artistic achievements. Mere formal perfection and beauty through which the life of the times does not throb can never create this impression.

Walter Scott, who was often reproached with defects and inconsistencies in the construction of his novels, once made answer with the following anecdote: A French sculptor, who had taken up his abode in Rome, was fond of taking to the Capitol his artistically inclined countrymen who were travelling in Italy, to show them the equestrian statue of Marcus Aurelius, on which occasions he was at pains to demonstrate that the horse was defectively modelled, and did not meet the requirements of anatomy. After one of these criticisms a visitor urged him to prove his case in a concrete form by constructing a horse on correct artistic principles. The critic set to work, and when, after the lapse of a year, his friends were again visiting Rome, exhibited to them his horse. It was anatomically perfect. Proudly he had it brought to the Capitol, in order to compare both productions and so celebrate his triumph. Quite absorbed in his critical comparison, the French sculptor after a while gave way to a burst of genuine artistic feeling, which caused him pathetically to exclaim, “*Et pourtant [xii]cette bête-là est vivante, et la mienne est morte!*” (And yet that animal is alive, while mine is dead.)

Quite a number of Marxian critics find themselves in the same position as the hypercritical French sculptor. Their formal and logically complete economic doctrines and systems of historical philosophy, provided with pedantically correct details and definitions, remain dead and ineffective. They do not put us into contact with the relations of the time, whereas Marx has bequeathed both to the educated and the uneducated, to his readers and to non-readers, a multitude of ideas and expressions relating to social science, which have become current throughout the whole world.

In Petrograd and in Tokio, in Berlin and in London, in Paris and in Pittsburg, people speak of capital and of the capitalist system, of means of production and of the class struggle; of Reform and Revolution; of the Proletariat and of Socialism. The extent of Marx's influence is shown by the economic explanation of the world-war, which is even accepted by the most decided opponents of the materialist conception of history. A generation after Marx's death, the sovereignty of Capital shrinks visibly, works' committees and shops' stewards interfere with the productive processes, Socialists and Labour men fill the Parliaments, working men and their representatives rise to or take by storm the highest position of political power in States and Empires. Many of their triumphs would scarcely have received Marx's approval. His theory, white-hot with indomitable passion, demanded that the new tables of the Law should be given to men amidst thunder and lightning. But still the essential thing is that the proletariat is loosening its bonds, even [xiii]if it does not burst them noisily asunder. We find ourselves in the first stages of the evolution of Socialist society. Through whatever forms this evolutionary process may pass in its logical development, this much is certain, that only by active thought on the part of Socialists and by the loyal co-operation of the workers can it be brought to its perfection.

We are already using Hegelian expressions, and must therefore pause here to note briefly Hegel's contribution to the subject. Without a knowledge of this, no one can be in a position to appreciate the important factors in the life and influence of Marx, or even to understand his first intellectual achievements during his student years.

II. The Work of Hegel.

Until towards the end of the eighteenth century, learned and unlearned, philosophers and philistines, had some such general notions as the following. The world has either been created, or it has existed from eternity. It is either governed by a personal, supernatural god or universal spirit, or it is kept going by nature, like some delicate machine. It exists in accordance with eternal laws, and is perfect, ordained to fulfil some design, and constant. The things and beings which are found in it are divided into kinds, species and classes. All is fixed, constant and eternal. Things and beings are contiguous in space, and succeed one another in time, as they have done ever since time was. It is the same with the incidents and events of the world and of mankind. Such common [xiv]proverbs as “There is nothing new under the sun” and “History repeats itself” are but the popular expression of this view.

Correlative to this philosophy was Logic, or the science of the laws of thinking (Greek logos — reason, word). It taught how men should use their reason, how they should express themselves reasonably, how concepts arise (in what manner, for example, the human understanding arrived at the concepts stone, tree, animal, man, virtue, vice, etc.); further, how such concepts are combined into judgments (propositions), and finally, how conclusions are drawn from these judgments. This logic exhibited the intellectual processes of the human mind. It was founded by the Greek philosopher, Aristotle (384 to 322 B.C.), and remained essentially unaltered until the beginning of the nineteenth century, in the same way as our whole conception of the universe remained unchanged. This science of human intellectual processes was based on three original laws of thought, which best characterise it. Just as an examining magistrate looks a prisoner in the face, and identifies him, so that uncertainty and contradiction may be avoided, so this logic began by establishing the identity of the conceptions with which it was to operate. Consequently, it established as the first law of thought the Principle of Identity, which runs as follows: $A = A$, i.e., each thing, each being, is like itself; it possesses an individuality of its own, peculiar to itself. To put it more clearly, this principle affirms that the earth is the earth, a state is a state, Capital is Capital, Socialism is Socialism.

From this proceeds the second law of thought, the Principle of Contradiction. A cannot be A and not — A. Or following our example given above, the [xv]earth cannot be the earth and a ball of fire; a State cannot be a State and an Anarchy; Capital cannot be Capital and Poverty;

Socialism cannot be Socialism and Individualism. Therefore there must be no contradictions, for a thing which contradicts itself is nonsense; where, however, this occurs either in actuality or in thought, it is only an accidental exception to the rule, as it were, or a passing and irregular phenomenon.

From this law of thought follows directly the third, viz., the Principle of the Excluded Middle. A thing is either A or non-A; there is no middle term. Or, according to our example, the earth is either a solid body, or, if it is not solid, it is no earth; there is no middle term. The State is either monarchical, or, if it is not monarchical, it is no State. Capitalism is either oppressive, or altogether not Capitalism. Socialism is either revolutionary, or not Socialism at all; there is no middle term. (Socialism is either reformist, or not Socialism at all; there is no middle term.)

With these three intellectual laws of identity, of contradiction, and of the excluded middle, formal logic begins.

It is at once apparent that this logic operates with rigid, constant, unchanging, dogmatic conceptions, something like geometry, which deals with definitely bounded spatial forms. Such was the rationale of the old world-philosophy.

By the beginning of the nineteenth century a new conception of the world had begun to make its way. The world, as we see it, or get to know it from books, was neither created, nor has it existed from time immemorial, but has developed in the course of uncounted thousands of years, and is still in process [xvi]of development. It has traversed a whole series of changes, transformations, and catastrophes. The earth was a gaseous mass, then a ball of fire; the species and classes of things and beings which exist on the earth have partly arisen by gradual transition from one sort into another, and partly made their appearance as a result of sudden changes. And in human history it is the same as in nature; the form and significance of the family, of the State, of production, of religion, of law, etc., are subjected to a process of development. All things are in flux, in a state of becoming, of arising and disappearing. There is nothing rigid, constant, unchanging in the Cosmos.

In view of the new conception, the old formal logic could no longer satisfy the intellect; it could not adequately deal with things in a state of evolution. In ever-increasing measure it became impossible for the thinker to work with hard and fast conceptions. From the beginning of the nineteenth century a new logic was sought, and it was G.W.F. Hegel (1770-1831) who made a comprehensive and thoroughly painstaking endeavour to

formulate a new logic in accordance with the universal process of evolution. This task appeared to him to be the more urgent, as his whole philosophy aimed at bringing thought and being, reason and the universe, into the closest connection and agreement, dealing with them as inseparable from each other, regarding them as identical, and representing the universe as the gradual embodiment of Reason. "What is reasonable is real; what is real is reasonable." The task of philosophy is to comprehend what is. Every individual is the child of his time. Even philosophy is its time grasped in thought. No individual can overleap his time. [xvii](Pref. to Phil, of Law.) It is evident that, in his way, Hegel was no abstract thinker, divorced from actuality, and speculating at large. Rather he set himself to give material content to the abstract and purely ideal, to make it concrete, in fact. The idea without reality, or reality without the idea, seemed to him unthinkable. Accordingly his logic could not deal merely with the laws of thought, but must at the same time take account of the laws of cosmic evolution. Merely to play with the forms of thought, and to fence with ideas, as the old logicians, especially in the Middle Ages, were wont to do, seemed to him a useless, abstract, unreal operation. He, therefore, created a science of thinking, which formulated not only the laws of thought, but also the laws of evolution, albeit, unfortunately, in a language which offered immense difficulties to his readers.

The essence of his logic is the dialectic.

By dialectic the old Greeks understood the art of discourse and rejoinder, the refutation of an opponent by the destruction of his assertions and proofs, the bringing into relief of the contradictions and antitheses. When examined closely, this art of discussion, in spite of its contradictory and apparently negative (destructive) intellectual work, is seen to be very useful, because, out of the clash of opposing opinions, it brings forth the truth and stimulates to deeper thought. Hegel seized hold of this expression, and named his logical method after it. This is the dialectical method, or the manner of conceiving the things and beings of the universe as in the process of becoming, through the struggle of contradictory elements and their resolution. With its aid, he brings to judgment the three original laws of thought which [xviii] have already been alluded to. The principle of identity is an abstract, incomplete truth, for it separates a thing from the variety of other things, and its relations to them. Everybody will see this to be true. Let us take the proposition: the earth is the earth. Whoever hears the first

three words of this proposition naturally expects that what is predicated of the earth should tell him something which distinguishes the earth from other things. Instead of this, he is offered an empty, hard and fast identity, the dead husk of an idea. If the principle of identity is at best only an incomplete truth, the principles of contradiction and of the excluded middle are complete untruths. Far from making a thought nonsense, contradiction is the very thing which unfolds and develops the thought, and hence, too, the object which it expresses. It is precisely opposition, or antithesis, which sets things in motion, which is the mainspring of evolution, which calls forth and develops the latent forces and powers of being. Had the earth as a fiery, gaseous mass remained in that state, without the contradiction, that is, the cooling and condensation, taking place, then no life would have appeared on it. Had the State remained autocratic, and the contradictory principle, middle-class freedom, been absent, then the life of the State would have become rigid, and the bloom of culture rendered impossible. Had Capitalism remained without its proletarian contradiction, then it would have reverted to an industrial feudalism. It is the contradiction, or the antithesis, which brings into being the whole kingdom of the potentialities and gifts of nature and of humanity. Only when the contradictory begins to reveal itself does evolution to a higher plane of thought and [xix]existence begin. It is obvious that we are not concerned here with logical contradictions, which usually arise from unclear thinking or from confusion in the presentation of facts; Hegel, and after him Marx, dealt rather with real contradictions, with antitheses and conflicts, as they arise of themselves in the process of evolution of things and conditions.

The thing or the being, against which the contradiction operates, was called by Hegel the Positive, and the contradiction, the antagonistic element, or the antithesis, he called the Negation. As may be seen from our example, this negation is not mere annihilation, not a resolution into nothing, but a clearing away and a building up at the same time; a disappearance and a coming into existence; a movement to a higher stage. Hegel says in this connection: "It has been hitherto one of the rooted prejudices of logic and a commonly accepted belief that the contradiction is not so essential or so inherent a characteristic (in thought and existence) as the identity. Yet in comparison with it the identity is, in truth, but the characteristic of what is simply and directly perceived, of lifeless existence. The contradiction, however, is the source of all movement and life; only in

so far as it contains a contradiction can anything have movement, power, and effect.”

The part played by the contradiction, the antithesis, or the negation very easily escapes a superficial observer. He sees, indeed, that the world is filled with a variety of things, and that where anything is there is also its opposite; e.g., existence — non-existence, cold — heat, light — darkness, mildness — harshness, pleasure — pain, joy — sorrow, riches — poverty, Capital — Labour, life — death, virtue — vice, [xx]Idealism — Materialism, Romanticism — Classicism, etc., but superficial thought does not realise that it is faced with a world of contradictions and antitheses; it only knows that the world is full of varied and manifold things. “Only active reason,” says Hegel, “reduced the mere multiplicity and diversity of phenomena to antithesis. And only when pushed to this point do the manifold phenomena become active and mutually stimulating, producing the state of negation, which is the very heart-beat of progress and life.” Only through their differentiation and unfolding as opposing forces and factors is further progress beyond the antithesis to a higher positive stage made possible. “Where, however,” continues Hegel, “the power to develop the contradiction and bring it to a head is lacking, the thing or the being is shattered on the contradiction.” — (Hegel, “Science of Logic,” Pt. 1, Sec. 2, pp. 66, 69, 70.)

This thought of Hegel’s is of extraordinary importance for the understanding of Marxism. It is the soul of the Marxian doctrine of the class-struggle, nay, of the whole Marxian system. One may say that Marx is always on the look-out for contradictions within the social development, for wherever the contradiction (antithesis — class struggle) shows itself, there begins, according to Marx-Hegel, the progress to a higher plane.¹

We have now become familiar with two expressions of the dialectical method, the positive and the negation. We have seen the first two stages of the process of growth in thought and in reality. The process is not yet complete. It still requires a third stage. [xxi]This third step Hegel called the Negation of the Negation. With the continued operation of the negation, a new thing or being comes into existence.

To revert to our examples: the complete cooling and condensation of the earth’s crust: the rise of the middle-class State: the victory of the Proletariat: these things represent the suspension or the setting aside of the Negation; the contradiction is thus resolved, and a new stage in the process of

evolution is reached. The expressions Positive (or affirmation), Negation, and Negation of the Negation, are also known as thesis, antithesis, and synthesis.

In order to understand this more distinctly, and to visualise it, let us consider an egg. It is something positive, but it contains a germ, which, awakening to life, gradually consumes (i.e., negatives) the contents of the egg. This negation is, however, no mere destruction and annihilation; on the contrary, it results in the germ developing into a living thing. The negation being complete, the chick breaks through the egg shell. This represents the negation of the negation, whereby there has arisen something organically higher than an egg.

This mode of procedure in human thinking and in the operations of nature and history Hegel called the dialectical method, or the dialectical process. It is evident that the dialectic is at the same time a method of investigation and a philosophy. Hegel outlines his dialectic in the following words:

“The only thing which is required for scientific progress, an elementary principle for the understanding of which one should really strive, is the recognition of the logical principle that the negative is just as much a positive, or that the contradictory does not [xxii]resolve into nothing, into an abstract nothingness, but actually only into the negation of a special content.... In so far as the resultant, the negation, is a definite negation, it has a content. It is a new conception, but a higher and richer conception than the preceding one; for it has been enriched by the negation or antithesis of this; it therefore contains it and more than contains it, being indeed the synthetic unity of itself and its contrary. In this way the system of concepts has to be formed — and is to be perfected by a continual and purely intellectual process which is independent of outside influences.” — (Hegel, “Science of Logic” (German), Bk. I., Introduction.)

The dialectical process completes itself not only by gradual transitions, but also by leaps. Hegel remarks:

“It has been said that there are no sudden leaps in nature, and it is a common notion that things have their origin through gradual increase or decrease. But there is also such a thing as sudden transformation from quantity into quality. For example, water does not become gradually hard on cooling, becoming first pulpy and ultimately attaining the rigidity of ice, but turns hard at once. If the temperature be lowered to a certain degree, the

water is suddenly changed into ice, i.e., the quantity — the number of degrees of temperature — is transformed into quality — a change in the nature of the thing.” — (“Logic” (German), Pt. 1, Sec. 1, p. 464, Ed. 1841.)

Marx handled this method with unsurpassed mastery; with its aid he formulated the laws of the evolution of Socialism. In his earliest works, “The Holy Family” (1844) and the “Poverty of [xxiii]Philosophy” (1847), written when he was formulating his materialist conception of history, as also in his “Capital,” it is with the dialectic of Hegel that he investigates these laws.

“Proletariat and Riches (later Marx would have said Capital) are antitheses. As such they constitute a whole; both are manifestations of the world of private property. The question to be considered is the specific position which both occupy in the antithesis. To describe them as two sides of a whole is not a sufficient explanation. Private property as private property, as riches, is compelled to preserve its own existence, and along with it that of its antithesis, the Proletariat. Private property satisfied in itself is the positive side of the antithesis. The Proletariat, on the other hand, is obliged, as Proletariat, to abolish itself, and along with it private property, its conditioned antithesis, which makes it the Proletariat. It is a negative side of the antithesis, the internal source of unrest, the disintegrated and disintegrating Proletariat.... Within the antithesis, therefore, the owner of private property is the conservative, and the proletarian is the destructive party. From the former proceeds the action of maintaining the antithesis, from the latter the action of destroying it. From the point of view of its national, economic movement, private property is, of course, continually being driven towards its own dissolution, but only by an unconscious development which is independent of it, and which exists against its will, and is limited by the nature of things; only, that is, by creating the Proletariat as proletariat, poverty conscious of its own physical and spiritual poverty, and demoralised humanity conscious of its own [xxiv]demoralisation and consequently striving against it.

“The Proletariat fulfils the judgment which private property by the creation of the Proletariat suspends over itself, just as it fulfils the judgment which wage-labour suspends over itself in creating alien riches and its own condemnation. If the Proletariat triumphs, it does not thereby become the absolute side of society, for it triumphs only by abolishing itself and its

opposite. In this way both the Proletariat and its conditioned opposite, private property, are done away with.”²

The dialectical method is again described in a few sentences on pages 420-421 of the third volume of “Capital” (German), where we read: “In so far as the labour process operates merely between man and nature, its simple elements are common to every form of its social development. But any given historical form of this process further develops its material foundations and its social forms. When it has attained a certain degree of maturity the given historical form is cast off and makes room for a higher one. That the moment of such a crisis has arrived is shown as soon as there is a deepening and widening of the contradiction and antithesis between the conditions of distribution, and consequently also the existing historical form of the conditions of production corresponding to them, on the one hand, and the forces of production, productive capacity, and the state of evolution of its agents, on the other. There then arises a conflict between the material development of production and its corresponding social form.”

[xxv]But the Hegelian dialectic appears most strikingly in the famous twenty-fourth chapter (sec. 7) of the first volume of “Capital” (German), where the evolution of capitalism from small middle-class ownership through all phases up to the Socialist revolution is comprehensively outlined in bold strokes: “The capitalist method of appropriation, which springs from the capitalist method of production, and therefore capitalist private property, is the first negation of individual private property based on one’s own labour. But capitalist production begets with the inevitableness of a natural process its own negation. It is the negation of the negation.” Here we have the three stages: the thesis — private property; the antithesis — capitalism; the synthesis — common ownership.

Of critical social writers outside Germany it was Proudhon, in particular, who, in his works “What is Property?” and “Economic Contradictions, or the Philosophy of Poverty” (1840, 1846), attempted to use the Hegelian dialectic. The fact that he gave his chief book the title “Economic Contradictions” shows that Proudhon was largely preoccupied with Hegel. Nevertheless, he did not get below the surface; he used the Hegelian formulæ quite mechanically, and lacked the conception of an immanent process of development (the forward-impelling force within the social organism).

If we look at the dialectical method as here presented, Hegel might be taken for a materialist thinker. Such a notion would be erroneous. For Hegel is an idealist: the origin and essence of the process of growth is to be sought, according to him, not in material forces, but in the logical idea, reason, the universal spirit, the absolute, or — in its religious [xxvi]expression — God. Before He created the world He is to be regarded as an Idea, containing within itself all forms of being, which it develops dialectically. The idea creates for itself a material embodiment; it first expresses itself in the objects of inorganic nature; then in plants, organisms wherein life awakens; then in animals, in which the Idea attains to the twilight of reason; finally, in men, where reason rises into mind and achieves self-consciousness and freedom. As self-conscious mind it expresses itself in the history of peoples, in religion, art and philosophy, in human institutions, in the family and in law, until it realises itself in the State as its latest and highest object.

According to Hegel, then, the universal Idea develops into Godhead in proportion as the material world rises from the inorganic to the organic, and, finally, to man. In the mental part of man, the Idea arrives at self-consciousness and freedom and becomes God. In his cosmology, Hegel is a direct descendant of the German mystics, Sebastian Franck and Jacob Boehme. He was in a much higher degree German than any of the German philosophers since Leibnitz.

The strangest thing, however, is that Germanism, Protestantism, and the Prussian State appeared to Hegel as the highest expression of the universal mind. Particularly the Prussian State as it existed before March, 1848, with its repudiation of all middle-class reforms and liberalism (of any kind), and its basis of strong governmental force.

There is little purpose in trying to acquire a logical conception of Hegelian cosmology. It is not only idealist, but, as we said, mystical; it is as inconceivable to human reason as the biblical; it is irrational, and lies beyond the sphere of [xxvii]reason. Making the universe arise out of pure reason, out of the logical idea, developing through the dialectical process with a consciousness of freedom, it yet concludes in unreason and an obstinate determinism. In Liberalism Hegel saw only a simple negation, a purely destructive factor, which disintegrates the State and resolves it into individuals, thus depriving it of all cohesion and organising strength. He blamed Parliamentarism for demanding “that everything should take place

through their (the individuals) expressed power and consent. The will of the many overturns the Ministry, and what was the Opposition now takes control, but, so far as it is the Government, the latter finds the many against it. Thus agitation and unrest continue. This collision, this knot, this problem, is what confronts history, a problem which it must resolve at some future time.” One would have thought that it was precisely Parliamentarism, with its unrest and agitation, its antitheses and antagonisms, which would have had a special attraction for Hegel, but nevertheless he turned aside from it. How is this to be explained?

Hegel’s relation to the Prussian State is to be accounted for by his strong patriotic sentiments. His disposition inclined him strongly to nationalism in politics. In his early manhood he witnessed the complete dissolution of the German Empire, and deeply bewailed the wretchedness of German conditions. He wrote: “Germany is no longer a State; even the wars which Germany waged have not ended in a particularly honourable manner for her. Burgundy, Alsace, Lorraine have been torn away. The Peace of Westphalia has often been alluded to as Germany’s Palladium, although by it the complete [xxviii]dismemberment of Germany has only been established more thoroughly than before. The Germans have been grateful to Richelieu, who destroyed their power.” On the other hand, the achievements of Prussia in the Seven Years’ War, and in the War of Liberation against the French, awoke in him the hope that it was this State which could save Germany. To this thought he gave eloquent and enthusiastic expression in his address at the opening of his Berlin lectures in October, 1818, and also in his lecture on Frederick the Great. Hegel therefore rejected everything which seemed to him to spell a weakening of the Prussia State power. The dialectician was overcome by national feelings.

However, Hegel’s place in the history of thought rests, not on his explanations of the creation of the world, nor on his German nationalist politics, but upon the dialectical method. In exploring, by means of this method, the wide expanse of human knowledge, he scattered an astonishing abundance of materialistic and strictly scientific observations and suggestions, and inspired his pupils and readers with a living conception of history, of the development of mankind to self-consciousness and freedom, thus rendering them capable of pushing their studies further, and emancipating themselves from all mysticism. As an example of the

materialist tendency of his philosophy, the following references will serve. His “Philosophy of History” contains a whole chapter upon the geographical foundations of universal history. In this chapter he expresses himself — quite contrary to his deification of the State — as follows: “A real State and a real central government only arise when the distinction of classes is already given, when Riches and Poverty have become very great, and such [xxix]conditions have arisen that a great multitude can no longer satisfy their needs in the way to which they have been accustomed.” Or take his explanation of the founding of colonies by the Greeks.

“This projecting of colonies, particularly in the period after the Trojan War until Cyrus, is here a peculiar phenomenon, which may thus be explained: in the individual towns the people had the governing power in their hands, in that they decided the affairs of State in the last resort. In consequence of the long peace, population and development greatly increased, and quickly brought about the accumulation of great riches, which is always accompanied by the phenomenon of great distress and poverty. Industry, in our sense, did not exist at that time, and the land was speedily monopolised. Nevertheless, a section of the poorer classes would not allow themselves to be depressed to the poverty line, for each man felt himself to be a free citizen. The sole resource, therefore, was colonisation.”

Or even the following passage, which conceives the philosophical system merely as the result and reflection of the accomplished facts of existence, and therefore rejects all painting of Utopias: “Besides, philosophy comes always too late to say a word as to how the world ought to be. As an idea of the universe, it only arises in the period after reality has completed its formative process and attained its final shape. What this conception teaches is necessarily demonstrated by history, namely, that the ideal appears over against the real only after the consummation of reality, that the ideal reconstructs the same world, comprehended in the substance of reality, in the form of an intellectual realm. A form of life has become old when philosophy paints its grey on grey, [xxx]and with grey on grey it cannot be rejuvenated but only recognised. The owl of Minerva begins its flight only with the falling twilight.” — Preface to the “Philosophy of Law.”

No materialist could have said this better: the owl — the symbol of wisdom — only begins her flight in the evening, after the busy activities of the world are over. Thus we have first the universe, and then thought; first existence, and then consciousness.

Hegel himself was therefore an example of his own teaching that contradictory elements are to be found side by side. His mind contained both idealism and realism, but he did not bring them by a process of reasoning to the point of acute contradiction in order to reach a higher plane of thought. And as he regarded it as the task of philosophy to recognise the principle of things, and to follow it out systematically and logically throughout the whole vast domain of reality, and as further, owing to his mystical bent, he asserted the idea to be the ultimate reality, he remained a consistent Idealist.

The Conservatism of Hegel, who was the philosophical representative of the Prussian State, was, however, sadly incompatible with the awakening consciousness of the German middle class, which, in spite of its economic weakness, aspired to a freer State constitution, and greater liberty of action. These aspirations were already somewhat more strongly developed in the larger towns and industrial centres of Prussia and the other German States. The Young Hegelians³ championed this middle-class awakening in [xxxi]the philosophical sphere, just as “Young Germany” (Heine, Boerne, etc.) did in the province of literature.

Just at the time when Marx was still at the university the Young Hegelians took up the fight against the conservative section of Hegel’s disciples and the Christian Romanticism of Prussia. The antagonism between the old and the new school made itself felt both in religious philosophy and political literature, but both tendencies were seldom combined in the same persons. David Strauss subjected the Gospels to a candid criticism; Feuerbach investigated the nature of Christianity and of religion generally, and in this department inverted Hegel’s Idealism to Materialism; Bruno Bauer trained his heavy historical and philosophical artillery on the traditional dogmas concerning the rise of Christianity. Politically, however, they remained at the stage of the freedom of the individual: that is, they were merely moderate Liberals. Nevertheless, there were also less prominent Young Hegelians who were at that time in the Liberal left wing as regards their political opinions, such as Arnold Ruge.

None of the Young Hegelians had, however, used the dialectical method to develop still further the teaching of the Master. Karl Marx, the youngest of the Hegelians, first brought it to a higher stage in social science. He was no longer known to Hegel, who might otherwise have died with a more contented or perhaps even still more perturbed mind. Heinrich Heine, who

belonged to the Hegelians in the thirties and forties, relates the following anecdote, which if not true yet excellently illustrates the extraordinary difficulties of the Master's doctrines: —

As Hegel lay dying, his disciples, who had gathered [xxxii]round him, seeing the furrows deepen on the Master's care-worn countenance, inquired the cause of his grief, and tried to comfort him by reminding him of the large number of admiring disciples and followers he would leave behind. Breathing with difficulty, he replied: "None of my disciples has understood me; only Michelet has understood me, and," he added with a sigh, "even he has misunderstood me."

ENDNOTES.

¹ In one of the later chapters the reader will find the series of contradictions discovered by Marx in the evolution of capitalism. Sec. IV., "Outlines of the Economic Doctrine." Chapter 8, "Economic Contradictions."

² Marx, in "The Holy Family" (1844), reprinted by Mehring in the "Collected Works or Literary Remains of Marx and Engels," vol. II., p. 132.

³ After the death of Hegel differences of opinion arose among his disciples, chiefly with respect to his doctrines of the Deity, immortality and the personality of Christ. One section, the so-called "Right Wing," inclined to orthodoxy on these questions. In opposition to them stood the "Young Hegelians," the progressive "Left Wing." To this section belonged Arnold Ruge, Bruno Bauer, Feuerbach, and Strauss, author of the "Life of Jesus."

I. PARENTS AND FRIENDS.

I. Marx's Apprenticeship.

Karl Heinrich Marx first saw the light of day in Treves on May 5, 1818. His father, an enlightened, fine feeling, and philanthropic Jew, was a Jurist who had slowly risen from the humble circumstances of a German Rabbi family and acquired a respectable practice, but who never learnt the art of making money. His mother was a Dutchwoman, and came of a Rabbi family called Pressburg, which, as the name indicates, had emigrated from Pressburg, in Hungary, to Holland, in the seventeenth century. She spoke German very imperfectly. Marx has handed on to us one of her sayings, "If Karl made a lot of Capital, instead of writing a lot about Capital, it would have been much better." The Marxes had several children, of whom Karl alone showed special mental gifts.

In the year 1824 the family embraced Christianity. The baptism of Jews was at that time no longer a rarity. The enlightenment of the last half of the eighteenth century had undermined the dogmatic beliefs of many cultured Jews, and the succeeding period of German Christian Romanticism brought a strengthening and idealising of Christianity and of national feeling, from which, for practical just as much as for spiritual reasons, the Jews who had renounced their own religion could not escape. They were completely assimilated, felt and thought like the rest of their Christian and German fellow-citizens. Marx's father felt himself to be a good Prussian, and once recommended his son to compose an ode, in the grand style, on Napoleon's downfall and Prussia's victory. Karl did not, in truth, follow his father's advice, but from that time of Christian enthusiasm and German patriotic sentiment until his life's end, there remained with him an anti-Jewish prejudice; the Jew was generally to him either a usurer or a cadger.

Karl was sent to the grammar school in his native town, leaving with a highly creditable record. The school was, however, not the only place where he developed his mind. During his school years he used to frequent the house of the Government Privy Councillor, L. von Westphalen, a highly cultured Prussian official, whose favourite poets were Homer and Shakespeare, and who followed attentively the intellectual tendencies of his time. Although he had already reached advanced age, he liked to converse with the precocious youth, and to influence his mental growth. Marx

honoured him as a fatherly friend “who welcomes every progressive movement with the enthusiasm and sober judgment of a lover of truth, and who is a living proof that Idealism is no imagination, but the truth.” — (Dedication of Marx’s doctor thesis.)

After quitting the public school, Marx went to the University of Bonn, in order to study jurisprudence, according to his father’s wishes. After a year of the merry life of a student, he removed in the autumn of 1836 to Berlin University, the centre of culture and truth, as Hegel had called it in his Inaugural Lecture (1818). Before his departure for Berlin, he had become secretly engaged to Jenny Von Westphalen, the daughter of his fatherly friend, a woman distinguished alike for beauty, culture, and strength of character.

II. Student.

In Berlin, Marx threw himself into the study of Philosophy, Jurisprudence, History, Geography, Literature, the History of Art, etc. He had a Faust-like thirst for truth, and his appetite for work was insatiable; in these matters only superlatives can be used to describe, Marx. In one of his poems dating, from this period, he says of himself:

“Ne’er can I perform in calmness What has seized my soul with might,
But must strive and struggle onward In a ceaseless, restless flight.

All divine, enhancing graces Would I make of life a part; Penetrate the realms of science, Grasp the joys of Song and Art.”

Giving up all social intercourse, he worked night and day, making abstracts of what he read, translating from Greek and Latin, working at philosophical systems, setting down a considerable number of his own thoughts, and drafting outlines of philosophy or jurisprudence, as well as writing three volumes of poems. The year 1837 marks one of the critical periods of Marx’s intellectual development; it was a time of vacillation and ferment and of internal struggle, at the end of which he found refuge in the Hegelian dialectics. In so doing he turned his back on the abstract idealism of Kant and Fichte, and made the first step towards reality; and indeed at that time Marx firmly believed that Hegel actually stood for reality. In a somewhat lengthy letter dated November 10, 1837, a truly human document, Marx gives his father an account of his intense activity during

that remarkable period, comprising his first two terms at the University of Berlin, when he was still so very young:

“Dear Father,

“There are times which are landmarks in our lives; and they not only mark off a phase that has passed, but, at the same time, point out clearly our new direction. At such turning points we feel impelled to make a critical survey of the past and the present, so as to attain to a clear knowledge of our actual position. Nay, mankind itself, as all history shows, loves to indulge in this retrospection and contemplation, and thereby often appears to be going backward or standing still, when after all it has only thrown itself back in its armchair, the better to apprehend itself, to grasp its own doings, and to penetrate into the workings of the spirit.

“The individual, however, becomes lyrical at such times; for every metamorphosis is in part an elegy on the past and in part the prologue of a great new poem that is striving for permanent expression in a chaos of resplendent but fleeting colours. Be that as it may, we would fain set up a monument to our past experiences that they may regain in memory the significance which they have lost in the active affairs of life: and what more fitting way can we find of doing that than by bringing them and laying them before the hearts of our parents!

“And so now, when I take stock of the year which I have just spent here, and in so doing answer your very welcome letter from Ems, let me consider my position, in the same way as I look on life altogether, as the embodiment of a spiritual force that seeks expression in every direction: in science, in art, and in one’s own personality.... On my arrival in Berlin I broke off all my former connections, paid visits rarely and unwillingly, and sought to bury myself in science and art.... In accordance with my ideas at the time, poetry must of necessity be my first concern, or at least the most agreeable of my pursuits, and the one for which I most cared; but, as might be expected from my disposition and the whole trend of my development, it was purely idealistic. Next I had to study jurisprudence, and above all I felt a strong impulse to grapple with philosophy. Both studies, however, were so interwoven that on the one hand I worked through the Jurist’s Heineccius and Thibaut and the Sources docilely and quite uncritically, translating, for instance, the first two books of the Pandects of Justinian, while on the other hand I attempted to evolve a philosophy of law in the sphere of jurisprudence. By way of introduction I laid down a few metaphysical

principles, and carried this unfortunate work as far as Public Rights, in all about 300 sheets.

“In this, however, more than in anything else, the conflict between what is and what ought to be, which is peculiar to Idealism, made itself disagreeably prominent. In the first place there was what I had so graciously christened the Metaphysics of Law, i.e., first principles, reflections, definitions, standing aloof from all established jurisprudence and from every actual form of legal practice. Then the unscientific form of mathematical dogmatism in which there is so much beating about the bush, so much diffuse argumentation without any fruitful development or vital creation, hindered me from the outset from arriving at the Truth. A triangle may be constructed and reasoned about by the mathematician; it is a mere spatial concept and does not of itself undergo any further evolution; it must be brought in conjunction with something else, when it requires other properties, and thus by placing the same thing in various relationships we are enabled to deduce new relationships and new truths. Whereas in the concrete expression of the mental life as we have it in Law, in the State, in Nature, and in the whole of philosophy, the object of our study must be considered in its development.... The individual's reason must proceed with its self-contradiction until it discovers its own unity.”

In this we perceive the first trace of the Hegelian dialectic in Marx. We see rigid geometrical forms contrasted with the continually evolving organism, with social forms and human institutions. Marx had put up a stout resistance against the influence of the Hegelian philosophy; nay, he had even hated it and had made mighty efforts to cling faithfully to his idealism, but in the end he, too, must fall under the spell of the idea of evolution, in the form which it then assumed in Hegelian speculation in Germany.

Marx then goes on to speak of his legal studies as well as of his poems, and thus continues:

“As a result of these various activities I passed many sleepless nights during my first term, engaged in many battles, and had to endure much mental and physical excitement; and at the end of it all I found myself not very much better off, having in the meanwhile neglected nature, art and society, and spurned pleasure: such, indeed, was the comment which my body seemed to make. My doctor advised me to try the country, and so, having for the first time passed through the whole length of the city, I found myself before the gate on the Stralau Road.... From the idealism which I

had cherished so long I fell to seeking the ideal in reality itself. Whereas before the gods had dwelt above the earth, they had now become its very centre.

“I had read fragments of Hegel’s philosophy, the strange, rugged melody of which had not pleased me. Once again I wished to dive into the depths of the sea, this time with the resolute intention of finding a spiritual nature just as essential, concrete, and perfect as the physical, and instead of indulging in intellectual gymnastics, bringing up pure pearls into the sunlight.

“I wrote about 24 sheets of a dialogue entitled ‘Cleantes or on the Source and Inevitable Development of Philosophy.’ In this, art and science, which had hitherto been kept asunder, were to some extent blended, and bold adventurer that I was, I even set about the task of evolving a philosophical, dialectical exposition of the nature of the Deity as it is manifested in a pure concept, in religion, in nature, and in history. My last thesis was the beginning of the Hegelian system; and this work, in course of which I had to make some acquaintance with science, Schelling and history, and which had occasioned me an infinite amount of hard thinking, delivers me like a faithless siren into the hands of the enemy....

“Upset by Jenny’s illness and by the fruitlessness and utter failure of my intellectual labours, and torn with vexation at having to make into my idol a view which I had hated, I fell ill, as I have already told you in a previous letter. On my recovery I burnt all my poems and material for projected short stories in the vain belief that I could give all that up; and, to be sure, so far I have not given cause to gainsay it.

“During my illness I had made acquaintance with Hegel from beginning to end, as also with most of his disciples. Through frequent meetings with friends in Stralau I got an introduction into a Graduates’ Club, in which were a number of professors and Dr. Rutenberg, the closest of my Berlin friends. In the discussions that took place many conflicting views were put forward, and more and more securely did I get involved in the meshes of the new philosophy which I had sought to escape; but everything articulate in me was put to silence, a veritable ironical rage fell upon me, as well it might after so much negation.” — (“Neue Zeit,” 16th year, Vol. I., No. 1.)

His father was anything but pleased with this letter. He reproached Karl with the aimless and discursive way in which he worked. He had expected that these Berlin studies would lead to something more than breeding monstrosities and destroying them again. He believed that Karl would,

before everything else, have considered his future career, that he would have devoted all his attention to the lectures in his course, that he would have cultivated the acquaintance of people in authority, that he would have been economical, and that he would have avoided all philosophical extravagances. He refers him to the example of his fellow students who attend their lectures regularly and have an eye to their future:

“Indeed these young men sleep quite peacefully except when they now and then devote the whole or part of a night to pleasure, whereas my clever and gifted son Karl passes wretched sleepless nights, wearying body and mind with cheerless study, forbearing all pleasures with the sole object of applying himself to abstruse studies: but what he builds to-day he destroys again to-morrow, and in the end he finds that he has destroyed what he already had, without having gained anything from other people. At last the body begins to ail and the mind gets confused, whilst these ordinary folks steal along in easy marches, and attain their goal if not better at least more comfortably than those who condemn youthful pleasures and undermine their health in order to snatch at the ghost of erudition, which they could probably have exorcised more successfully in an hour spent in the society of competent men — with social enjoyment into the bargain!”

In spite of his unbounded love for his father, Marx could not deviate from the path which he had chosen. Those deeper natures who, after having lost their religious beliefs, have the good fortune to attain to a philosophical or scientific conception of the universe, do not easily shrink from a conflict between filial affection and loyalty to new convictions. Nor was Marx allured by the prospects of a distinguished official career. Indeed his fighting temperament would never have admitted of that. He wrote the lines:

Therefore let us, all things daring, Never from our task recede; Never sink in sullen silence, Paralysed in will and deed.

Let us not in base subjection Brood away our fearful life, When with deed and aspiration We might enter in the strife.

His stay in Stralau had the most beneficial effects on his health. He worked strenuously at his newly-acquired philosophical convictions, and for this his relations with the members of the Graduates' Club stood him in good stead, more especially his acquaintance with Bruno Bauer, a lecturer in theology, and Friedrich Köppen, a master in a grammar school, who in spite of difference of age and position treated him as an equal. Marx gave

up all thought of an official career, and looked forward to obtaining a lectureship in some university or other. His father reconciled himself to the new studies and strivings of his son; he was, however, not destined to rejoice at Karl's subsequent achievements. After a short illness he died in May, 1838, at the age of fifty-six.

Marx then gave up altogether the study of jurisprudence, and worked all the more assiduously at the perfecting of his philosophical knowledge, preparing himself for his degree examination in order — at the instigation of Bruno Bauer — to get himself admitted as quickly as possible as lecturer in philosophy at the University of Bonn. Bauer himself expected to be made Professor of Theology in Bonn after having served as lecturer in Berlin from 1834 to 1839 and in Bonn during the year 1840. Marx wrote a thesis on the Natural Philosophies of Democritus and Epicurus, and in 1841 the degree of Doctor of Philosophy was conferred on him at Jena. He then went over to his friend Bauer in Bonn, where he thought to begin his career as lecturer. Meanwhile his hopes had disappeared. Prussian universities were at that time no places for free inquirers. It was not even possible for Bauer to obtain a professorship; still less could Marx, who was much more violent in the expression of his opinions, reckon on an academic career. His only way out of this blind alley was free-lance journalism, and for this an opportunity soon presented itself.

III. Beginnings of Public Life.

Marx made his entry into public life with a thorough philosophical training and with an irrestrainable impulse to enter into the struggle for the spiritual freedom of Germany. By spiritual freedom he understood first and foremost freedom in religion and liberalism in politics. He was, too, perfectly clear as to the instrument to be used: it was criticism. The positive and rigid having become ineffectual and unreasonable, is to fall before the weapon of criticism and so make room for a living stream of thought and being, or as Marx himself expressed it in 1844, "to make the petrified conditions dance by singing to them their own tune." Their own tune is, of course, the dialectic. Criticism, generally speaking, was the weapon of the Young Hegelians. Criticism is negation, sweeping away existing conditions and prevailing dogmas to make a clear path for life. Not the setting up of new

principles or new dogmas, but the clearing away of the old dogmas is the task of the Young Hegelians. For if dialectic be rightly understood, criticism or negation is the best positive work. Criticism finds expression, above all, in polemics, in the literal meaning of waging war — ruthless war — against the unreal for the purpose of shaking up one's contemporaries.

After Marx had given up all hope of an academic career, the only field of labour that remained open to him was, as we have already said, that of journalism. His material circumstances compelled him, moreover, to consider the question of an independent livelihood. Just about this time the Liberals in the Rhine provinces took up a scheme for the foundation of a newspaper, the object of which was to prepare the way for conditions of greater freedom. The necessary money was soon procured. Significantly enough, Young Hegelians were kept in view for editors and contributors. On the first of January, 1842, the first number of the *Rheinische Zeitung* was published at Cologne. The editor was Dr. Rutenberg, who had formed an intimate friendship with Marx at the time the latter was attending the University of Berlin; and so Marx, then in Bonn, was also invited to contribute. He accepted the invitation, and his essays brought him to the notice of Arnold Ruge, who likewise invited him to take part in his literary undertakings in conjunction with Feuerbach, Bauer, Moses Hess, and others. Marx's essays were greatly appreciated, too, by the readers of the *Rheinische Zeitung*, so that in October, 1842, on the retirement of Rutenberg, he was called to the editorial chair of that journal. In his new position he had to deal with a series of economic and political questions which, no doubt, with a less conscientious editor would have occasioned little hard thinking, but which for Marx showed the need of a thorough study of political economy and Socialism. In October, 1842, a congress of French and German intellectuals was held in Strasburg, and amongst other things French Socialist theories were discussed. Likewise in the Rhine provinces arose questions concerning landed property and taxes, which had to be dealt with from the editorial chair, questions which were not to be answered by a purely philosophical knowledge. Besides, the censorship made the way hard for a paper conducted with such critical acumen, and did not allow the editor to fulfil his real mission. In the preface to "The Critique of Political Economy" (1859) Marx gives a short sketch of his editorial life:

"As editor of the *Rheinische Zeitung*, in 1842 and 1843 I came up, for the first time, against the difficulty of having to take part in the controversy

over so-called material interests. The proceedings of the Diet of the Rhine provinces with regard to wood stealing and parcelling out of landed property, and their action towards the farmers of the Moselle districts, and lastly debates on Free Trade and Protection, gave the first stimulus to my investigation of economic questions. On the other hand, an echo of French Socialism and Communism, feebly philosophical in tone, had at that time made itself heard in the columns of the *Rheinische Zeitung*. I declared myself against superficiality, confessing, however, at the same time that the studies I had made so far did not allow me to venture any judgment of my own on the significance of the French tendencies. I readily took advantage of the illusion cherished by the directors of the *Rheinische Zeitung*, who believed they could reverse the death sentence passed on that journal as a result of weak management, in order to withdraw from the public platform into my study.”

And so the intellectual need which he felt of studying economics and Socialism, as well as his thirst for free, unfettered activity, resulted in Marx’s retirement from his post as editor, although he was about to enter upon married life and had to make provision for his own household. But he was from the beginning determined to subordinate his material existence to his spiritual aspirations.

II. THE FORMATIVE PERIOD OF MARXISM.

I. The Franco-German Year Books.

Between the years 1843 and 1844 we have the second and probably the most important critical period in the intellectual development of Marx. In 1837 he had become a disciple of Hegel, into whose philosophy he penetrated deeper and deeper during the two years which ensued. Between 1843 and 1844 he became a Socialist, and in the following two years he laid the foundations of those social and historical doctrines associated with his name. Of the way he came to be a Socialist and by what studies he was led to Socialism, we know nothing. All that can be said is that in the summer of 1848 he must have pursued the reading of French Socialist literature just as assiduously as he did the study of Hegel in 1837. In his letters to Arnold Ruge, written about 1843, and printed in the Franco-German Year Books, we find a few passages which bear witness to his sudden turnover. In a letter from Cologne (May, 1843) he remarks: "This system of acquisition and commercialism, of possession and of the exploitation of mankind, is leading even more swiftly than the increase of population to a breach within the present society, which the old system cannot heal, because indeed it has not the power either to heal or create, but only to exist and enjoy."

That is still in the sentimental vein, and anything but dialectical criticism. In the following few months, however, he made surprisingly rapid progress towards the fundamental ideas of that conception of history and society, which later on came to be known as Marxism, and which he almost built up into a complete system during those restless years of exuberant creative activity, 1845-46. In a letter from Kreuznach, dated September, 1843, he shows already an acquaintance with Fourier, Proudhon, Cabet, Weitling, etc., and sees his task not in the setting up of Utopias but in the criticism of political and social conditions, "in interpreting the struggles and aspirations of the age." And by the winter of 1843 he has already advanced so much as to be able to write the introduction to the criticism of Hegel's "Philosophy of Law," which is one of the boldest and most brilliant of his essays. He deals with the question of a German revolution, and asks which is the class that could bring about the liberation of Germany. His answer is that the positive conditions for the German revolution and liberation are to

be sought “in the formation of a class in chains, a class which finds itself in bourgeois society, but which is not of it, of an order which shall break up all orders. The product of this dissolution of society reduced to a special order is the proletariat. The proletariat arises in Germany only with the beginning of the industrial movement; for it is not poverty resulting from natural circumstances but poverty artificially created, not the masses who are held down by the weight of the social system but the multitude arising from the acute break-up of society — especially of the middle class — which gives rise to the proletariat. When the proletariat proclaims the dissolution of the existing order of things, it is merely announcing the secret of its own existence, for it is in itself the virtual dissolution of this order of things. When the proletariat desires the negation of private property, it is merely elevating to a general principle of society what it already involuntarily embodies in itself as the negative product of society.”

Marx wrote this in Paris, whither he had removed with his young wife in October, 1843, in order to take up the editorship of the Franco-German Year Books founded by Arnold Ruge. In a letter addressed to Ruge from Kreuznach in September, 1843, Marx summed up the program of this periodical as follows: “If the shaping of the future and its final reconstruction is not our business, yet it is all the more evident what we have to accomplish with our joint efforts, I mean the fearless criticism of all existing institutions — fearless in the sense that it does not flinch either from its logical consequences or from the conflict with the powers that be. I am therefore not with those who would have us set up the standard of dogmatism; far from it; we should rather try to give what help we can to those who are involved in dogma, so that they may realise the implications of their own principles. So, for example, Communism as taught by Cabet, Dezamy, Weitling, and others is a dogmatic abstraction.... Moreover, we want to work upon our contemporaries, and particularly on our German contemporaries. The question is: How is that to be done? Two factors cannot be ignored. In the first place religion, in the second place politics, are the two things which claim most attention in the Germany of to-day.... As far as everyday life is concerned, the political State, even where it has not been consciously perfected through Socialist demands, exactly fulfils, in all its modern forms, the demands of reason. Nor does it stop there. It presupposes reason everywhere as having been realised. But in so doing it lands itself everywhere in the contradiction between its ideal purpose and

its real achievements. Out of this conflict, therefore, of the political State with itself social truth is evolved.”

Without a doubt, the Hegelian conception of the State as the embodiment of reason and morality did not accord well with the constitution and the working of the actual State. And Marx goes on to remark that in its history the political State is the expression of the struggles, the needs, and the realities of society. It is not true, then, as the French and English Utopians have thought, that the treatment of political questions is beneath the dignity of Socialists. Rather is it work of this kind which leads into party conflict and away from the abstract theory. “We do not then proclaim to the world in doctrinaire fashion any new principle: ‘This is the truth, bow down before it!’ We do not say: ‘Refrain from strife, it is foolishness!’ We only make clear to men for what they are really struggling, and to the consciousness of this they must come whether they will or not.”

That is conceived in a thoroughly dialectical vein. The thinker propounds no fresh problems, brings forward no abstract dogmas, but awakens an understanding for the growth of the future out of the past, inspiring the political and social warriors with the consciousness of their own action.

II. Friendship with Friedrich Engels.

Of the Franco-German Year Books only one number appeared (Spring, 1844). Alongside Marx’s contributions (an Introduction to the criticism of Hegel’s “Philosophy of Jurisprudence” and a review of Bauer’s book on the Jewish Question) the volume contains a comprehensive treatise, “Outlines for a Criticism of Political Economy,” from the pen of Friedrich Engels (born in Barmen, 1820; died in London, 1895), who was then living in Manchester. In September, 1844, Engels went to visit Marx in Paris. This visit was the beginning of the lifelong intimate friendship between the two men, who without a close collaboration would not have achieved what they did.

Marx was a highly-gifted theorist, a master in the realm of thought, but he was quite unpractical in the affairs of everyday life. Had he enjoyed a regular income throughout life, he would probably have attained his end even without the help of Engels. On the other hand, Engels was an exceedingly able, energetic, and highly-cultured man, eminently practical

and successful in everything he undertook, but not endowed with that speculative temperament which surmounts intellectual crises and opens out new horizons. But for his intellectual association with Marx he would, in all probability, have remained little more than a Moses Hess. Marx was never a Utopian; the complete saturation of his mind with Hegelian dialectics made him immune to all eternal truths and final social forms. On the contrary, up to 1844 Engels was a Utopian — until Marx explained to him the meaning of political and social conflicts, the basis and the motive force, the statics and dynamics of the history of civilised mankind. Engels' "Criticism of Political Economy" is a very noteworthy performance for a youth of twenty-three engaged in commerce, but it does not rise above the level of the writings of Owen, Fourier, and Proudhon. Engels' contributions to Owen's "New Moral World" (1843-44) are indeed more philosophical than the other articles by Owenites, but as far as matter goes, there is no perceptible difference between them. "The System of Economic Contradictions," on which Proudhon was working when Engels published his "Outlines," is couched, as far as the critical side is concerned, in the same strain of thought as we find in Engels. Both sought to expose the contradictions of the middle-class economic system, not in order to discover in them the source of the progress of society, but to condemn them in the name of justice. Whereas the Owenites considered their system as perfect, Proudhon and Engels had, independently of one another, striven to free themselves from the Socialist Utopias. Proudhon became a peaceful Anarchist and found salvation in the scheme of autonomous economic groups, which should carry on an exchange of labour equivalents with one another. Engels, on the other hand, found a solution of his difficulties in Marx, whom he rewarded with a lifelong friendship and devotion, which proved to be Marx's salvation. Without Engels' literary and financial help, Marx, with his unpractical, helpless, and, at the same time, proud and uncompromising disposition, would most probably have perished in exile.

III. Controversies with Bauer and Ruge.

After the Franco-German Year Books had been discontinued, Marx, recognising the importance of economics, studied English and French systems of political economy with still greater zeal than before, and

continued his studies in Socialism and history with remarkable steadiness of purpose. No longer now did he show signs of hesitation or wavering; he knew exactly what he wanted. He had left behind him that period of ideological speculation when he was still a disciple of Hegel, and he was impelled, as in the autumn of 1837, to envisage, from his new standpoint, the past and the future. He takes such a survey in "The Holy Family," which had its genesis in the autumn of 1844, and to which Engels also furnished a slight contribution. It is a settling of accounts with his former friend and master, Bruno Bauer, and his brother Edgar, who had not been able to break away from Hegel. The aim of the book was to force the Young Hegelians into the path of social criticism, to urge them forward and prevent them from falling into stereotyped and abstract ways of thinking. It is not easy reading. In it Marx has compressed the knowledge he then had of philosophy, history, economics, and Socialism in concentrated and sharply-cut form. Besides the excellent sketch of English and French materialism, which among other things discloses in a few short but pregnant sentences the connection between this and English and French Socialism, "The Holy Family" contains the germs of the materialistic conception of history as well as the first attempt to give a social revolutionary interpretation to the class struggle between Capital and Labour. In the Introduction to the present book a quotation from "The Holy Family" has been given. Speaking against Bauer's conception of history, Marx says: "Or can he believe that he has arrived even at the beginning of a knowledge of historical reality so long as he excludes science and industry from the historical movements? Or does he really think that he can understand any period without having studied, for example, the industries of that period, the immediate means of production of life itself?... In the same way as he separated thought from the senses, the soul from the body, and himself from the world, so he separates history from science and industry, and he does not see the birthplace of history in coarse, material production upon earth but in the nebulous constructions in the heavens." — ("Posthumous Works," Vol. II., pp. 259-60.)

Bruno Bauer, who believed in the world-swaying might of the idea, but would not concede that the masses had any power whatever, wrote: "All the great movements of history up to this time were therefore doomed to failure and could not have lasting success, because the masses had taken an interest in them and inspired them — or they must come to a lamentable conclusion

because the underlying idea was of such a nature that a superficial apprehension of it must suffice, that is to say, it must reckon on the approval of the masses.”

Marx’s answer to this was that “the great historical movements had been always determined by mass interests, and only in so far as they represented these interests could the ideas prevail in these movements; otherwise the ideas might indeed stir up enthusiasm, but they could not achieve any results. The idea always fell into disrepute in so far as it differed from the interest. On the other hand, it is easy to understand that, when it makes its first appearance on the world-stage, every mass interest working itself out in history far exceeds, as an idea or in its presentation, its actual limits and identifies itself purely and simply with the interest of humanity. Thus the idea of the French Revolution not only took hold of the middle classes, in whose interest it manifested itself in great movements, but it also aroused enthusiasm in the labouring masses, for whose conditions of existence it could do nothing. As history has shown, then, ideas have only had effective results in so far as they corresponded to class interests. The enthusiasm, to which such ideas gave birth, arose from the illusion that these ideas signified the liberation of mankind in general.” — (“Posthumous Works,” Vol. II., pp. 181-3.)

In August, 1844, Marx published under the title “Marginal Notes” in the Paris *Vorwärts* a lengthy polemic against Ruge, which is a defence of Socialism and revolution and takes the part of the German proletariat against Ruge. “As regards the stage of culture or the capacity for culture of the German workers, let me refer to Weitling’s clever writings, which in their theoretical aspect often surpass those of Proudhon, however much they may fall behind them in execution. Where would the middle classes, their scholars and philosophers included, be able to show a work like Weitling’s ‘Guarantees of Peace and Concord’ bearing on the question of emancipation? If one compares the insipid, spiritless mediocrity of German political literature with this unconstrained and brilliant literary début of the German workers, if one compares these gigantic baby shoes of the proletariat with the dwarfishness of the worn-out political shoes of the German middle classes, one can only prophesy an athletic stature for the German Cinderella. One must admit that the German proletariat is the philosopher of the European proletariat, just as the English proletariat is its political economist and the French proletariat its politician. One must admit

that Germany is destined to play just as classic a rôle in the social revolution as it is incompetent to play one in the political. For, as the impotence of the German middle classes is the political impotence of Germany, so the capacity of the German proletariat — even leaving out of account German philosophy — is the social capacity of Germany.”

At that time (1844) Marx had already begun to mix among the German working classes resident in Paris, who clung to the various Socialist and Anarchist doctrines which then held sway, and he sought to influence them according to his own ideas. With Heine, too, who at that time was coquetting with Communism, he carried on a sprightly and not unfruitful intercourse. He likewise came into frequent contact with Proudhon, whom he endeavoured to make familiar with Hegelian philosophy. Already in his first work, “What is Property?” (1840) Proudhon had played with Hegelian formulæ, and Marx probably believed that he could win him over to Socialism. Proudhon, who, like the German Weitling, sprang from the proletariat, ushered in his activity as a social theorist with the above-mentioned work, which had a stimulating effect on Marx and on German Socialists in general, all the more so as Proudhon manifested some acquaintance with classical German philosophy. In this book (“What is Property?” German edition, 1844, p. 289) he sums up the whole matter as follows: “Expressing this according to the Hegelian formula, I should say that Communism, the first kind, the first determination of social life, is the first link in social evolution, the *thesis*; property is the antagonistic principle, the *antithesis*; if only we can get the third factor, the *synthesis*, the question is solved. This synthesis comes about only through the cancelling of the thesis by the antithesis; one must therefore in the last instance examine its characteristics, discard what is anti-social, and in the union of the remaining two is then seen the real kind of human social life.”

That was indeed a superficial conception of Hegelian dialectics, for what Proudhon wanted to find was not a synthesis but a combination; still for a French working man it was a smart performance to have manipulated German philosophical formulæ, and would justify the most sanguine hopes. Marx did not want to let this opportunity slip, and in “debates both late and long” he discussed Hegelian philosophy with Proudhon. — (Marx: “The Poverty of Philosophy,” German edition, Stuttgart, 1885, p. 29.)

In the midst of this activity, however, Marx and other German contributors to the Paris *Vorwärts* were expelled from France in January,

1845, at the instigation of the Prussian Government. Marx packed up his traps and left for Brussels, where he lived, with short interruptions, until the outbreak of the European Revolution in February, 1848. During his sojourn in Brussels his time was occupied mainly with economic studies, for which Engels placed his library of works on political economy at his disposal. Marx embodied the result of these studies in the criticism directed against Proudhon in his “*Misère de la Philosophie*” (Poverty of Philosophy), published in 1847.

IV. Controversy with Proudhon.

Marx’s “*Misère de la Philosophie*” indicates the culmination of the first phase of his creative work. In this critical review he makes his position clear with respect not only to Proudhon but to Utopian Socialism in general. It marks also the turning point in the studies of Marx: English political economy occupied henceforth the place which German philosophy had held. The anti-Proudhon controversy is therefore worthy of a fuller treatment.

Pierre Joseph Proudhon (b. 1809 in Besançon, d. 1865 in Paris) was one of the most gifted and most distinguished of social philosophers which the modern proletariat has produced. He was originally a compositor, like his similarly minded English contemporary, John Francis Bray, the author of “*Labour’s Wrongs*,” published in 1839, but he had a much greater inclination for study and a more fruitful literary talent. He managed to acquire, self-taught, a knowledge of the classical languages, of mathematics and of science, read assiduously but indiscriminately works on economics, philosophy, and history, and applied himself to social criticism. It is rare for a working man in the West of Europe to feel impelled to make an acquaintance with Kant, Hegel, and Feuerbach as Proudhon did through French translations and through intercourse with German scholars in Paris. He possessed the noble ambition of blending French sprightliness with German thoroughness. But self-instruction failed to give him that intellectual training which is more valuable than knowledge, and which alone gives the power to order and to utilise the information acquired, as well as to submit one’s own work to self-criticism. The value of a systematic education does not consist in the main in the acquisition of

knowledge but in the training of our intellectual faculties as instruments of inquiry and apprehension, of methodical thinking and of sound judgment, to enable us to find our bearings more easily in the chaos of phenomena, experiences, and ideas. A self-taught man may no doubt attain to this degree of culture, but only if his first attempts at independent creative work are submitted to a strict but kindly criticism, which makes him discipline his thoughts. This was not the case with Proudhon; he lacked mental self-discipline. His first work, "What is Property?" (1840) brought him immediate recognition and strengthened him in his high opinion of his knowledge and his powers, even to the point of making him conceited. When, for example, the French historian, Michelet, disapproved of his dictum, "Property is robbery," Proudhon replied, "Not twice in a thousand years does one come across a pronouncement like that." — ("Economic Contradictions," Leipzig, 1847. Vol. II., p. 301.) And yet the idea is as old as Communism itself. Besides all this, the vivacity and exuberance of language for which Proudhon was noted easily blinded him to the shortcomings of his intellectual culture. Thus it often happened that he rediscovered ideas of his predecessors and published them to the world with naïve pride. Through page after page of argument he holds the reader in expectation of the explanation, which he is about to give, of the nature of value, which he rightly characterises as the "corner-stone of political economy." At last he will disclose the secret: "It is time to make ourselves acquainted with this power. This power ... is *labour*." His main work, "The System of Economic Contradictions," swarms with philosophical formulæ and expressions like thesis, antithesis, antinomies, synthesis, dialectics, induction, syllogisms, etc., as also with Latin, Greek, and Hebrew etymologies; it often wanders into irrelevant theological and philosophical digressions and side issues, not so much with the intention of parading the author's knowledge as from his lack of intellectual discipline and insufficient command of his material. The work in question was to combine German philosophy with French and English political economy, and its author believed that it would secure for him before everything else the admiration of the German Socialists, especially of Marx. He drew the latter's attention to it by letter, and awaited his "rigorous criticism." The criticism came in "Misère de la Philosophie" (Brussels, 1847), but it could no longer fulfil its purpose, as the fundamental difference between the two men had already widened to a gulf that could not be bridged. Marx had

almost completed his materialistic, logical, and revolutionary Socialism, Proudhon had laid the foundations of his peaceful Anarchism with its federative economic basis. With his searching analysis, his systematised knowledge, and his great indignation at the presumptuous attacks on every Socialist school and leader, Marx sat in judgment upon Proudhon, exposing him as a dilettante in philosophy and economics, and at the same time sketching in outline his own conception of history and economics.

Marx's verdict is damning, yet one cannot but acknowledge that Proudhon, in spite of his obvious insufficiency, had endeavoured, honestly and zealously, to extricate himself from Capitalism as well as from Utopianism, and to outline a scheme for an economic order, in which men, such as he had found them, might lead a free, industrious, and righteous life. The task which Proudhon had set himself was the same as that which engaged the attention of Marx, the criticism of political economy and of the sentimental Utopian Socialism. That is the key-note of Proudhon's system, and it is sounded in almost every chapter. He lacked, however, the requisite knowledge and the historical sense which alone could have made him equal to his task. The whole of his criticism consists virtually in the complaint that riches and poverty accumulate side by side, and that the economic categories — use value, exchange value, division of labour, competition, monopoly, machinery, property, ground rent, credit, tax, etc. — manifest contradictions. Proudhon's special problem was the following: "The workers of any country produce yearly goods to the value, let us say, of 20 milliards. But if the workers, as consumers, wish to buy back these goods they have to pay 25 milliards. The workers are thus cheated out of a fifth. That is a terrible contradiction." — ("What is Property?" Chap. IV.; "Economic Contradictions," Vol. I., pp. 292-93.) This statement of the problem shows that Proudhon had no inkling of the essential features of the question of value, in spite of the fact that he cites Adam Smith, David Ricardo, etc., whom he must therefore have read. Had he really understood these economists and taken up his critical attitude towards them from the standpoint of justice, he would have stated the problem somewhat as follows: "The workers of any country produce yearly goods to the value, say, of 20 milliards. For their work, however, they receive as wages a quantity of goods of the value of only 10 or 12 milliards. Is that just?" Only this way of stating the question could possibly have revealed to him the nature of wages, of value, of profit, of capital and its contradictions.

Proudhon sees the perpetration of fraud or robbery in the sphere of exchange and not in that of production, and he does not ask himself how, if labour produces goods to the value of only 20 milliards, they can be exchanged at a value of 25 milliards, and what is responsible for the increase of five milliards. The other contradictions which he brings forward are not indeed new, but they are ingeniously treated. For example: the essence of exchange-value is labour, which creates wealth; but the more the wealth produced, the less becomes its exchange-value. Or this: the division of labour is, according to Smith, one of the most effective means of increasing wealth, but the further the division of labour proceeds the lower sinks the workman, being reduced to the level of an unintelligent automaton engaged in the performance of a fractional operation. The same thing holds good for machinery. So, too, competition stimulates effort, but brings much misery in its train by leading to adulteration, sharp practices, and strife between man and man. Further, taxation should be proportional to riches, in reality it is proportional to poverty. Or again, private ownership of land ought to increase productivity; in practice it deprives the farmer of the land. In this way he runs to earth the contradictions in political economy, and so we find everywhere the words thesis and anti-thesis or antinomies (contradictions between two well-established propositions). And out of this contradiction springs poverty. The solution or the synthesis is the creation of an economic order which shall preserve the good elements in this category and eliminate the bad ones, and so satisfy the demands of justice. And that is what Socialism cannot do. "For the economic order is based upon calculations of an inexorable justice and not upon those angelic sentiments of brotherhood, sacrifice, and love which so many well-meaning Socialists of the present time are endeavouring to awake in the people. It is useless for them to preach, after the example of Jesus Christ, the necessity for sacrifice, and to set an example of it in their own lives: selfishness is stronger than they and can only be restrained by rigid justice and immutable economic law. Humanitarian enthusiasm may cause upheavals which are conducive to the progress of civilisation, but such emotional crises, like the fluctuations in value, simply result in the establishing of law and order on a more rigid and more restricted basis. Nature or the Deity planted mistrust in our hearts, having no faith in the love of man for his fellow men; and though I say it to the shame of the human conscience (for our hypocrisy must be confronted with it sooner or later), every disclosure which science

has made to us concerning the designs of providence with respect to the progress of society points to a deeply rooted hatred of mankind on God's part." — ("System of Economic Contradictions or the Philosophy of Poverty," Vol. I., p. 107.) Just as severely does he denounce the institution of Trade Unionism and its methods of warfare, together with State politics, as indeed the working of class organisation and of the State generally. The only way to realise social justice is to create a society of producers who exchange their goods among one another according to their equivalents in labour and carry on work in adequate relationship to the production of wealth, or, to put it clearly, to establish an order where supply and demand balance one another.

Marx's answer to the "Philosophy of Poverty" is indicated at once by the title "The Poverty of Philosophy." He deals first of all with the economic details of Proudhon's work, and proves with documentary evidence that the theses and antitheses it contains partly spring from a half-understood reading of English and French political economists, and in part have been taken direct from the English Communists. Marx already displays in this section an extensive knowledge of economic literature. Then he confronts Proudhon's philosophical and social theories with his own deductions and gives many positive results. Marx's main object was to induce the Socialists to give up their Utopianism and think in terms of realism, and to regard social and economic *categories* in their historical setting:

"Economic *categories* are only the theoretical expressions, ideal conceptions of the conditions of production obtaining in society.... Proudhon has grasped well enough that men manufacture cloth, linen, etc., under certain conditions of production. But what he has not grasped is that these social conditions themselves are just as much human products as cloth, linen, etc. Social conditions are intimately bound up with productive power. With the acquisition of new productive power men change their methods of production, and with the change in the methods of production, in the manner of obtaining a livelihood, they change their social conditions. The hand-mill gives rise to a society with feudal lords, the steam-mill to a society with industrial capitalists. But the same men who shape the social conditions in conformity with the material means of production, shape also the principles, the ideas, the *categories* in conformity with their social conditions. Consequently these ideas, these *categories*, are just as little eternal as are the conditions to which they give expression. They are the

transitory and changing products of history. We are living in the midst of a continuous movement of growth in productive power, of destruction of existing social conditions, of formation of ideas.” — (“Poverty of Philosophy,” Stuttgart, 1885, pp. 100-101.)

Here it should, above all, be noticed that Marx ascribes to industrialism a powerful revolutionary effect, and that he characterises the different forms of society by their different methods of labour. Or, as he says later in “Capital,” “not *what* is produced, but *how* it is produced distinguishes the various forms of society.” What he means to say, then, is that ideas and systems are limited by their time, that they are conditioned by the prevailing means of production. To understand them one must study the times which have preceded them, as well as investigate the ideas and systems themselves, and find out whether new forms have not arisen which stand in contradiction or in contrast to the old one. Or, as Marx says:

“Feudalism, too, had its proletariat — the villeinage — which contains all the germs of the middle class. Feudal production, too, had two contradictory elements which are likewise characterised as the ‘good’ and ‘bad’ sides of feudalism without regard to the fact that it is always the ‘bad’ side which triumphs ultimately over the ‘good’ side. It is the bad side which calls into being the movement which makes history, in that it brings the struggle to a head. If, at the time of the supremacy of feudalism, the economists, in their enthusiasm for knightly virtues, for the beautiful harmony between rights and duties, for the patriarchal life of the towns, for the flourishing home industries in the country, for the development of industry organised in corporations, companies and guilds, in a word, for everything which forms the finer side of feudalism, had set themselves the problem of eliminating everything which could throw a shadow on this picture — serfdom, privileges, anarchy — where would it all have ended? They would have destroyed every element which called forth strife, they would have nipped in the bud the development of the middle class. They would have set themselves the absurd problem of blotting out history.

“When the middle class had come to the top, neither the good nor the bad side of feudalism come into question. The productive forces, which had been developed under feudalism through its agency, fell to its control. All old economic forms, the legal relations between private individuals, which corresponded to them, the political order, which was the official expression of the old society, were shattered.”

“Those Socialists and social revolutionaries who regard the hardships and struggles of society as an absolute evil and plan the construction of a society comprised solely of good elements, have not grasped the meaning of the history of mankind. They think abstractly. They misjudge both the past and the present.

“Hence to form a correct judgment of production under feudalism one must consider it a method of production based upon contradiction. One must show how wealth was produced within this contradiction, how productive power developed contemporaneously with the antagonism of classes, how one of these classes, the bad side, the social evil, constantly increased until the material conditions for its liberation were fully ripe.

“Does that not show clearly enough that the means of production, the conditions under which productive power is developed, are anything but eternal laws, that they rather correspond to a definite stage in the evolution of mankind and of its productive power, and that a variation in the productive power of mankind necessarily brings about a variation in its conditions of production?

“The middle class begins with a proletariat, which in its turn is itself a remnant of the feudal proletariat. In the course of its historical development the middle class necessarily develops its contradictory character, which on its first appearance is more or less veiled, existing only in a latent form. In proportion as the middle class develops, there develops in its bosom a new proletariat, a modern proletariat; and a struggle arises between the proletarian class and the middle class, a struggle which, before being felt, observed, estimated, understood, acknowledged, and finally openly proclaimed on both sides, issues in the meanwhile only in partial and transitory conflicts and acts of destruction.”

In a special chapter Marx shows the necessity and the historical significance of the Trade Unions, which in spite of all the apprehensions and warnings of Utopians and Economists the workers have gone on establishing and perfecting, in order to be able to withstand the domination of capital. That means the gathering together of the divided interests and activities of the workers in a vast class movement, standing in opposition to the middle class; which, however, does not exclude the possibility of conflicting interests within the classes themselves, though these shall be put aside as soon as class is brought against class:

“From day to day it becomes clearer then that the conditions of production, among which the middle class moves, have not a simple, uniform character but one which involves conflicting elements; that the same conditions which produce wealth produce also poverty; that the same conditions which tend to the development of productive power develop also the power of repression; that these conditions only create bourgeois wealth, i.e., the wealth of the middle class, at the cost of the continued destruction of the wealth of individual members of this class and the creation of an ever-increasing proletariat.” — (“Poverty of Philosophy,” 1885, pp. 116-118, 177 sq.)

This antithetical character of capitalist society has for its effect that the political economists, who are the philosophers of the existing order, lose their bearings, while the Socialists, who are the philosophers of the proletariat, look round for means to relieve the distress. They condemn class struggles,⁴ build Utopias and plan schemes of salvation, whereas the only real solution, because it is the only one which arises from the actual conditions, must be to further the organisation of the oppressed class and make it conscious of the objects of its struggles. For out of these struggles the new society will arise, and that, of course, can only happen when productive power has reached a high stage of development. Or as Marx himself proceeds:

“An oppressed class is a vital condition of any society founded upon class antagonism. The liberation of the oppressed class necessarily includes, therefore, the creation of a new society. In order that the oppressed class may be able to free itself, a stage must be reached in which the already acquired powers of production and the prevailing social institutions can no longer exist side by side. Of all the instruments of production, the greatest productive force is the revolutionary class itself. The organisation of the revolutionary elements as a class presupposes the existence in perfected form of all the productive forces that could in any way be developed in the bosom of the old society. Does this mean that after the collapse of the old order of society there will be a new class domination culminating in a new political power? The condition of the emancipation of the working class is the abolition of all classes, as the condition of the emancipation of the third estate, of the middle class, was the abolition of all the three estates. The working class will, in the course of its evolution, replace the old middle-class society by an association excluding classes and their antagonism, and

there will no longer be any real political power,⁵ because it is just this political power which is the official expression of class antagonism within the community.

“Meanwhile the antagonism between proletariat and bourgeoisie is a struggle of class against class, a struggle which, when brought to its highest expression, means a complete revolution. And can one indeed be surprised that a society founded upon class antagonism should, at its final dissolution, issue in brutal conflict and collision of man against man? Let it not be said that the social movement excludes the political. There never was a political movement which was not at the same time a social movement.

“Only in an order of things where there are no classes and no class antagonism will social evolution cease to be political revolution. Until then the last word of social science on the eve of every general reconstruction of society must ever be: ‘Fight or die; bloody war or annihilation. Thus are we confronted with the inexorable question.’ — (George Sand).”

With this battle-cry “The Poverty of Philosophy” comes to a close. It is the prologue to the “Communist Manifesto,” which in itself is but a popular version of the positive doctrines developed in the controversy against Proudhon.

ENDNOTES.

⁴ The Socialists of those times were the Owenites and the Fourierists, who condemned all class struggles, Trade Unionist strikes, and Labour politics.

⁵ Marx means the State.

III. YEARS OF AGITATION AND VARYING FORTUNES.

I. The Revolutionary Spirit of the Forties.

Marx was a revolutionary not only in the sense that he was the representative of a new conception of society and the founder of a theory of a new economic order, but also in the popular sense of advocating the use of force, in which connection he looked to the first years of the French Revolution as a model. He had a keen ear for the revolutionary rumblings in the depths of the populace. The years during which the elements of his new conception of society were accumulating in his mind and shaping themselves into a system were involved in a revolutionary atmosphere. In 1842 England witnessed the first strike on a large scale, which threatened to extend into a general strike and bore a political revolutionary character. In 1843 and 1844 the idea of the impending revolution was widely spread in England. Insurrections broke out among the Silesian weavers in 1844. In 1845 and 1846 Socialism spread rapidly on all sides in Germany, and Socialist periodicals appeared in the industrial centres. France swarmed with Socialist systems, Socialist novels and newspaper articles. The spectre of Communism was abroad in Europe. The convention of the United Assembly by Frederick William IV. at the beginning of February, 1847, was looked upon as the harbinger of the German Revolution. The connection between these phenomena could not escape acute intellects. Hand in hand with the extension of industry and the rapid construction of railways and telegraphs came alternations of economic prosperity and crisis, poverty grew, and the workers fought with ever-increasing bitterness against the iron law of wages and against the scanty pay, which hardly allowed the proletariat to eke out a bare subsistence. The cry in England was: "More factories, more poverty," but at the same time: "The greater the political rights of the masses, the surer becomes emancipation." Whoever lived in England and France during these years and had dealings with Socialism could not help feeling that political and social revolutions were on the march.

Already in his first letter to Ruge, written from Holland in March, 1843, Marx deals with the coming revolution, and foresees, to the astonishment of

Ruge, who refused to believe it, that the Government of Frederick William IV. was drifting towards a revolution. At that time Marx had hardly begun his studies in Socialism; and the further he advanced in these studies, elaborating his social dialectics and evolving the ideas of the class struggle, the more inevitably was he driven to the conclusion that the proletarian revolution, the seizure of political power by the proletariat, was the indispensable preliminary to the triumph of Communism.

Utopian Socialism stood outside the State and attempted to set up a Socialist Commonwealth apart from the State and behind the back of the State. Utopianism, with its moral and religious motives and mediæval Communist traditions, was pervaded with that spirit of contempt for the State which was characteristic of the Catholic Church during the period of its splendour. Moreover Marx, who recognised all practical forms of power, even if he did not always estimate them at their true value, saw in the State an executive power which it was a question of overturning and using as an extremely powerful instrument in the social revolution. As a result of his excursions into politics and French and English Socialism, Marx gave up Hegel's overstrained idea of the State and accepted the view current in Western European thought of the time; but he interpreted the State in the sense of the doctrine of the class struggle as the executive council of the ruling and possessing classes.

The impressions, the ideas, the experiences and the modes of thinking which took root in the mind of Marx during the evolution of the fundamental principles of his sociological and historical system dominated the whole of his life's work.

Marxism is quite a natural growth of the revolutionary soil of the first half of the nineteenth century. Marx completes the social revolutionary doctrines of that time, of which he is, as it were, the executor. All his thoughts and sentiments are deeply rooted in it; they have nothing specifically Jewish about them. I know of no Jewish philosopher, sociologist, or poet who had so little of the Jewish character as had Marx.

II. The Communist Manifesto.

As in Paris, so too in Brussels, Marx frequented the society of German working men in order to instruct them by lectures and by conversation. He

was loyally seconded by Engels, who had more time and more money to devote to this task, and who worked for the new doctrine in Paris, Cologne, Elberfeld and other towns. Since 1836 the German working men living abroad had been organised in the League of the Just, which from 1840 had its head-quarters in London. The individual groups were kept in touch with one another by means of Communist correspondence committees. The Paris and Brussels groups drew the attention of the London Committee to Marx, and in January, 1847, Joseph Moll, one of its members, was commissioned to go to Brussels and obtain information about Marx. — (“Mehring’s Introduction to the Reprint of the Cologne Communist Proceedings,” published by *Vorwärts*, Berlin, 1914, pp. 10-11.) The result was the transformation of the League of the Just into the League of Communists, which held its first Congress in London in the summer of 1847, Engels and Wilhelm Wolff (Lupus) being among those present as delegates. At the second Congress, held in London towards the end of November and beginning of December, 1847, Marx also appeared, and together with Engels was commissioned to prepare a new program. The new program is the Communist Manifesto. Engels had come from Paris, Marx from Brussels. Before leaving Paris, Engels wrote a letter to Marx, dated November 24, in which he speaks as follows on the subject of the Manifesto:

“Just think over the confession of faith a little. I believe it will be best if we leave out the form of catechism and entitle the thing ‘The Communist Manifesto.’ And then, as more or less of it will consist in historical narrative, the present form is quite unsuitable. I am bringing along the manuscript which I have written; it is a plain narrative, but is badly put together, and has been done in a frightful hurry. I begin, ‘What is Communism?’ and then straight away with the proletariat — the history of its origin, difference from earlier workers, development of the antagonism of the proletariat and the middle class, crises, conclusions, with all kinds of secondary considerations thrown in, and lastly party politics of the Communists, as much as is good for the public to know.” — (“Correspondence of Marx and Engels,” Vol. I., p. 84.)

Engels’ draft of the Communist Manifesto has been edited by Eduard Bernstein. — (“Grundsätze des Kommunismus,” published by *Vorwärts*, 1914.) A comparison of this draft with the actual “Communist Manifesto” makes evident the full extent of Marx’s intellectual superiority to Engels.

The Communist Manifesto contains four main groups of ideas: (1) The history of the evolution of the middle class, its character, its positive and negative achievement — modern capitalism and the rise of the proletariat. (2) Theoretical conceptions and conclusions — the doctrine of the class struggle and the rôle of the proletariat. (3) Practical application — revolutionary action by the Communists. (4) Criticism of other Socialist schools. The last section has long ago lost all practical interest, so that we need only deal with the first three sections.

(1) The middle class developed in the bosom of feudal society, in the mediæval industrial towns. With the geographical discoveries of the sixteenth and seventeenth centuries its sphere of activity was extended; it revolutionised the methods of industry, agriculture and communication; it broke through the mediæval economic and political bonds; it overthrew feudalism, the guilds, the little self-governing regions, absolute monarchy, and established modern industry with its accelerated and concentrated production, middle-class franchise, the national State, and, at the same time, international trade. It was the middle class which first showed what human activity can accomplish. “It has achieved greater miracles than the construction of Egyptian pyramids, Roman aqueducts, or Gothic cathedrals, it has carried out greater movements than the migration of peoples or the crusades.... Although it is scarcely a century since it came to be the dominating class, the middle class has created more powerful and more gigantic forces of production than all past generations put together.” The subjugation of natural forces, machinery, the application of chemistry to industry and to agriculture, steamships, railways, electric telegraphs, the clearing of whole continents, making the rivers navigable, the conjuring forth of whole peoples out of the ground: that is the positive achievement of the middle class. Now for the negative: it created the proletariat, immeasurable, uncontrollable, anarchical economic conditions, periodical crises — poverty and famine in consequence of over-production and a glut of wealth, over-driving and reckless exploitation of the workers, whose labour is bought in exchange for the minimum quantity of the necessities of life. These facts show that the forces of production are more extensive and more powerful than is demanded by the conditions under which they are operative: the economic system can produce and deliver more goods than society can use under the existing laws concerning property, i.e., the distribution and the effective demand fall short of the manufacture and the

supply. The material forces of production press upon the limits imposed upon them by the laws of private property. This happens, too, because the working class must reduce its consumption of goods to a minimum in consequence of the existing laws of property, which give to capital the right of distribution. All these conditions taken together, the positive as well as the negative ones, make possible and give rise to the struggles of the workers against the middle class — and so the productive agents rise in rebellion. These struggles lead to the organisation of the workers in trade unions, to the awakening of class consciousness, and, as a result, to the formation of the political labour party.

(2) The movements within middle-class society, as well as in feudal and ancient society, where freeman and slave, patrician and plebeian, baron and serf, guild-master and journeyman, capitalist and working man stood and stand in constant antagonism to one another, prove that the whole history of mankind since the rise of private ownership is the history of class struggles, and that in these class struggles, carried on now openly, now under the surface, either new forms of society and of ownership, new economic systems arise or else end with the common destruction of the two classes. The antagonistic classes are supporters of conflicting economic interests, systems of ownership and ideals of culture. The craftsman and tradesman of the towns, the burgher, fought against the feudal lord and knight for individual property, for freedom of industry and trade, for freedom to dispose of personal property and for the national State. With the triumphal progress of the middle class private property fell into fewer and fewer hands. The proletarians are without property, they have no share in the wealth of their country; on the other hand, the production of capital becomes more and more a matter of common co-operation, and capital becomes a joint product. The proletariat can, accordingly, no longer fight for individual ownership but for the socially conducted utilisation of the means of production belonging to the community and of the goods produced. The middle class has therefore created in the proletariat a social class which must have as its object to do away with the middle class system of ownership and to set up the proletarian system of common ownership.

(3) In this struggle of the working classes the Communists are therefore the pioneers of the movement. They are at once the philosophers and the self-sacrificing champions of the proletariat awakened into class consciousness. “The Communists are not a special party in contradistinction

to the other Labour parties. They have no interests apart from the interests of the whole proletariat. They set up no special principles according to which they wish to mould the proletarian movement.” The Communists lay stress on the common interests of the whole proletariat and of the collective movement. Their aim is the organisation of the proletariat into a class, the overthrow of middle-class domination, and the conquest of political power by the proletariat. They support everywhere “any revolutionary movement against the existing social and political conditions. In all these movements they emphasise the question of property, in whatever state of evolution it may appear, as the foundation of the movement. And finally the Communists work everywhere for the union and agreement of democratic parties⁶ of all nationalities. The Communists disdain to conceal their views and intentions. They declare openly that their ends can only be attained by the forcible overthrow of every obtaining order of society. Let the ruling classes tremble before a Communist revolution; the workers have nothing to lose by it but their chains. They have the world to win. Workers of every land, unite!”

From the standpoint of social philosophy, the Manifesto, a document reflecting its time, is almost perfect. Strong emotion and extraordinary intellectual power are united in it. Years of study of one of the boldest and most fertile minds are here welded together in the glowing heat of one of the most active of intellectual workshops. But the work is not free from logical flaws. In the passages we have quoted the part played in history by the middle class is extolled by Marx; yet in the last few lines of the very same section he declares that “the middle class is the unwitting and inert instrument of industrial progress,” and still more scathing is his criticism in the second section, where the middle class is accused of indolence. “It has been objected that, if private property were done away with, all activity would cease and a general laziness set in. According to that, middle-class society would have been ruined by idleness long ago; for those of its members who work gain nothing, and those who gain do not work.” That is as much as to say that the middle class is lazy and does not work, and yet the Manifesto says that the middle class has achieved more marvellous works than Egypt, Rome, and the Middle Ages, and that, in its reign of power of scarcely a hundred years, it has created more powerful and more gigantic forces of production than all past generations put together. How

can a class which does not work produce more marvellous works than the whole ancient and mediæval world?

Marx frees himself later from this inconsistency by ascribing surplus value solely to the operation of the variable part of capital (wage-labour) — a doctrine which he develops with iron logic in his principal work, “Capital.”

III. The Revolution of 1848.

The ink had hardly dried on the Communist Manifesto when the February Revolution broke out. The crowing of the Gallic cock soon awoke an echo in the various German States, whilst in Brussels the democrats were attacked and ill-treated by the mob. One of the victims of this attack was Karl Marx, who was, moreover, banished shortly afterwards by the Belgian Government. This action, however, did not cause him any embarrassment, as he was ready in any case to proceed to Paris, whither the Provisional Government of the French Republic had already invited him in the following terms:

“Paris, March 1, 1848.

“Brave and Faithful Marx,

“The soil of the French Republic is a place of refuge for all friends of freedom. Tyranny has banished you; France, the free, opens to you her gates — to you and to all who fight for the holy cause, the fraternal cause of every people. In this sense shall every officer of the French Government understand his duty. *Salut et Fraternité.*

Ferdinand Flocon,
Member of the Provisional Government.”

The stay in Paris was, however, of short duration. Marx and Engels gathered together the members of the League of Communists and procured them the means for returning to Germany to take part in the German revolution. They themselves travelled to the Rhineland and succeeded in getting the establishment of the newspaper planned in Cologne into their hands. On the first of June, 1848, the *Neue Rheinische Zeitung* appeared for

the first time. It goes without saying that the editor was Karl Marx, and among his collaborators were Engels, Freiligrath, Wilhelm Wolff, and Georg Weerth. Occasionally, too, Lassalle sent contributions. It is but rarely given to a daily paper to have such an editorial staff. In the third volume of his “Collected Papers of Marx and Engels,” Franz Mehring gives a selection of the articles which appeared in this journal. They are still worth reading. Here are a few examples. After the fall of Vienna he wrote an article concluding with the following words: “With the victory of the ‘Red Republic’ in Paris the armies from the inmost recesses of every land will be vomited forth upon the boundaries and over them, and the real strength of the combatants will clearly appear. Then we shall remember June and October, and we too shall cry, ‘Woe to the vanquished!’ The fruitless butcheries which have occurred since those June and October days ... will convince the peoples that there is only one means of shortening, simplifying, and concentrating the torturing death agonies of society — only one means — revolutionary terrorism.” — (*Neue Rheinische Zeitung*, November 6, 1848.)

Or take, for example, this passage from the last article of the paper, when on May 18, 1849, it succumbed to the “craft and cunning of the dirty West Kalmucks” (i.e., the Prussians).

“In taking leave of our readers we remind them of the words in our first January number: ‘Revolutionary upheaval of the French working class, general war — that is the index for the year 1849. And already in the east a revolutionary army comprised of warriors of all nationalities stands confronting the old Europe represented by and in league with the Russian army, already from Paris looms the Red Republic.’”

In reading these extracts one has only to substitute Russia for France and Moscow for Paris and we get at one of the sources of Lenin’s and Trotsky’s revolutionary policy. The articles written by Marx in 1848 and 1849 have supplied the Bolsheviks their tactics.

The censorship, Press lawsuits, and the decline of the revolution severed the life threads of the paper after scarcely a year of its existence. Marx sacrificed everything he had in money and valuables — in all, 7,000 thalers — in order to satisfy creditors and to pay the contributors and printers. Then he travelled to Paris, where he witnessed not the triumph of the Red Republic but that of the counter-revolution. In July, 1849, he was banished by the French Government to the boggy country of Morbihan, in Brittany;

he preferred, however, to go over to London, where he remained to the end of his life.

IV. Days of Cloud and Sunshine in London.

Marx lived for more than a generation in London. Half of this time was spent in a wearying struggle for existence, which, however, did not prevent him from collecting and systematising a vast amount of material for his life-work, "Capital," nor from taking a decisive part in the Labour movement as soon as the opportunity presented itself, as it did on the founding of the International. The first decade was particularly trying. A letter written on May 20, 1851, by Marx's wife to Weydemeyer, in America, gives an affecting picture of their poverty during these first years of exile. — ("Neue Zeit," 25th year, Vol. II., pp. 18-21.)

The attempt to continue the *Neue Rheinische Zeitung* under the title *Neue Rheinische Revue* had only the negative result of swallowing up Marx's last resources. How poor Marx then was can be judged from the fact that he had to send his last coat to the pawnshop in order that he might buy paper for his pamphlet on the Cologne Communist trial (towards the end of 1852). On top of all this, lamentable differences sprang up among the German exiles, who, deceived in their revolutionary illusions, overwhelmed one another with recriminations; an echo of these conflicts is heard in the pamphlet "Herr Vogt" (1860). Marx's only regular source of income in the years 1851-60 was his earnings as correspondent of the *New York Tribune*, which paid him at the rate of a sovereign per article, and this hardly covered his rent and the cost of newspapers and postage. Yet his articles were veritable essays, the fruit of researches which cost him a good deal of time. And in the midst of this penury the idea of writing a Socialistic criticism of political economy burnt within him. One might almost say that since 1845 this idea had allowed him no peace. Freiligrath's lines are, as it were, stamped upon him:

In the clouds his goal he planted; In the dust had he to live, Bare existence daily granted. Cramped, hemmed in on every side, Pinched by poverty and urged By want, he, of all denied, By necessity was scourged.

Only in the sixties did his fortunes improve. Small family inheritances, Wilhelm Wolff's legacy of over £800, and Engels' more plentiful and

regular help, which from 1869 onward amounted to about £350 annually, enabled Marx to write his “Capital,” the first volume of which, as is well known, is dedicated to Wilhelm Wolff.

To these relatively happy times belong Paul Lafargue’s reminiscences — (“Neue Zeit,” 9th year, Vol. I., pp. 10-17, 37-42) — of his intercourse with the Marx family. In particular he depicts the personality of the author of “Capital.” In the bosom of his family and among the circle of his friends on Sunday evenings Marx was a genial companion, full of wit and humour. “His dark black eyes sparkled with mirth and with a playful irony whenever he heard a witty remark or a prompt repartee.” He was a tender, indulgent father, who never asserted the parental authority. His wife was his helper and companion in the truest sense of the word. She was four years older than he, and notwithstanding her aristocratic connections and in spite of the great hardships and persecutions which for years she had to suffer by the side of her husband, she never regretted having taken the step which linked her destiny with that of Marx. She possessed a cheerful, bright disposition and an unfailing tact, easily winning the esteem of every one of her husband’s acquaintances, friends, and followers. “Heinrich Heine, the relentless satirist, feared Marx’s scorn; but he cherished the greatest admiration for the keen, sensitive mind of Marx’s wife. Marx esteemed so highly the intelligence and the critical sense of his wife that he told me in 1866 he had submitted all his manuscripts to her and that he set a high value upon her judgment.” Six children were born to the Marxes, four girls and two boys, of whom only three of the girls grew up — Jenny, who married Charles Longuet; Laura, who became the wife of Paul Lafargue; and the unhappy but highly-gifted Eleanor, who spent 14 sad years of her life by the side of Dr. Edward Aveling.

The sixties were undoubtedly the happiest years of Marx’s life, and seemed to promise an abundant harvest in his later life. But his health soon began to fail, and did not allow him to complete his work. The most productive years of Marx’s life were between 1837 and 1847 and between 1857 and 1871. All his valuable work falls within these years: the “Poverty of Philosophy,” the Communist Manifesto, his activity in the International, “Capital,” the Civil War in France (the Commune).

V. The International.

The economic studies necessitated by his book "Capital" led Marx into the study of the social history of England during the eighteenth and nineteenth centuries, and gave him an insight into the working-class movements of those times such as but few scholars, English or foreign, have acquired. He became familiar with the modes of thought and expression of the working-class revolutionary movements, and especially of the Chartist movement, with the surviving leaders and adherents of which he was personally acquainted. Always eager to obtain knowledge of the actual working-class movement and to take part in it, he watched the activities of the English working class, which in the fifties was mainly occupied with purely trade unionist questions, being, politically, still in the Liberal camp. A change seemed imminent, however, about the beginning of the sixties. The London Labour leaders began to think about a Parliamentary reform movement, about starting a campaign for universal suffrage, which was an old Chartist demand. Likewise they manifested an interest in the fate of Poland and in other international questions concerning liberty.

At the International Exhibition held in London in 1862, the Labour leaders made the acquaintance of a deputation of French working men, with whom they afterwards carried on a correspondence. In 1863 and 1864, in the course of this correspondence, the idea of founding an international union of workers was mooted; and in the fourth week of September, 1864, this idea was carried into effect. Labour delegates from Paris and London held a conference in London from the 25th to the 28th of September, and the event was celebrated by a public gathering in St. Martin's Hall on the evening of the 28th. Marx received an invitation to this meeting in order that the German workers might be represented there. This conference and meeting resulted in the formation of the International Working Men's Association. Committees and sub-committees were elected to draw up a declaration of principles and outline the constitution. One of Mazzini's followers and a Frenchman submitted schemes which were handed over to Marx to be elaborated by him. He consigned them to the waste-paper basket and wrote the "Inaugural Address," giving a history of the English workers since the year 1825, and deducing the necessary conclusions. The declaration of principles is entirely the work of Marx, and it is by no means a subtly and diplomatically conceived composition designed to please English and French working men; it consists essentially of Marxian ideas expressed in terms, however, which would appeal to English working men

of that time. “It was difficult,” writes Marx to Engels — (“Correspondence,” Vol. III., p. 191)— “so to arrange matters that our view should appear in a form which would prove acceptable to the working-class movement with its present outlook.... It needs time before the reanimated movement will allow of the old boldness of speech. One must go *fortiter in re, suaviter in modo* (firmly maintaining essential principles with a pleasant manner).”

The Inaugural Address sums up the history of the English working class from 1825 to 1864, and shows that from its struggles, as indeed from modern social history in general, the following lessons may be learnt by the proletariat: independent economic and political action by the working class; the turning to account of reforms forced out of the ruling classes by the proletariat; international co-operation of workers in the Socialist revolution and against secret, militarist diplomacy.

Marx devoted a great deal of his time during the years 1865 to 1871 to the International. Its progress awoke in him the greatest hopes. In 1867 he writes to Engels: “Things are moving. And in the next revolution, which is perhaps nearer than it seems, we (i.e., you and I) have this powerful machinery *in our hands*.” — (“Correspondence of Marx and Engels,” Vol. III., p. 406.)

The International passed through three phases: from 1865 to 1867 the followers of Proudhon held sway; from 1868 to 1870 Marxism was in the ascendant; from 1871 to its collapse it was dominated and ultimately broken up by the Bakunists. The followers of Proudhon, like those of Bakunin, were against political action and in favour of the federative economic form of social organisation, only the Bakunists were also Communists, whereas the followers of Proudhon had an antipathy to Communism. Both groups were in agreement with Marx only on the one point — that he made economics the basis of the working-class movement. Both groups, however, accused him of being dictatorial, of attempting to concentrate the whole power of the International in his own hands. Besides insurmountable theoretical differences, racial and national prejudices crept into the International as disintegrating factors. The Romance and Russian Anarchists looked upon Marx as a pan-German, and conversely, some Marxians considered Bakunin a pan-Slav. Even as late as 1914, in the first months of the war, Professor James Guillaume, the last of the Bakunists, wrote a pamphlet entitled “Karl Marx, Pangermaniste” (Paris).

Michael Bakunin (b. 1814, near Twer, in Russia; d. 1876, in Berne) lived and studied in Germany during the forties. In 1848 and 1849 he took part in the revolution, was arrested, then handed over to Russia and banished to Siberia, whence he escaped in 1856, afterwards living in various countries of Western Europe. He was an indifferent theorist, and contributed little to the enrichment of philosophical Anarchism, but he distinguished himself by his immense revolutionary activity and his capacity for sacrifice. The influence which he exercised sprang from his character. He had been acquainted with the Young Hegelians as well as with Marx, Engels, and Wilhelm Wolff since the beginning of the forties. Until the end of 1868 he acknowledged Marx as his intellectual leader, as is evident from the following letter which he addressed to Marx:

“123, Montbrillant, Geneva,
“December 22, 1868.

“Serno has shown me the portion of your letter which concerns me. You ask him whether I am still your friend. Yes, more than ever, my dear Marx, for now I understand better than ever how truly right you are when you advance along the high road of economic revolution and invite us to follow, and when you set those below us who stray into the side-tracks either of national or exclusively political enterprises. I am now doing the same thing that you have been doing for more than twenty years. Since my solemn public leave-taking from the bourgeois of the Berne Congress, I no longer know any other society, any other milieu, than the world of the workers. Henceforth my country is the ‘International,’ of which you are one of the most illustrious founders. You see, my dear friend, that I am your disciple — and I am proud of it. That will be enough to make clear my attitude and my feelings toward you.” — (“Neue Zeit,” 19th year, Vol. I., p. 6.)

Nevertheless, this discipleship did not hinder Bakunin from secretly forming a separate organisation which contributed to the break-up of the International. Moreover, the International was only a kind of school for Socialist officers who had yet to create their armies, but it proved even more successful than Marx himself could have expected. The fundamental principles of Marxism ousted every other social revolutionary system which had made itself prominent within the working-class movement.

VI. The Paris Commune.

On September 1, 1870, a part of the French Army was defeated near Sedan and compelled to capitulate on the following day. Among the prisoners was Louis Bonaparte, the French Emperor. The Empire fell on September 4, and France was proclaimed a Republic. On September 6 Marx wrote to Engels: "The French section of the International travelled from London to Paris in order to do foolish things in the name of the International. They want to overthrow the Provisional Government and set up a *Commune de Paris*." — ("Correspondence," Vol. IV., p. 330).

Although the Provisional Government of the newly-baked French Republic was in no wise made up of friends of the democracy, Marx and Engels expressed themselves *against* any revolutionary action by the Paris working class. In the second Address (or declaration) of the General Council of the International, written on September 9, and composed by Marx, the question is discussed as follows:

"Thus the French working class finds itself placed in extremely difficult circumstances. Any attempt to overthrow the new Government, when the enemy is already knocking at the gates of Paris, would be a hopeless piece of folly. The French workers must do their duty as citizens; but they must not let themselves be overcome by the national reminiscences of 1792.... They have not to repeat the past but to build the future. Let them quietly and with determination make the most of the republican freedom granted to them, in order to carry out thoroughly the organisation of their own class. That will give them new, Herculean strength for the rebirth of France and for our common task — the emancipation of the proletariat." — ("Civil War in France," Second Address.)

Marx then urged the French workers not to do anything foolish, not to set up a revolutionary Commune of Paris, but to make use of their republican liberties to create proletarian organisations and to save and discipline their forces for future tasks. Circumstances, however, proved much stronger than any words of wisdom. Goaded by the anti-democratic moves of the Government supporters, deeply humiliated by the defeats of the French army, burning with patriotism and whipped up into fury against the "capitulards," the Paris working men cast Marx's words to the winds

and rose in revolution on March 18, 1871, proclaiming the Paris Commune. Paris was to be the capital of a Socialist Republic. In seven weeks the Paris Revolution was overthrown — and “Vae victis!” (Woe to the vanquished!) Marx afterwards wrote the pamphlet on “The Civil War in France, 1871,” which is one of the most mature of his writings. He did not cut himself entirely adrift from the revolutionaries — the Bolsheviks of that time — but defended them with unsurpassable energy. It is the swan song of Marx and of the first International.

VII. The Evening of Life.

During the last twelve years of his life Marx had to fight almost uninterruptedly against various bodily ailments, all of which had their origin in his chronic liver complaint and over-exertion. His work, for which he had sacrificed, as he wrote to an American friend, “health, happiness and family,” remained unfinished. He devoted his enforced leisure to making a study of American agriculture and of rural conditions in Russia, for which purpose he learnt Russian; he likewise occupied himself with studies of the Stock Exchange, banking, geology, physiology, and higher mathematics. In 1875 he wrote his “Criticism of the Gotha Program” — (“Neue Zeit,” 9th year, Vol. I., No. 18) — which contains some very important data as to Marx’s attitude to the State, to the revolutionary period of transition from Capitalism to Socialism, and lastly to Socialist society itself.

He went to Karlsbad for the purpose of recovering his health. In 1877 and 1878 he was in some measure capable of carrying on his work, and set about arranging his manuscripts and getting the second volume of “Capital” ready for the press; it soon appeared, however, that his capacity for work had gone. The decline in body and mind could no longer be checked; even visits to French and Algerian watering-places proved ineffective. It was just at this time that Marx began to find recognition both in France and in England: Jules Guesde, Henry M. Hyndman, Belfort Bax set about spreading Marxian doctrines, and Marxian and anti-Marxian parties were formed. But the man to whom this recognition had come was already a ruin. Bronchial catarrh, inflammation of the lungs, spasmodic asthma, together with the loss of his wife on December 2, 1881, and of his eldest daughter (Mme. Longuet) in January, 1883, gave the finishing stroke to his enfeebled

body. On March 14, 1883, Marx breathed his last. Engels gives an account of the last moments in a letter to his American friend Sorge, dated March 15, 1883:

“Yesterday, at half-past two in the afternoon, the best time for visiting him, I went down to see him; everybody was in tears; it looked as if the end had come. I made inquiries, trying to get at the truth of the matter and to offer consolation. There had been a slight hæmorrhage, but a sudden collapse had supervened. Our good old Lena, who had tended him better than any mother does her child, went up, came down. He was half asleep, she said; I could go up. As we went in, he lay there, sleeping, never to wake again. Pulse and breathing had ceased. In those two minutes he had gone painlessly and peacefully to sleep.... Mankind is less by a head, and indeed by the most important head it had to-day. The working-class movement will pursue its course, but its central point, to which French, Russians, Americans, and Germans turned of their own accord in decisive moments, always to receive that clear, unambiguous counsel which genius and perfect mastery alone can give — is gone.”

On Saturday, March 17, he was buried in the Highgate Cemetery, London. Among those who spoke at the graveside were Friedrich Engels and Wilhelm Liebknecht. The former gave a brief account of his revolutionary struggles, in which he said:

“Just as Darwin discovered the law of the evolution of organic nature, so Marx discovered the evolutionary law of human history — the simple fact, hitherto hidden under ideological overgrowths, that above all things men must eat, drink, dress, and find shelter before they can give themselves to politics, science, art, religion, or anything else, and that therefore the production of the material necessities of life and the corresponding stage of economic evolution of a people or a period provides the foundation upon which the national institutions, legal systems, art, and even religious ideas of the people in question have been built, and upon which, therefore, their explanation must be based, a procedure the reverse of that which has hitherto been adopted. Marx discovered also the special law of motion for the modern capitalist mode of production and for the middle-class society which it begets. With the discovery of surplus value light was at once thrown upon a subject, all the earlier investigations of which, whether by middle-class economists or by Socialist critics, had been gropings in the dark....”

After him spoke Liebknecht, who had hastened from Germany to pay a last tribute to his friend and master:

“The dead one, whose loss we mourn, was great in his love and in his hate. His hate sprang from his love. He had a great heart, as he had a great intellect. He has raised social democracy from a sect, from a school, to a party, which now already fights unconquered, and in the end will win the victory.”

Engels, who outlived him by twelve years, edited the two last volumes of “Capital,” while Karl Kautsky, the disciple and successor of Engels and the real disseminator of Marxian doctrines, edited the three volumes of Marx’s historical studies on surplus value. The latter work is not far short of being a great history of political economy.

ENDNOTES.

⁶ By democratic parties were then understood working-class political movements, such as Chartism, etc.

IV. THE MARXIAN SYSTEM.

I. The Materialist Conception of History.

As a guide to his studies from 1843-4 onwards, Marx used the conception of history, or method of investigation, which — in contradistinction to the idealist conception of history of Hegel — was named materialistic. As its nature is dialectic — as it seeks to conceive in thought the evolving antagonisms of the social process — it is, like Hegel's dialectic, a conception of history and a method of investigation at the same time. Nowhere did Marx work out his method of investigation in a special and comprehensive form; the elements of it are scattered throughout his writings, particularly in the Communist Manifesto and in the "Poverty of Philosophy," and serve the purpose of polemics or demonstration. Only in the preface to his book, "On the Critique of Political Economy" (1859) did he devote two pages to a sketch of his conception of history, but in phraseology which is not always clear, sequential, or free from objection. It was the intention of Marx to write a work on Logic, where he would certainly have formulated clearly his materialistic dialectic. As, however, his fundamental ideas on this subject are available, we are able to extract the essentials of his position.

A glance over human history suffices to teach us that from age to age man has held to be true or false various opinions on rights, customs, religion, the State, philosophy, land-holding, trade, industry, etc., that he has had various economic arrangements, and forms of the State and of society, and that he has gone through an endless series of struggles and wars and migrations. How has this complicated variety of human thought and action come about? Marx raises that question, which, so far as he is concerned, does not aim in the first place at the discovery of the origin of thought, of rights, of religion, of society, of trade, etc.; these he takes to be historically given. He is rather concerned to find out the causes, the impulses, or the springs which produce the changes and revolutions of the essentials and forms of the mental and social phenomena, or which create the tendencies thereto. In a sentence: What interested Marx here was not the *origin*, but the development and change of things — he is searching for the dynamic law of history.

Marx answered: The prime motive power of human society, which is responsible for the changes of human consciousness and thought, or which causes the various social institutions and conflicts to arise, does not originate, in the first place, from thought, from the Idea, from the world-reason or the world-spirit, but from the material conditions of life. The basis of human history is therefore material. The material conditions of life — that is, the manner in which men as social beings, with the aid of environing nature, and of their own in-dwelling physical and intellectual qualities, shape their material life, provide for their sustenance, and produce, distribute and exchange the necessary goods for the satisfaction of their needs.

Of all categories of material conditions of existence, the most important is production of the necessary means of life. And this is determined by the nature of the productive forces. These are of two kinds: inanimate and personal. The inanimate productive forces are: soil, water, climate, raw materials, tools and machines. The personal productive forces are: the labourers, the inventors, discoverers, engineers, and finally, the qualities of the race — the inherited capacities of specific groups of men, which facilitate work.

The foremost place among the productive forces belongs to the manual and mental labourers; they are the real creators of exchange-value in capitalist society. The next place of importance is taken by modern technology, which is an eminently revolutionising force in society. — (“Capital” (German), Vol. I., Chapters 1, 12, 13 and 14, “Poverty of Philosophy” (German edition, 1885, pp. 100-101.))

So much for the conception “Productive Forces,” which plays an important part with Marx. We come now to the other equally important notion, “Conditions of production.” By this phrase Marx understands the legal and State forms, ordinances and laws, as well as the grouping of social classes and sections: thus, the social conditions which regulate property and determine the reciprocal human relations in which production is carried on. The conditions of production are the work of men in society. Just as men produce various material goods out of the materials and forces made available to them by Nature, so they create out of the reactions of the productive forces upon the mind definite social, political, and legal institutions, as well as systems of religion, morals, and philosophy.

“Men make their own history, but do not so spontaneously in conditions chosen by them, but on the contrary, in conditions which they have found ready to hand transmitted and given.” — (Marx, “The Eighteenth Brumaire,” I.)

That is to say, under the influence of productive work and its needs, men build their form of society, their State, their religion, their philosophy and science. The material production is the substructure or the groundwork, while the corresponding political, religious, and philosophical systems are the superstructure. And in such a manner that the superstructure corresponds to the foundation, lends it strength, and promotes its development.

The foundation is material, and the superstructure is the psychical reflex and effect.

In broad outlines this conception may be illustrated somewhat as follows:

Primitive human groups lived under Communism and were organised according to blood relationship. Their deities have the characteristics of their natural environment, and reflect the physical effects of this environment upon the primitive mental life of the “savage”; their religion, their morality, and their laws promote the communal life and the tribal discipline. Feudal society is based on the possession of land by the nobles and on the industrial labour of the corporations of the towns. The inherited religious ideas are soon transformed in accordance with the dominant interests of these historical periods (primitive Christianity became a State religion); all religious, ethical, and philosophical ideas antagonistic to these interests were fought and persecuted. The middle-class society, which is based on personal property, is endeavouring to sweep away all vestiges of communal and corporation rights, to set free the individual, to mobilise labour and property, to abolish Feudalism and the old Church and monasterial institutions, and to put in their place the individual relation between man and God, or the personal conscience (the Reformation), introducing individual rights as well; it struggles against the independent sovereignty of the feudal domains, and labours for a united national territory, which will afford greater scope to trade and commerce; it supports Absolutism, so long as the latter is in conflict with the feudal lords; and when, afterwards, Absolutism is a hindrance to the development of middle-class society, this also is fought and a constitutional monarchy or a republic

demanded. And all this takes place not because certain human intelligences, by reason of more intense thought, or enlightenment, or the call of a supernatural power, are primarily at work, but as a consequence of the influence of the material basis, of the economic foundation of society, upon the mind, which translates and transforms these external realities into religious, juridical, and philosophic conceptions:

“It is not the consciousness of men which determines their existence, but, on the contrary, their social existence determines their consciousness.” — (Marx, Preface to “Critique of Political Economy.”)

Man, even the most heroic, is not the sovereign maker and law-giver of social life, but its executive; he only follows out the tendencies and currents set up by the material foundation of society. Nevertheless, a great deal depends upon the executive officials. If they possess comprehensive knowledge, energetic natures, and outstanding capacities, they are able, within the boundaries drawn for them, to accomplish great things, and to accelerate the development.

“Up to the present the philosophers have but interpreted the world; it is, however, necessary to change it.” — (Marx, “Theses to Feuerbach.”)

We have referred in various places to interests. We are not to understand by this personal, but general social or class interests. Marx is not of the opinion that everybody acts in accordance with his personal welfare. This is not Marxian doctrine, but that of the middle-class moral philosophers, like Helvetius (1715-1771) and Jeremy Bentham (1748-1832), who regarded pleasure and pain of the individual as the measure and motive of his actions and conduct. Marx is rather of the opinion that men often, in the most important events of their lives, act contrary to their personal interests, as in their feelings and thoughts they identify themselves with that which they hold to be the interests of the community or of their class. According to Marx, individual interest generally plays a slight part in history. He is preoccupied with the collective interest of social production. Only the latter does he hold to be determining in the formation of the intellectual superstructure.

Up till now we have only spoken of various forms of production and society, and their corresponding mental systems. But we do not yet know why and how one form of production and society becomes obsolete and gives place to another, that is, how and why revolutionary changes are

brought about. Or in other words: we have hitherto considered the statics of society; we will now look at its dynamics.

The revolutionary changes in society depend on two groups of phenomena, which, although casually connected with each other, yet work differently. One of these groups of phenomena is technical, and consists in changes in the productive forces. The other group, which is the effect of the first, is of a personal nature, and consists in struggles between the social classes. Let us consider the first group of causes.

As the productive forces expand, through greater skill on the part of the worker, through discoveries of new raw material and markets, through the invention of new labour processes, tools and machines, and through the better organisation of trade and exchange, so that the material basis or the economic foundation of society is altered, then the old conditions of production cease to promote the interests of production. For the conditions of production: the former social classes, the former laws, State institutions, and intellectual systems were adapted to a state of the productive forces which is either in process of disappearing, or no longer exists. The social and intellectual superstructure no longer corresponds to the economic foundation. The productive forces and the conditions of production come into conflict with each other.

This conflict between the new reality and the old form, this conflict between new causes and the obsolete effects of bygone causes, begins gradually to influence the thoughts of men. Men commence to feel that they are confronted with a new external world, and that a new era has been opened.

Social divisions acquire a new significance: classes and sections which were formerly despised gain in social and economic power; classes which were formerly honoured decline. While this transformation of the social foundation is proceeding, the old religious, legal, philosophical, and political systems cling to their inherited positions, and insist on remaining, although they are obsolete and can no longer satisfy mental needs. For human thought is conservative: it follows external events slowly, just as our eye perceives the sun at a point which the sun has in reality already passed, as the rays require several minutes of time in order to strike our optic nerves. We may recall Hegel's fine metaphor: "The Owl of Minerva begins its flight only when twilight gathers." However late, it does begin. Great thinkers gradually arise, who explain the new situation, and create new

ideas and trains of thought which correspond to the new situation. The human consciousness gives birth to anxious doubts and questionings, and then new truths; leading to differences of opinion, disputes, strifes, schisms, class struggles, and revolutions.

In the next chapter we will consider more closely the class struggle between Labour and Capital. Meanwhile, we will look at the class struggle generally.

In primitive societies, where private property is yet unknown, or still undeveloped, there are no class distinctions, no class domination, and no class antagonisms. The chief, the medicine man, and the judge regulate or supervise the observance of the customary usages, religious ceremonies, and social arrangements. But as soon as the old order is dissolved, and private property develops, in consequence of trade with other peoples or through wars, there arise classes of those who possess and those who do not. The possessing class carries on the Government, makes laws, and creates institutions, which chiefly serve the end of protecting the interests of the possessing and ruling classes. The intellectual structure of the class society likewise corresponds to the interests of those who possess and rule. So long as these interests promote the common good in some measure, so long as the old forms of production and the old conditions of production are largely in harmony with each other, a certain truce prevails between the classes. But should there set in the above-mentioned opposition between the productive forces and the conditions of production, the latter will cease to satisfy the oppressed classes, and class conflicts will arise, which will either result in legal compromises (reforms) or will end in the overthrow of the society concerned, or will lead to a new set of conditions. Ancient history (Hebrew, Greek, Roman) is full of these social struggles; all the great reform laws of these peoples were attempts to establish social peace, but the rich and the poor, the Patricians and the Plebeians, the Slaves and Freemen, continued their struggles until the downfall of the old world, which has bequeathed to us great intellectual treasures as the fruit of these struggles. In the Middle Ages social struggles between the feudal lords and the traders, between nobles and peasants, were kindled. In more recent times the middle classes fought Autocracy and Squirearchy, and at length the proletariat was pitted against the bourgeoisie — class struggles which led to rebellions and revolutions, and powerfully influenced the intellectual life.

From these historical antagonisms and struggles arose the intellectual and political antagonisms, personified by the leaders of the social groups and classes, of which world-history relates: opposing religious and philosophical systems: Brahma and Buddha, Baal and Jahveh, National God and Universal God, Heathendom and Christendom, Catholicism and Protestantism, Materialism and Idealism, Realism and Nominalism. However abstract or metaphysical, however remote from actual life and material production they may appear to be, nevertheless, in the last resort they are to be traced back through many intermediate stages to changes in the economic foundation of the society in question, to the contradiction between this foundation and the conditions of production, as well as to the great struggles between conflicting interests which spring therefrom. The ethical, political, and politico-economic systems which strive with each other for mastery, as well as national and world wars, are separated from the real basis of society by a progressively smaller number of intermediate stages: the questions of idealist or utilitarian ethics, monarchy or republic, oligarchy or democracy, protection or free trade, State regulation or free scope for the economic forces, Socialism or private enterprise, etc., however lofty and humanitarian may be the arguments and ideal motives which their champions may adduce, are connected with the material foundation and the conditions of production which have come into conflict with it.

Marx and Engels have set forth this conception in the Communist Manifesto, in popular form, as follows:

“Does it require deep intuition to comprehend that man’s ideas, views, and conceptions, in one word, man’s consciousness, changes with every change in the conditions of his material existence, in his social relations and in his social life?

“What else does the history of ideas prove than that intellectual production changes in character in proportion as material production is changed. The ruling ideas of each age have ever been the ideas of its ruling class.

“When people speak of ideas that revolutionise society they do but express the fact that within the old society the elements of a new one have been created, and that the dissolution of the old ideas keeps even pace with the dissolution of the old conditions of existence.

“When the ancient world was in its last throes the ancient religions were overcome by Christianity. When Christian ideas succumbed in the eighteenth century to rationalist ideas, feudal society fought its death-battle with the then revolutionary bourgeoisie. The ideas of religious liberty and freedom of conscience merely gave expression to the sway of free competition within the domain of knowledge.”

Now one step farther. When the conditions of production, the social divisions into classes, and the laws of property become fetters to the productive forces, when the conflict of interests condense themselves into class struggles, then comes a period of social revolution.

“With the change of the economic foundation the entire immense superstructure is more or less rapidly transformed. In considering such transformations the distinction should always be made between the material transformation of the economic conditions of production which can be determined with the precision of natural science, and the legal, political, religious, æsthetic, or philosophic — in short, ideological forms in which men become conscious of this conflict and fight it out. Just as our opinion of an individual is not based on what he thinks of himself, so we are not able to judge of such a period of transformation by its own consciousness; on the contrary, this consciousness must rather be explained from the contradictions of material life, from the existing conflict between the social forces of production and the conditions of production.” — (Preface to “Critique of Political Economy.”)

The revolutionary period only closes when the social order that had become full of contradictions liberates the productive forces and strikes off their fetters, and creates new conditions of production which correspond to them. The old society, which is doomed to disappear, evolves the new conditions of existence before it sinks into oblivion. The men who assist the progress of the new society accordingly occupy themselves with problems which they are able to solve, as the means thereto are given in the material development. Such problems are set before them because, regarded from the theoretical standpoint, they are the mental reflex of the contradictions and revolutionary tendencies within society.

Accordingly, the essence of the historical development of human society has been so far the progressive dialectical unfolding and perfection of the productive forces.

“In broad outlines,” says Marx, “we can designate the Asiatic, the ancient, the feudal, and the modern bourgeois methods of production, as so many epochs in the progress of the economic formation of society. The bourgeois relations of production are the last antagonistic form of the social process of production — antagonistic not in the sense of individual antagonism, but of one arising from conditions surrounding the life of individuals in society; at the same time the productive forces developing in the womb of bourgeois society create the material conditions for the solution of that antagonism. This social formation constitutes, therefore, the closing chapter of the prehistoric stage of human society.”

Prehistoric stage of human society! What significant words! The capitalist economic order is the last phase of this stage, which is written in streams of blood and tears of the dispossessed and exploited, and to which is given the task of developing the productive forces and liberating men from the material fetters, so that they may enter into a life of mental culture. The materialist conception of history, unethical and unidealist like all natural science, opens up wide and elevating prospects. During thousands of years man struggled on the physical plane to obtain release from the animal kingdom, and was subjected to the discipline of unfeeling nature. After he had emerged from the animal kingdom, man laboured for thousands of years to lay the foundation of human society, a process which was performed under the hunger whip of stern taskmasters, and which powerfully stimulated the intellectual capacities of men, but only disclosed the ideal of justice and humanity as a remote and inaccessible star.

The materialist conception of history has shown itself to be a fruitful method of historical investigation. Some aspects of this idea were uttered both before and during Marx’s lifetime. The revolution in the positions of classes and the struggles which followed hard on the English industrial revolution (1760-1825), and everywhere attended the transition from an agrarian to an industrial State, were too palpable to be overlooked. It was Marx who fused these ideas, with the aid of the Hegelian dialectics made of them a method of investigation, and pressed them into the service of Socialism and historical research.

II. Classes, Class Struggles, and Class-Consciousness.

One of the most important contributions of Marx to the understanding of historical processes is his conception of social classes and of class struggles. Although, prior to Marx, there were historians and politicians who pointed out the part played by social classes in politics and in social convulsions, it was Marx who first grasped this conception in its entire scope and significance, giving it precise form, and making it an essential part of political and social thought. He refers to the subject in the Communist Manifesto in the following terms:

“The Socialist and Communist systems properly so called, those of St. Simon, Fourier, Owen, and others, spring into existence in the early undeveloped period of the struggle between proletariat and bourgeoisie. The founders of these systems see, indeed, the class antagonisms, as well as the action of the decomposing elements in the prevailing form of society. But the proletariat, as yet in its infancy, offers to them the spectacle of a class without any historical initiative or any independent political movement.”

The classification of the various groups of society, or the division of human society into classes, is as logical a process, that is, a result attained by the operations of reason, as the division of animals, plants, and minerals into various classes. A specific group of social beings, which bear the stamp of common characteristics, is put in a certain class by social science. This classification cannot be made by purely empirical methods of immediate sensuous perceptions. It cannot be determined from the appearance of modern men, whether they are capitalists or workers. We must look for certain scientifically established features which determine the social classification of men. As we have just seen, Marx held economic facts to be fundamental, and he contended that the economic characteristics were valid for purposes of classification. In his view, the manner in which a specific human group obtained its sustenance was the chief characteristic. Men whose chief means of life are wages form the working class. Men whose most important source of livelihood is the ownership of capital (land, buildings, workshops, and raw material) form the capitalist class. It is of little moment that a worker owns a savings-bankbook, and draws interest or dividends from a co-operative society, or that a capitalist personally supervises his undertaking, or organises his business, so that his profits partly consist in wages of superintendence or salary. The outstanding feature is that the chief interest of the worker is concentrated on wages, whilst that of the capitalist is directed on property. It goes without saying

that the social classes are not completely homogeneous. Like botanical and zoological classes, they may be divided into kinds and species; the working classes include well-paid hand and brain workers, as well as sweated sections; but all the subdivisions of the social classes possess the common outstanding quality of the same source of livelihood, which is either personal labour or the possession of capital. One class disposes only of labour-power, while the other class owns the means of production.

Between these two classes, says Marx, there are deep-seated, unbridgeable antagonisms, which lead to a class struggle. The antagonisms are primarily of an economic nature. The wage-earners, as the owners of labour power, are constrained to sell this as dear as possible, i.e., to obtain the highest possible wages, whereas the owners of capital endeavour to buy such labour-power as cheap as possible, i.e., to pay the least possible wages. This antagonism is indeed fundamental, but, at first sight, does not touch the intellectual sphere very deeply. On the surface, this antagonism is only one as between buyer and seller, but in reality the distinction is very great, as the seller of labour-power will quickly starve if he does not market his commodity. The owner of the means of production is therefore in a position to cause the seller of labour-power to starve, if the latter does not accept the conditions which the capitalist imposes. Ownership of capital reveals itself as a power that can oppress the owner of labour-power.

This antagonism leads to the formation of Trade Unions. It is also the prime cause of the class struggle, but mere trade unionism is but its incipient stage. It develops into a class struggle when the workers recognise that their condition of subjection is not a temporary state, but the result of the economic system of private capitalism, that the subjection will last so long as this economic system exists, and that the latter could be replaced by an economic order in which the means of production belong to all the members of society. The wage-workers only participate in the class struggle when they learn to think in a Socialist sense, when hostility to the existing social order develops out of the sporadic and unrelated wage struggle and actions of Trade Unions, and when the proletariat, as an organised class, turns from the preoccupations of the present to the tasks of the future, and strives to change the basis of society from private property to common property. The workers then become aware that there can be neither freedom nor equality for them in the existing society, and that their emancipation can only be attained through Socialism. The class struggle may, however, stop

short at the recognition of these facts. The dialectical movement will be incomplete if the working class does not take its fate into its own hands, and is not convinced that it has the power to achieve its own emancipation, and therefore contents itself with small social reforms, or relies on noble-minded and benevolent men and heroic redeemers. This was actually the case in the beginnings of the Socialist movement, when the workers saw in Socialism the only way out, but were still too weak to take their fate into their own hands. This was the period which Marx called Utopian, when outstanding personalities spread Socialist ideas, and made Socialist plans and experiments to free the labouring masses. As these personalities knew the impotence of the masses, they turned to philanthropists and humane rulers, and sought to convince them that reason, justice, and the general welfare demanded that Socialism should be introduced, and poverty, misery, and their consequences abolished. This period of Utopian Socialism gave way before the further development of industry, the progress of machine technique, the centralisation and concentration of the means of production and exchange, which brought with it an increase in the number, strength, organisation, and class-consciousness of the working classes. It is the centralisation of the means of production and exchange, in particular, which renders it possible for the working class, by paralysing industry and power stations, to cause the whole of society to feel that living labour-power forms the soul of the economic life.

At the same time Socialist investigators appear, who not only show the reasonableness and justice of Socialism, but exhibit the proof that the new economic order of Socialism is being prepared in the womb of Capitalism, and that therefore the aspirations of the worker are in harmony with the course of social development.

In this wise, a science and an aspiring Socialist movement founded upon reality develops from Utopian Socialism, and, conscious of class, of power, and of aim, enters upon the decisive struggle with the capitalist economic order. The class struggle acts as a lever of social revolution.

The original antagonism of the worker and capitalist over wages and hours of labour becomes an impassionate struggle of two classes over the question of the maintenance or transformation of the social and economic system — one of which classes fights for the existing order of private property and the other for the coming Socialistic system. Great social class struggles inevitably become political struggles. The immediate object of the

struggle is the possession of the power of the State, with the aid of which the capitalist class endeavours to maintain its position, whilst the working class aims at the conquest of the power of the State in order to accomplish its larger objects.

The following chapter will show the direction taken by the Labour movement. Here we will but briefly refer to the profound influence of Marx's doctrine of the class struggle as exercised in political thought. Prior to Marx, political thought and the struggles of political parties seemed to revolve around ideas and great personalities. Ideology and hero-worship were prevalent. Now, political thought, consciously or unconsciously, proceeds along class and economic lines. This is equally true of historical investigations. These new political and historical orientations are largely the result of Marx's life-work.

Rigidly conceived and applied, the Marxian doctrine of the class-struggle may lead to ultra-revolutionary tactics of the Socialist and Labour movement, to the system of Workers' Councils, and Proletarian Dictatorship. If the emerging class and its struggle constitutes the lever of social revolution and the impulse of the dialectical social process, the Dictatorship of the Proletariat is justified, and in any case, democracy, which includes both the capitalist and working class, cannot be the State form during the transition period from private property to Socialism. Considered from the economic standpoint, political democracy is generally impossible, or only sham democracy so long as economic inequality exists. The Communist Manifesto does not contain a single political democratic reform. The conclusion can be drawn from Marx's idea, as a whole, that in his estimation, the class stood higher than so-called democracy. This is one of the sources of Bolshevism.

III. The Role of the Labour Movement and the Proletarian Dictatorship.

The Labour Party is the political expression of the whole Trade Union movement so far as the latter formulates national demands, directed towards the State and society generally. The Labour Party will function the more effectively, and be able to accomplish its allotted task, as its foundation — the Trade Union movement — becomes established and strengthened, and the more comprehensive will be its effects. The Trade Unions are not

merely to be satisfied with the work of the present, but are to become the focus and centre of gravity of the proletarian aspirations which arise out of the social transformation process, and are to work for the abolition of Capitalism. The most effective lever for the achievement of this object is the conquest of political power. With its aid the proletariat can consciously carry out the transformation of a Capitalist into a Communist society. To this transformation, there also corresponds a political transition period, the state of which can be nothing else than a revolutionary Dictatorship of the Proletariat. — (Marx, Letter to the German Social Democracy, 1875, on their Gotha Programme.)

Marx considered himself to be the real author of the idea of the Dictatorship of the Proletariat. In a letter written by him, in 1852, to his American friend, Weydemeyer, he declares:

“As far as I am concerned, I can’t claim to have discovered the existence of classes in modern society or their strife against one another. Middle-class historians long ago described the evolution of the class struggles, and political economists showed the economic physiology of the classes. I have added as a new contribution the following propositions: (1) that the existence of classes is bound up with certain phases of material production; (2) that the class struggle leads necessarily to the Dictatorship of the Proletariat; (3) that this dictatorship is but the transition to the abolition of all classes and to the creation of a society of free and equal.” — (“Neue Zeit,” Vol. XXV., second part, p. 164.)

With the exception of the year 1870, Marx remained true to his doctrine of Proletarian Dictatorship: he thought in 1875 as he did in 1847, when he sketched the groundwork of the Proletarian Dictatorship in the Communist Manifesto:

“The first step in the revolution by the working class is to raise the proletariat to the position of ruling class, to win the battle of democracy.

“The proletariat will use its political supremacy to wrest, by degrees, all capital from the bourgeoisie, to centralise all instruments of production in the hands of the State, i.e., of the proletariat organised as the ruling class; and to increase the total of productive forces as rapidly as possible.

“Of course, in the beginning, this cannot be effected except by means of despotic inroads on the rights of property, and on the conditions of bourgeois production; by means of measures, therefore, which appear economically insufficient and untenable, but which, in the course of the

movement, outstrip themselves, necessitate further inroads upon the old social order, and are unavoidable as a means of entirely revolutionising the mode of production.”

But suppose that it is not the revolutionary working class which first attains to power in the revolution, but the democracy of the lower middle class and the social reformists. In this case, Marx gives the following advice: “Separate from it, and fight it.” In the address to the League of Communists in 1850 he said:

“It may be taken for granted that in the bloody conflicts that are coming, as in the case of previous ones, the courage, resolution, and sacrifice of the workers will be the chief factor in the attainment of victory. As hitherto, so in this struggle, the mass of the lower middle class will maintain an attitude of delay, irresolution, and inactivity as long as possible, in order that, as soon as victory is assured, to arrogate it to themselves and call on the workers to remain quiet, return to work, avoid so-called excesses, and to exclude the proletariat from the fruits of victory. It is not in the power of the workers to hinder the lower middle classes from doing this, but it is within their power to render their success over the armed proletariat very difficult, to dictate to them such conditions that from the beginning the rule of the middle-class democrats is doomed to failure, and its later substitution by the rule of the proletariat is considerably facilitated.

“The workers must, during the conflict and immediately afterwards, as much as ever possible, oppose the compromises of the middle class, and compel the democrats to execute their present terrorist threats. They must aim at preventing the subsiding of the revolutionary excitement immediately after the victory. On the contrary, they must endeavour to maintain it as long as possible.

“Far from opposing so-called excesses, and making examples of hated individuals or public buildings to which hateful remembrances are attached, by sacrificing them to the popular rage, such examples must not only be tolerated, but their direction must even be taken in hand. During the struggle and after the struggle, the workers must seize every opportunity to present their own demands side by side with those of the middle-class democrats. The workers must demand guarantees as soon as the middle-class democrats propose to take the government in hand. If necessary, these guarantees must be exacted, and the new rulers must be compelled to make every possible promise and concession, which is the surest way to

compromise them. The workers must size up the conditions in a cool and dispassionate fashion, and manifest open distrust of the new Government, in order to quench, as much as possible, the ardour for the new order of things and the elation which follows every successful street fight. Against the new official Government, they must set up a revolutionary workers' government, either in the form of local committees, communal councils, or workers' clubs or workers' committees, so that the democratic middle-class government not only immediately loses its support amongst the working classes, but from the commencement finds itself supervised and threatened by a jurisdiction, behind which stands the entire mass of the working class. In a word: from the first moment of victory the workers must no longer level their distrust against the defeated reactionary party, but direct it against their former allies, who would seek to exploit the common victory for their own ends. The workers must be armed and organised to enable them to threaten energetic opposition to this party, whose treason to the workers will commence in the first hour of victory. The arming of the whole proletariat with rifles and ammunition must be carried out at once, and steps taken to prevent the reviving of the old militia, which would be directed against the workers. But should this not be successful, the workers must endeavour to organise themselves as an independent guard, choosing their own chief and general staff, with orders to support not the State power, but the councils formed by the workers. Where workers are employed in State service, they must arm and organise in a special corps, with a chief chosen by themselves, or form a part of the Proletarian Guard. Under no pretext must they give up their arms and equipment, and any attempt at disarmament must be forcibly resisted. Destruction of the influence of the middle-class democrats over the workers, immediate independent and armed organisation of the workers, and the imposition of the most irksome and compromising conditions possible upon the rule of the bourgeois democracy, which is for the time unavoidable.... We have noted that the Democrats come to power in the next phase of the movement, and how they will be obliged to impose measures of a more or less Socialistic nature. It will be asked what contrary measures should be proposed by the workers. Naturally, in the beginning of the movement the workers cannot propose actual Communist measures, but they can (1) compel the Democrats to attack the old social order from as many sides as possible, disturb its regular course, and compromise themselves, and concentrate in the hands of the

State as much as possible of the productive forces, means of transport, factories, railways, etc. (2) When the Democrats propose measures which are not revolutionary, but merely reformist, the workers must press them to the point of turning such measures into direct attacks on private property; thus, for example, if the small middle class propose to purchase the railways and factories the workers must demand that such railways and factories, being the property of the reactionaries, shall be simply confiscated by the State, without compensation. If the Democrats propose a proportional tax, the workers must demand a progressive tax; if the Democrats themselves declare for a moderate progressive tax, the workers must insist on a tax so steeply graduated as to cause the collapse of large fortunes; if the Democrats demand the regulation of the State debt, the workers must demand State bankruptcy. Thus the demands of the workers must everywhere be directed against the concessions and measures of the Democrats.... Further, the Democrats will either work directly for a Federal Republic, or, at least, if they cannot avoid the Republic one and indivisible, will seek to paralyse it by granting the greatest possible independence to the municipalities and provinces. The workers must set themselves against this plan, not only to secure the one and indivisible German Republic, but to concentrate as much power as possible in the hands of the State. They need not be misled by democratic platitudes about the freedom of the Communes, self-determination, etc. Their battle-cry must be ‘the revolution in permanence.’”

This Address of Marx, written in 1850, appears to be the guide of the Bolsheviks and Spartacists.

The working classes may, however, not expect their immediate emancipation from their political victory.

“In order to work out their own emancipation, and with it that higher form of life which present-day society inevitably opposes, the protracted struggle must pass through a whole series of historical processes, in the course of which men and circumstances alike will be changed. They have no ideal to realise; they have only to set free the elements of the new society, which have already developed in the womb of the collapsing bourgeois society.” — (Marx, “Civil War in France.”)

The means of production will gradually be socialised, production will be placed on a co-operative basis, education will be combined with productive work, in order to transform the members of society into producers. So long

as the transition period lasts the Communist maxim, “From each according to his capacity, to each according to his needs,” cannot become operative. For this period is in every respect — economic, social, and intellectual — still tainted with the marks of the old society, and “rights cannot transcend the economic structure of society, and the cultural development which it determines.” — (Criticism of Gotha Program.) To each will be given according to his deeds.

“Accordingly the individual producer will receive back what he gives to society, after deductions for government, education, and other social charges. He will give society his individual quota of labour. For example: the social working day consists in the sum total of individual working days; the individual labour time of the individual producer is the part of the social working day which he contributes; his share thereof. He will receive from society a certificate that he has performed so much work (after deducting his work for social funds), and with this certificate he will draw from the social provision of articles of consumption as much as a similar quantity of labour costs. The same quantity of labour as he will give to society in one form he will receive back in another.... The right of producers will be proportionate to the work they will perform: the equality will consist in the application of the same measure: labour.”

Because performances will vary in accordance with unequal gifts and degrees of diligence, an unequal distribution will actually take place during the transition period. Only in a fully developed Communistic society, after the distinction between intellectual and physical labour has disappeared, when productive activity has become a first need of life, when the all-round development of the individual and the productive forces has been achieved, and all the springs of co-operative riches flow abundantly; only then can the narrow middle-class idea of rights be improved on, and the Communist principle of equality be put into operation.

Marx, who reasoned on strictly economic lines, and placed the emancipation of the working class as the highest goal, to which all other political and economic movements are subordinated, did not mistake the economic, political, and historical rôle of the nation: this is shown by the Communist Manifesto, where the creation of the national State by the bourgeoisie is indicated. He mocked at the young enthusiasts who thought they could brush aside the nation as an obsolete prejudice, but, in spite of this, he considerably under-estimated the unifying force of national feeling,

considered from a biological and cultural point of view. He divided civilised mankind into antagonistic classes, and assumed that the economic dividing lines would prove to be more effective than national and political boundary lines. He was, therefore, through and through international. Marx demanded that the national Labour Parties should act internationally as soon as there was a possibility of the collapse of the capitalist domination. He reproached the original Gotha program with the fact that “it borrowed from middle-class Leagues of Peace and Freedom the phrase of the international brotherhood of peoples, whereas it was necessary to promote the international combination of the working classes in a common struggle against the ruling classes and their Governments.” Marx had no confidence in the pacifism of the bourgeoisie.

IV. Outlines of the Economic Doctrines.

1. *Capital*.

As we already know, Marx became a Socialist in the year 1843. As a believer in dialectics, he knew that Socialism can only be understood by a knowledge of the movement operating in middle-class society and its developing forces. His investigations in 1843-4 led to the result that political economy forms the basis of bourgeois society. Henceforth political economy became the chief department of his studies. His comprehensive studies of French and English economists, especially Sismondi and Ricardo, and the anti-capitalist literature of England of the years 1820-40, which were connected with the Ricardian theory of value, furnished him with a wealth of suggestions and materials for the criticism of political economy, for the source and origin and development and decline of capitalism, written from the standpoint of the working class and the coming Socialistic society. Such a work is “*Capital*.” It consists of three volumes. Only the first volume (1867) was carried through the press by Marx himself. The other two volumes he only sketched, and they were completed and published by Engels after Marx’s death.

The first volume deals with the origin and tendencies of large industrial capital, with the immediate and simple process of commodity production, so far as it concerns the relations between employer and worker, the exploitation of the proletariat, wages and labour time, and the influence of

modern technique on the condition of the worker. We see in the first volume the effect of the factory system in creating capital. Its chief figure is the producing, suffering, rebellious working class. In the second volume, the employer appears on the market, sells his commodities, and sets the wheels of production again in motion, so that commodities will continue to be produced. In the third volume, the realisation process of the undertakings of the capitalist class, or the movement of capital as a whole is exhibited: cost of production, cost price, total gains and their division into profit, interest and ground rent. The first volume presents the greatest difficulties. The tremendous efforts of the author to produce a masterpiece unnecessarily refined and sublimated and overloaded with learning the doctrines of value and surplus value until they attained the level of a philosophy, an example of Hegelian logic. He played with his subject like an intellectual athlete. That Marx could handle complicated economic questions in a clear, vigorous manner is shown by the third volume, which is written just as it came out of the author's head, and without the apparatus of learning subsequently erected, without the crutches of notes and polemico-philosophical excursions.

To understand "Capital" it is necessary to bear in mind that (1) Marx regarded the scientifically discovered principles as the real inner being of things, practice he regarded as the superficial appearance of things, capable of being apprehended empirically; for example, Value is the theoretical expression, Price the empirical; Surplus Value is the theoretical, and Profit the empirical expression; the appearances apprehended by experience (Price and Profit) deviate indeed from theory, but without the theory they cannot be understood; (2) he looked at the capitalist economic system as being essentially free from external hindrances and disturbances, free from invasions both by the State and the proletariat: the Labour struggles of factory protection laws of which Marx speaks in "Capital" serve rather to perfect the productive forces than to restrict the exploiting proclivities of sovereign capital.

2. Value.

The life and motion of capitalistic society appears as an infinite net of exchange operations, formed out of numerous entwined meshes.

Through the medium of money, men continually exchange the most varied commodities and services. A ceaseless buying and selling, an

uninterrupted series of exchanges of things, and labour power — this constitutes the essential part of human relations in capitalistic society. An economic map of these relations, graphically displayed, would not be less confusing than an astronomical map which exhibited the manifold and intersected orbits of the heavenly bodies. And yet there must be some rule or law which operates in this seeming medley of movements; for men do not work or exchange their goods by hazard, like savages who give their entire lumps of gold or rough diamonds for a necklace of glass pearls. The English and French economists in the seventeenth, eighteenth, and nineteenth centuries, amongst whom Petty (1623-87), Quesnay (1694-1759), Adam Smith (1723-96), and Ricardo (1772-1823) were the most original, sought for the laws which regulated exchange operations, and their theories were designated by Marx as classical bourgeois economy. Following up their investigations, Marx declared: Every commodity, that is, every thing or good produced under Capitalism and brought to the market possesses a use value and an exchange value.

The use value is the utility of the commodity to satisfy a physical or mental need of its user: a commodity without use value is not exchangeable or saleable. As use values, commodities are materially different from each other; nobody will exchange a ton of wheat for a ton of wheat of the same kind, but he will for clothes.

In what measure will commodities exchange with one another? The measure is the exchange value, and this consists in the trouble and quantity of labour which the production of a commodity costs. Equal quantities of labour are exchanged with each other on the market. As exchange values, as the embodiment of human labour, commodities are essentially equal to each other, only quantitatively are they different, as different categories of commodities embody different quantities of labour. It is obvious that the quantities of labour will not be calculated according to the working methods of the individual producers, but according to the prevailing social working methods.

If, for example, hand-weaver A requires twenty hours for the production of a piece of cloth, which in a modern factory will be produced in five hours, the cloth of the hand-weaver does not therefore possess four-fold exchange value. If hand-weaver A demands of consumer B an equivalent of twenty working hours, B answers that a similar piece of cloth can be produced in five hours, and therefore it only represents an exchange value

of five working hours. Thus, according to Marx, the exchange value of a commodity consists in the quantity of socially necessary labour power which its reproduction would require.

This quantity of labour is no constant factor. New inventions, improvements in labour processes, increase in the productivity of labour, etc., cause a diminution in the quantity of labour necessary for the reproduction of a commodity; its exchange value, or expressed in terms of money, its price, will therefore sink, provided that other things (demand, medium of exchange) remain equal.

Consequently, labour is the source of exchange value, and the latter is the principle which regulates exchange operations. Exchange value even measures the extent of the commodity wealth of society. Wealth may increase in volume, but decrease in value, in so far as a less quantity of socially necessary labour becomes necessary for its reproduction.

The more progressive a country is industrially and the higher the level of its civilisation, the greater is its wealth, and the smaller is the quantity of labour which must be expended on the creation of wealth. In the practical Labour politics of our times, this is expressed in higher wages and shorter working hours.

It was said above that use value is a basic condition for the exchange of the individual commodity. This does not exhaust the rôle of use value. The quantity of use value of which society has need determines the quantity of the exchange values to be created. If more commodities are required than society requires, the superfluous commodities have no exchange value, in spite of the labour that is expended on them. — (“Capital” (German), Vol. III., 1, pp. 175-176.)

The complete realisation of exchange values or the social labour that is performed depends, as is seen, on the adaptation of supply to demand, and is a matter of organisation, of social direction.

We have noticed that the Marxian theory of value is related to that of the classical economists, but they are by no means the same thing. Apart from some improvements and definitions which Marx made, they are distinguished by the following conceptions: In the classical theory of value, the capitalist who directs production and provides with his capital the tools and raw materials of labour, markets the finished commodity, and keeps going the processes of reproduction, appears as the only creator of value: the wage worker is only one of his means of production. In the Marxian

theory of value, on the other hand, the wage worker who transforms the raw materials into commodities, or removes the raw materials to the place of production, appears as the sole creator of value. Value is only created by the worker in production, and in distribution connected therewith.

3. *Wages and Labour.*

The worker appears to receive wages for his work. In reality he receives wages as the equivalent for the labour power expended by him, quite in accordance with the law of value, inasmuch as he receives by way of exchange as much means of sustenance as is usual and customary to replace the labour power he has expended, just as the working horse receives as much oats and hay as are necessary to maintain it capable of work.

The capitalist and the worker exchange certain quantities of commodities in proportions determined by economic laws (means of subsistence against a quantity of the commodity, labour power, of equal value, commodity for commodity, exchange value for exchange value).

As, therefore, the wages of labour signify a certain quantity of the means of subsistence, so they increase even if their money form remains unaltered with a fall in the price of the means of life, for the worker is then in the position, with his unaltered wage, to buy a greater quantity of the means of life. In the reverse case, if the prices of the means of life rise, the wages of labour fall, even if their money form remains the same as previously. This law of wages, formulated by Ricardo, was accepted by Marx, but he did not content himself with this acceptance. Ricardo regarded the capitalist world as the only possible and reasonable one, at least at the time when he wrote his “Principles,” while Marx from the year 1843 adopted a critical attitude towards it, and sought to negate it. Consequently, he investigated further, and expressed himself somewhat as follows:

The capitalist theorists believed that the wages question was disposed of when it was settled by the law of value. We know, however, that every commodity possesses not only an exchange value, but also a use value, and is bought for the sake of the latter. The use value of the commodity labour power is distinguished in a very remarkable way from the use value of all other commodities.

The use or the employment of labour power creates exchange value, and can create much more exchange value than itself possesses.

The employer can make use of labour power so long that it not only creates its own exchange value (the value of the means of subsistence), but double this. To create the value of wages, the worker needs five or six hours daily, but he is obliged to produce for the capitalist during ten or twelve hours. If the worker were independent he would only produce during one half of the working day in order to receive his means of subsistence. This period of producing Marx called “necessary labour.” As he is dependent on the capitalist, the worker must not only perform “necessary labour” but also surplus labour: the worker can generally only find employment under the conditions that, besides the time needed for himself, he also works a definite number of hours for the capitalist without payment. Or, as Marx says: “The fact that half a day’s labour is necessary to keep the labourer alive during the 24 hours, does not in any way prevent him from working the whole day. Therefore, the value of labour power and the value which labour creates in the labour process are two entirely different magnitudes. And this difference in the two values was what the capitalist had in view when he was purchasing labour power. The circumstance that on the one hand the daily sustenance of labour power costs only half a day’s labour, while on the other hand the very same labour power can work during a whole day; that consequently the value which its use during one day creates is double what he pays for that use, this circumstance is, without doubt, a piece of good luck for the buyer, but by no means an injury to the seller.”

“No injury to the seller,” which is quite correct from the standpoint of Ricardo, but not from that of Marx. He often calls surplus value “unpaid labour,” and says, for example, “the capitalist appropriates one half of every day’s labour without payment.” In other words, he takes away something without return. This is a very distinct ethical judgment.

On the other hand, it is very important that in our consideration of the wages question we have come up against the Marxian doctrine of surplus value. For this doctrine is the cornerstone of the whole economic system of Marx.

4. Surplus Value.

We have already noted that Marx followed the classical economics in his treatment of the theory of value, but improved the definition of it, and brought it to bear on wages. In doing this he laid stress on the conflict between Capital and Labour.

The beginning of this dialectical process, so far as England was concerned, was the work of the anti-capitalistic critics, who uttered their protest about 1820, or three years after the appearance of Ricardo's work. They declared, according to Ricardo, labour is the source and the measure of value. And yet according to his opinion labour is nothing and capital everything.

This should be reversed: labour must be all, and capital nothing. This literature was contemporaneous with the emergence of the English revolutionary Labour movement, from which Chartism arose at a later date. Piercy Ravenstone (1821) called capital a metaphysical (airy, impalpable) entity. Hodgskin (1827) called it a fetish, whereas they described labour as the economic reality. The expressions surplus-product and surplus-value were already known to this anti-capitalist school, with which Marx also connected himself when he set to work to elaborate his criticism of political economy.⁷ But this literature supplied him with much less material for the construction of the theory of surplus value than the formulation of the theory of value of the classical economy. Besides, while the English anti-capitalist critics, like Ravenstone, Gray, Hodgskin, and J.F. Bray merely condemned surplus value as immoral and as the source of all social wrongs, Marx used the theory of surplus value as the key to unlock the mechanism of the capitalist system and to reveal its workings, its tendencies, and its final destiny. This appears to be the real difference between the English anti-capitalist critics and Marx. In this matter he was obliged to perform most of the work himself. The question he put was no longer "What is the substance of wealth and how is it measured?" but "How is its growth and continual accretions to be explained?" Capital is that portion of wealth which is employed for the purpose of gain, of increase. Whence comes this gain, this increase? The answer is as follows:

All capital that is embarked on a productive undertaking consists of two parts: one part is expended on the technical means of production — on buildings, machines, tools, and raw materials, the other on wages. The first part Marx calls Constant Capital (c), the other part Variable Capital (v). The first is called constant, because it only adds to the commodities just as much value as it loses in the course of the productive process; it creates no fresh value: Marx also calls it the passive portion. The outlay on wages is called variable capital because it undergoes an alteration in the process of

production: it creates new additional value: Marx also called variable capital the active portion, for it creates surplus value (s).

This composition of capital of constant and variable parts Marx calls its organic composition. He calls it average or normal composition when the capital of a business is 80 per cent. constant and 20 per cent. variable. If the constant part is higher, and the variable part lower, he calls it capital of a high composition.

Capital of under 80 per cent. constant portion and over 20 per cent. variable portion he calls capital of a lower composition. And rightly, because the higher the ladder of capitalist production is, the more costly and extensive are the machinery and factory buildings and the greater is the outlay on raw materials, whereas primitive businesses employ less machinery, cheaper workshops, but a relatively greater number of workers. The relation between (c) and (v) reveals at the same time the stage to which production has developed.

Thus, according to Marx, it is solely the variable capital which creates surplus value, or, as it is commonly expressed, profit. We have seen above, in the explanation of the nature of wages, why variable capital creates more value than it is paid for by the capitalist; the worker does indeed receive the exchange value of his labour power, but the use value of the labour power functions, we have assumed, twice as many hours as are necessary for its reproduction. This surplus labour is embodied in surplus value. While the worker receives, let us say, a daily wage of three shillings, for the reproduction of which five hours of work suffice, his labour power will be used for ten hours. These five hours of surplus labour appear in the exchange value of the commodity, so that the value of the commodity is composed of the transferred portion of the constant capital, the outlay on wages, and the added surplus value. Immediately before the production process only constant and variable capital existed, or, in brief (c) and (v); after the completion of the production process, the commodity embodies constant and variable capital and also surplus value, or (c) and (v) and (s). This is the actual value of the commodity, (c) or, shortly expressed, $c + v + s$.

The relation between wages and surplus value, or between paid and unpaid labour, or, shortly, s/v , Marx calls the rate of surplus value: it expresses the degree of the exploitation of labour.

If wages amount to three shillings, which can be produced in five working hours, and if the worker works in the factory ten hours for these wages, so that he creates exchange value to the amount of six shillings, then the rate of surplus value is 100 per cent. The whole of the surplus value which arises in this manner in the process of production is called the mass of the surplus value, or shortly, m.s., that is to say, the individual rate of surplus value multiplied by the total number of workers engaged in an undertaking, or the total amount of wages.

5. Profit.

The mass of surplus value appears to the capitalist in the shape of profit. Surplus value is a Marxian scientific term which exactly expresses the principle of profit. Profit is a commercial expression which describes surplus value as it appears in practical life as a subject of experience, i.e., empirically.

The distinction between the Marxian theoretical and the commercial empirical conception is, however, not so simple: it arises from the different conceptions of the influence of capital and labour in the economic process. Let us explain it more distinctly.

As is known, Marx divided the capital embarked in industrial enterprise into two parts: into constant (technical means of production) and variable (living labour power, wages). He assumed that only the living labour power (wage labour) creates surplus value, whilst the constant capital only adds its own value to the new products.

The capitalist divides his capital outlay otherwise: into fixed (buildings and machines) and circulating (raw materials and wages) capital. The fixed capital is only used up slowly and only passes entirely into production during a series of years — let us say 15 years: thus of a fixed capital of £75,000, £5,000 would each year be consumed in the production of commodities, and written off in the balance sheet. On the other hand, the circulating capital (raw materials and wages) are wholly consumed in every period of production, and must be renewed at the beginning of a new period of production.

Suppose an industrial undertaking about to be started requires a capital expenditure of £105,000: £75,000 fixed capital (for buildings and machinery), £20,000 for raw materials, £10,000 for wages. For convenience sake, we will suppose that the period of production lasts a year, and that the

rate of surplus value amounts to 100 per cent., that is, the labour power receives a payment of £10,000, and produces a value of £20,000. At the end of the year, the capitalist reckons an expenditure of £5,000 on account of fixed capital, and £30,000 of circulating capital: the commodities produced cost, therefore, a net outlay of £35,000. This is the cost price, without adding profit. According to Marx, cost price signifies (c) and (v), therefore without (s), (surplus value).

But the capitalist knows that the manufactured commodities represent a greater value than the cost price. According to Marx, the surplus value amounts to £10,000 (as the variable capital of £10,000 creates surplus value at the rate of 100 per cent.); but the capitalist adds to the cost price a profit which includes the gains of the enterprise and interest on the capital outlay. If the capitalist were alone in the market, his profit might suck up the whole of the surplus value of £10,000; but he has to reckon with competition and the state of the market. The cost price, plus profit, is the production price as established by the capitalist. But according to Marx, that is, in pure theory, the production price is equal to the cost price, plus surplus value. There is thus a quantitative distinction — a difference in the amount of money — between the theoretical and practical production price, as well as a qualitative distinction between the notions of the capitalist and Marx respecting the source of profit. The capitalist believes that profit is the result of the portion of capital which he has put into the process of production, combined with his own commercial ability. On the other hand, Marx asserts that the capitalist can only extract a profit because the wage workers (the living labour power) create a surplus value in the process of production for which they receive no payment.

We assumed that the surplus value amounted to 100 per cent. measured with variable capital, and that £10,000 expended on wages produced £20,000. The annual balance sheet, however, would show the percentage of profit to the total outlay. Consequently, we must spread the £10,000 surplus value over the £35,000 which have been expended. The surplus value of an undertaking spread over the total capital (c) Marx calls the rate of profit, or shortly, $s/c = 10000/35000 = 28.58$ per cent.

As a rule, the capitalist cannot sell under cost price without becoming bankrupt, but he can quite easily sell under the production price, and mostly does so. In the example already given, his rate of profit amounts to over 28 per cent. According to the degree of competition, or by reason of other

circumstances which we will examine in the next chapter, he can content himself with a rate of profit of 10, 15, or 20 per cent., which will serve him partly as an income and partly be expended in the development of his enterprise. The 28 per cent. profit generally forms a circle within which he fixes his manufactured price. Under favourable circumstances he can add the whole 28 per cent. to the price; under less favourable, only 20, 15, or 10 per cent. Accordingly, several portions of surplus value remain in the commodities which are not yet realised. What happens to them? The remaining portions of profit or of surplus value fall to the large or small traders who are interposed between producer and consumer, or go in the form of interest to the banking institutions, in the event of the capitalist operating with borrowed money. As the profit is only realised in the process of circulation (in commerce and exchange) and there divided amongst the various economic classes and sections, most people believe that profit arises in commercial transactions. They do not know that the price of a commodity can only be increased in trade because its manufactured price was fixed below its price of production or its value, that is, because the commodities contain surplus value which is only gradually realised in the process of circulation.

The social significance of this doctrine is far-reaching. If it is correct, then all the social sections which are not engaged as manual and brain workers in the process of production, or in the transport of raw material, lead a parasitical life and consume the surplus value which is squeezed by the capitalist class out of the proletariat and appropriated without payment.

Quite otherwise are capitalist ideas. According to them, profit is the result both of the spirit of the enterprise and the ability of the capitalist, added to that portion of the capital which is put into the process of production: the machines and buildings and raw materials which are used up, and the labour power, all of which are bought at their proper exchange value. It is only fit and proper that the trader and moneylender should receive a portion of the profit so created, for they assist in realising the exchange value by bringing the commodities to the consumer, and thus rendering possible the process of production.

Surplus value or profit? Labour or Capital? Behind this question lurks the great class struggle of the modern social order. No wonder the Marxian doctrine of value and surplus value was the occasion for an extensive

controversy, in which the famous problem of the average rate of profit played a great part.

6. The Average Rate of Profit.

According to Marx's doctrine of value and surplus value only variable capital creates fresh value and surplus value. An industrial undertaking of a lower organic composition, which thus employs much variable capital and little constant capital, must consequently create a greater surplus value or more profit than an industrial undertaking of higher composition which may employ the same total capital, but composed of greater constant and smaller variable portions than the former. Let us take two industrial capitals of £35,000 each. One expends £15,000 on the constant elements (machinery, raw materials) and £20,000 on the variable element (wages of labour). The other shows £20,000 constant part and £15,000 variable part. With an equal rate of surplus value — 100 per cent. — the first capital would produce £20,000 surplus value (profit) and the other only £15,000 profit. Experience shows, however, that equal amounts of capital — in spite of temporary differences in profits — tend to produce equal profits. From this, it would appear that it is actually the capital expended and not the labour employed which determines the magnitude of the surplus value (profit), that the concrete results of the capitalist process of production do not confirm the Marxian theory of value, that the facts directly contradict the theory. It was Marx himself who drew attention to this problem. After he had constructed his theory of surplus value in the form of a scientific law, he continued: "This law clearly contradicts all experience based on appearance. Everyone knows that a cotton spinner, who, reckoning the percentage on the whole of his applied capital, employs much constant capital and little variable capital, does not, on account of this, pocket less profit or surplus value than a baker, who relatively sets in motion much variable and little constant capital."

How, then, can the equal rate of profit in the case of capitals of different organic composition be harmonised with the theory of surplus value?

Marx concedes that equal capital sums whose organic parts are unequally employed give an equal rate of profit, although the volumes of surplus value created are different. Two capital sums of £50,000 each, one of which, for example, represents £40,000 constant and £10,000 variable capital, and with a rate of surplus value of 100 per cent. gives £10,000 surplus value, while the other is composed of £10,000 constant and £40,000

variable capital, and with an equal rate of surplus value gives an amount of £40,000 surplus value, will nevertheless yield an equal rate of profit, although theoretically they would be unequal if the rate of surplus value directly determined the rate of profit. In the first case, the rate of profit would amount to 20 per cent. and in the second to 80 per cent. In reality both undertakings yield an equal rate of profit.

How is this explained, according to Marx? By means of competition, the different rates of profit are levelled to a general rate of profit, which is the average of all the various rates of profit. Thus the capitalists do not realise the surplus value as it is created in any particular factory, but in the form of average rate of profit as it is produced by the operations of the total capital of society. The average rate of profit may be lower or higher than the individual rate of profit, for the “various capitalists,” as Marx explains, “so far as profits are concerned, are so many stockholders in a stock company in which the shares of profits are uniformly divided for every 100 shares of capital, so that profits differ in the case of the individual capitalists only according to the amount of capital invested by each of them in the social enterprise, according to his investment in social production as a whole, according to his shares.”

While thus the individual rates of profit do not proportionately coincide with the rates of surplus value, i.e., while the degree of exploitation of the worker in the individual factory, and the volume of surplus value thus individually created, do not directly determine the individual rate of profit, it is the total mass of social surplus value which is the source of the average rate of profit. If the mass of the surplus value be large, the average rate of profit will also be great. Marx says: “It is here just the same as with average rate of interest which a usurer makes who lends out various portions of his capital at different rates of interest. The level of his average rate depends entirely on how much of his capital he has lent at each of the different rates of interest.” The higher the various individual rates of interest, the higher will be the average rate of interest at which his capital has been put out.

The individual price of production signifies, therefore, cost price plus the average rate of profit, and not plus surplus value: it does not necessarily correspond with the total amount of the constant and variable portions of capital employed in an individual enterprise, plus the mass of the surplus value: the prices and magnitudes of value of commodities are not manifestly equal, as Marx has often pointed out. Of course, the total profits

of the capitalist class coincide with the total surplus value extracted from the working class, provided, of course, that the supply of commodities corresponds with the social needs.

Thus the law of surplus value, in spite of all deviations and refractions, holds good in the last resort. "In theory," observes Marx, "it is assumed that the laws of the capitalist mode of production develop freely. In reality, there is always only an approximation."

And the more capitalist production develops, the greater will be the degree of approximation in particular cases, for the progress of Capitalism signifies a continuous increase of constant capital, a more mechanical character being given to industrial processes, and a reduction of variable capital to the necessary minimum, so that the differences in the organic composition of capitalist undertakings become less, thus bringing the average rate of profit and the rate of surplus value nearer to each other.

This indirect and difficult method of realising profits involves the fact that the capitalist does not distinctly observe the exploitation of wage labour practised by him, but he believes that the profit is owing to his own commercial ability.

This difficult section of the outlines of the economic doctrines of Marx can be most fitly concluded by quoting the comprehensive observations of Marx himself upon this subject, which he gives at the end of his book. — ("Capital" (German), Vol. III., 2, pp. 355-6.)

"In a capitalist society, this surplus value or this surplus product (leaving aside accidental fluctuations in its distribution and considering only the regulating law of these fluctuations) is divided among the capitalists as a dividend in proportion to the percentage of the total social capital held by each. In this shape the surplus value appears as the average profit, which in its turn is separated into profits of enterprise and interest, and which in this way may fall into the hands of different kinds of capitalists. Just as the active capitalist squeezes surplus labour, and with it surplus value in the form of profit out of the worker, so the landlord in his turn squeezes a portion of this surplus value from the capitalist in the shape of rent. Hence when speaking of profit as that portion of surplus value which falls to the share of capital, we mean average profit.... Profits of capital (profits of enterprise plus interest) and ground rent are merely particular constituents of surplus value.... If added together, these parts form the sum of the social

surplus value. A large part of profits is immediately transformed into capital.” In this way, capital grows, or, as Marx says, accumulates.

7. Surplus Value as Social Driving Force.

It has been said already that capital is that portion of wealth which is devoted to the object of increasing wealth, of gain, the extraction of profit or surplus value. This object dominates the capitalist class; the desire for surplus value is the leading impulse and principle motive of their activity. Goaded by this desire and exclusively occupied with their special interests, this class unconsciously and unintentionally develops the entire capitalist system and leads it to ever higher and more comprehensive stages.

Surplus value is thus the driving force of the history of modern capitalist society. This principle is rigidly followed out by Marx in his theoretical system, which aims at showing the rise and growth of Capitalism.

The capitalist is no scientific investigator: he is not clear himself whether profit is created by a portion of the capital, or is the result of personal productive forces, but he knows one thing — without living labour power, without the wage worker, his whole capital remains dead and does not increase; all the fixed capital and raw materials are of no use to him so long as they are not set in motion by living labour power and transformed into commodities. His efforts are, therefore, primarily directed to making proper use of the living labour power. Historically considered, little constant and relatively much variable capital was employed in the primitive stage of the large scale industry: there was as yet little machinery, and the chief thing was the living labour power. The workers were not yet factory proletarians in the modern sense, but artisans who had lost their independent existence.

The capitalist harnessed them and utilised their labour power and special ability. Consequently, he strives to lengthen the working day, in order that as many commodities and as much profit as possible may be produced.

If previously the wage worker had laboured ten hours, of which five were devoted to the production of the value of his wages and five to surplus value, he is now obliged to work for twelve hours, which increases the period for surplus labour to seven hours. The surplus value which is extracted through the lengthening of the working day is called by Marx “absolute surplus value.”

Meanwhile, the capitalist learns by experience that if the workers are so organised as to co-operate with one another, the productivity of labour

increases. From this arises the mode of labour which Marx calls Co-operation, or a reorganisation of the workplace, which raises the entire production of commodities to a higher level. The co-operation of the workers in the process of production soon leads to the discovery that, if the worker does not himself create the whole product, but only a part thereof, he loses less time and becomes quicker and more skilful in his work and produces more than previously. This discovery leads to the “division of labour,” which indeed reduces the worker to the position of an automaton, or a living machine, but considerably augments commodity wealth. Division of labour again demands finer tools; mechanical problems arise to be solved by mechanics and engineers. This favours the progress of mechanics. The growing commodity wealth, and the pressure to realise it profitably, renders necessary more extensive markets; the need for extension comes up against transport difficulties; transport problems arise, to be solved by road and canal engineers. The increasing variety of the labour process and the categories of commodities which are produced results in new metallurgical, physical, and chemical problems. Natural science flourishes.

Meanwhile, things are not so peaceful in the places of manufacture. The lengthening of labour the closer strain on their nerves and muscles, as well as the arrangement of the work, cause the workers to combine and struggle for improved conditions of labour. This struggle, together with the progress of natural science, of technology, and the expansion of markets, result in the discovery of machine technology, of steam and electricity, the foundation of large-scale industry.

The capitalist is impelled, on the one hand, to make himself as independent as possible of living labour-power; on the other hand, to increase the volume of his profits. The means thereto are offered him by the new technical discoveries. Those workers who still possessed some pride in handicraft, or as expropriated small peasants were not able to submit to factory discipline, and showed themselves rebellious, were partly replaced by the labour of women and children, and partly curbed and made pliable. The labour time is repeatedly lengthened, and the exploitation of the labour of women and children assumes terrible proportions. The wage worker, who entered into the manufacturing premises of the employer full of the pride of his calling and often with his own tools, became then a small cog in a gigantic, relentless piece of working machinery.

In this extensive and hitherto unprecedented social transformation the old forms of handicraft disappear: whole sections of society, which are the representatives of the disappearing forms of handicraft, sink into poverty, and augment the class of proletarians. The progress of the industrial revolution extends also to agriculture: the greed for surplus value (ground rent) leads to enclosure of common lands by the great landlords, the independent yeomanry is decimated, the small proprietor and small tenant are made proletarians. A transmutation of social classes takes place; the urban population grows rapidly, the country districts are depopulated: out of the revolutionary process the outlines of two classes become more and more distinct: Capitalist and Proletarian.

Both the factory proletariat and the other social sections which adopt a hostile attitude towards Capitalism react against the health-destroying exploitation, and struggle for a normal working day.

The working time is curtailed and bounds are set to the efforts of the capitalist to lengthen the working day and obtain surplus value, but soon the progress of machine technique compels the worker to labour more intensely in the shorter working time: the accelerated movement of the machine determines the pace and necessitates a sharper straining of the nerves. Henceforth, the worker must compress into a working hour as much effort as was previously expended in an hour and a half. The surplus value which is extracted in this way Marx calls “relative surplus value.” The struggle of the workers to secure a shorter working day is a powerful incentive to the manufacturers to perfect their machinery, in order to increase the amount of relative surplus value. The intensification of work or the creation of relative surplus value is one of the most immediate effects and one of the most striking features of advanced Capitalism. The understanding of this new phase is a preliminary condition to the comprehension of the Marxian system. In this matter, Marx goes considerably beyond the anti-capitalist theoreticians who followed upon Ricardo.

What happens when the capitalist observes that the extraction of absolute surplus value comes up against an insurmountable obstacle? He sets himself to fit up his enterprise with the newest and most costly machinery, in order to supplant living labour-power and to work more intensively the living labour-power which he employs.

As, however, less living labour-power brings forth less exchange value and less surplus value, he is obliged to multiply production, in order to

cover the fall in surplus value by a larger mass of commodities: if the single commodity brings him less profit, he produces it in such large quantities that the profit thereon is the same, or even greater, than formerly. The more complicated machinery, the greater quantities of raw materials consumed, and the relatively smaller amount of labour-power signify obviously an alteration in the organic composition of capital: the constant portion (machinery, raw materials) preponderates more and more over the variable portion. If, previously, the composition was 50 per cent. constant and 50 per cent. variable, it becomes now something like 80 per cent.: 20 per cent. At the same time, the initial capital is also increased greatly, as machines and large quantities of raw and auxiliary materials demand such increase of capital. If, for example, the initial capital previously amounted to £100,000, divided into £50,000 constant and £50,000 variable capital, it would now amount to £500,000, comprising £400,000 constant and £100,000 variable. This organic composition signifies: that relatively smaller masses of labour set in motion large masses of technical means of production; labour is more productive because more intense; the sum total of commodities is increased; the profit on single articles is smaller, but the total profit is greater; the reconversion of profits into capital proceeds rapidly.

The scale of production is more and more extended, and the amount of initial outlay becomes ever greater, because only large capitals are capable of creating relative surplus value in sufficient sums to assure a profit on the enterprise and payment of interest, and thus assist the accumulation of capital.

The more extended scale of production is not possible to the less powerful capitalist undertakings. They partly disappear and partly combine in joint stock companies. The first alternative gives rise to the concentration of the means of production in fewer hands, and the second to the centralisation of the means of production. This is the effect of the new organic composition of capital on the capitalist class.

The effect on the working class is not less profound. As long as the hand-worker still played an important part in the works premises, as long as the variable part was superior or equal to the constant part in the organic composition of capital, as was the case prior to and at the beginning of large-scale industry, the accumulation of capital meant an increased demand for wage-labour. The position was changed as Capitalism developed, in the manner just described. Although the mass of capital grows, there is a

relative decrease in the demand for workers. For this growth of capital refers chiefly to the constant part (machinery and raw materials), while there is a relative shrinkage in the variable part; that means the worker is obliged to consume a much greater quantity of raw material than formerly.

And whereas the prices of commodities fall during the phase of the high organic composition of capital, the period of necessary labour (the hours needed for the reproduction of wages) becomes shorter, while the period of surplus labour becomes longer. The great industrial development therefore signifies for the worker: intensive exploitation and relative over-population, a reserve army of labour-power, which is absorbed by industry in times of prosperous trade, and is speedily demobilised when the slump comes. In times of good business the reserve army serves to check the wage demands of the workers regularly employed, and in times of bad trade it serves to depress wages. The outcome for the workers is as follows:

“Within the capitalist system all methods for raising the social productiveness of labour are brought about at the cost of the individual labourer; all means for the development of production transform themselves into means of domination over, and exploitation of, the producers; they mutilate the labourer into a fragment of a man, degrade him to the level of an appendage to a machine, destroy every remnant of charm in his work, and turn it into a hated toil; they estrange from him the intellectual potentialities of the labour-process in the same proportion as science is incorporated in it as an independent power; they distort the conditions under which he works, subject him during the labour-process to a despotism the more hateful for its meanness; they transform his life-time into working-time, and drag his wife and child beneath the wheels of the Juggernaut of Capital. But all methods for the production of surplus value are at the same time methods of accumulation; and every extension of accumulation becomes again a means for the development of those methods. It follows, therefore, that in proportion as capital accumulates, the lot of the labourer, be his payment high or low, must grow worse. Accumulation of wealth at one pole is, therefore, at the same time accumulation of misery, agony of toil, slavery, ignorance, brutality, mental degradation at the opposite pole, i.e., on the side of the class that produces its own product in the form of capital.” — (“Capital” (German), Vol. I., pp. 660-1.)

The result of the capitalist social order is the unfolding of the productive forces, the efflorescence of science, the expansion of material civilisation,

the dividing of society into antagonistic classes, the conferring of economic power on the few, and the enslavement and degradation of the many.

8. *Economic Contradictions. Decay of Society and its Reconstruction.*

As the ripening of the capitalist social order to its highest point proceeds, its innate contradictions develop, and announce distinctly the fact that Capitalism has outlived its usefulness, while new life, a higher form of society, is emerging from its womb. The most important contradictions are:

The driving force of the capitalist is to obtain the largest measure of surplus value or profit. The latest stage of Capitalism is, however, marked by the fact of the high organic composition of capital, which means that living labour-power, the source of surplus value, has relatively decreased. The decrease of variable capital signifies manifestly a lower rate of profit. Capitalism in normal times exhibits a tendency towards a lowering of the rate of profit. Therefore it gives rise to a phenomenon which contradicts the aim of the endeavours of the capitalists. The capitalist strives to accumulate capital, but as variable capital and the rate of profit relatively decrease, a tendency towards the depreciation of capital is revealed. The capitalist endeavours to counteract this tendency, and to achieve his object by extending the scale of production, so that the mass of commodities will compensate him for what he loses on them singly. But while he furthers this object by resorting to a higher organic composition of capital, he squeezes out the middleman, reduces the numbers of workers in employment, and creates a relative over-population, a reserve of those who are only employed intermittently; there is a substantial shrinkage in the demand for commodities, as the impoverished masses of the people have obviously less purchasing power. The capitalist extends production, and at the same time contracts the market. The upshot is over-production, under-consumption — crisis: wasting of capital, restriction of production, paralysis of the productive forces. And if Marx lived to-day he would add: the developed economy of large-scale capitalism, that is, the high organic composition of industrial capital, requires enormous quantities of raw materials, which, in part, are only to be had from tropical and sub-tropical countries, and also from eastern Asia; the struggle for these sources of raw materials, and for access to them, leads to wars in which capital sums of unprecedented amount are destroyed. Since 1894 these wars over raw materials and trade routes have broken out every few years. Economic crises and imperialist

wars; immeasurable destruction of capital and productive forces. This is a consequence which stands in sharp contradiction to the historical task of the economic order of Capitalism, and to the immediate aims of the individual capitalists.

Further, the capitalist tries from the beginning to create docile and unresisting masses of workers, and yet unites and combines them by the creation of large centres of production; the factories become centres for the organisation of the workers, and for the welding of the individual wills of the proletarians into a class will; they abolish the scattered and antagonistic interests of single sections of the workers, and consolidate them into a unified class interest. Finally, the whole economic process, which began by resting on individualist principles, has assumed a common character; thousands upon thousands of hand and brain workers engage in production in economic undertakings upon a single and uniform plan, with the aid of productive implements which can only be used in common.

The significance and tendency of these contradictions are sketched by Marx in the great finale, which properly belongs to the concluding chapter of the third volume:

“As soon as this process of transformation has sufficiently decomposed the old society from top to bottom, as soon as the labourers are turned into proletarians, their means of labour into capital, as soon as the capitalist means of production stands on its own feet, then the further socialisation of labour and further transformation of the land and other means of production into socially exploited, and therefore common means of production, as well as the further expropriation of private proprietors, takes a new form. That which is now to be expropriated is no longer the labourer working for himself, but the capitalist employing many labourers. This expropriation is accomplished by the action of the immanent laws of capitalist production itself, by the centralisation of capital. One capitalist always kills many. Hand in hand with this centralisation, or this expropriation of many capitalists by a few, develop on an ever-extending scale the co-operative form of the labour process, the conscious technical application of science, the methodical cultivation of the soil, the transformation of the instruments of labour into instruments of labour only usable in common, the economising of all means of production by their use as the means of production of combined, socialised labour, the entanglement of all peoples in the net of the world market, and with this, the international character of

the capitalist regime. Along with the constantly diminishing number of the magnates of capital, who usurp and monopolise all advantages of this process of transformation, grows the mass of misery, oppression, slavery, degradation, exploitation; but with this, too, grows the revolt of the working class, a class always increasing in numbers, and disciplined, united, organised by the very mechanism of the process of capitalist production itself. The monopoly of capital becomes a fetter on the mode of production, which has sprung up and flourished along with it, and under it. Centralisation of the means of production and socialisation of labour at last reach a point where they become incompatible with their capitalist integument. This integument is burst asunder. The knell of capitalist private property sounds. The expropriators are expropriated.” — (“Capital,” Vol. I. English edition, chap. 84.)

ENDNOTES.

CONCLUSION.

An appreciation of Marx can only be arrived at by adopting the Marxian method. We must judge him in the same way as any other towering figure in the realm of thought or of action. Marx was a child of his time, and his system is a logical conception of certain economic and social phenomena of his age, owing something to the pioneer work and thinking of some of his predecessors.

Two important events dominated his thinking: the French Revolution and the English Industrial Revolution. Even apart from the statement of Arnold Ruge that in 1843-44 Marx had collected a vast amount of material for a history of the French National Convention, we know from the work he did between 1844 and 1852 how profound was the influence of the French Revolution on his intellectual life. Still deeper, however, were the traces left upon his mind by the studies he made on the economic transformation of England during the period 1700-1825. Both events are obvious, catastrophic expressions of class movements and class conflicts, in which the middle class, as the representative of a higher economic order, gains the victory over autocratic forms of feudal authority and oligarchic systems of organisation through State regulation, in which, however, at the same time, a new class — the working class — raises its head and begins to make a stand against the victor.

Marx was led to interpret these events in this way and to make them the basis of his conception of history chiefly through the influence of Hegel, Ricardo, and the English anti-capitalist school following upon Ricardo. To the end of his life he clung to the opinion that dialectic, as Hegel had formulated it, was indeed mystical but, when materialistically conceived, contains the laws of the movement of society. “The mystification which dialectic suffers in Hegel’s hands in no wise hinders him from presenting in a comprehensive and intelligible manner its general processes.” — (Preface to second German edition of “Capital,” 1873.)

The splitting up of the concept into contradictories, and the attainment of a higher positive through the negation of these contradictories, that was what, to Marx’s mind, constituted the essence and the deepest meaning of the French Revolution and of the English Industrial Revolution. Society, the positive, split up into feudal and bourgeois, into two sharply divided contradictories, the bourgeoisie appearing as the negation, to be supplanted

by the proletariat and so to make room for a Communist society, the higher synthesis.

What he got from Hegel in a mystical form found an economic expression in Ricardo and the anti-capitalist school. Ricardo's writings, which belong to the second decade of the nineteenth century and which formulate, in the guise of a system of economics, the antagonisms and the conflicts between industry and landed nobility, presented themselves as a practical demonstration of the validity of dialectic. The fundamental idea of Ricardo's system may be expressed as follows:

Capital is the motive force of society and the creator of civilisation, but the fruits of its activity are enjoyed not by capital but by the landed nobility. That is the thesis; now for the proof. The value of all commodities which can be made in any quantity desired consists in the quantity of labour which is expended for the purpose of producing them. The value is expressed in the costs of production, the most important components of which are wages and profit. Wages and profit stand in opposition to one another: if wages rise, profit falls, and conversely. Wages consist in a definite quantity of the necessaries of life, sufficient to keep the worker effective. Wages must obviously rise whenever the cost of living rises. The facts show that this is actually the case. The following reasons make this clear. In consequence of the civilising effects of capital, there is an increase in the opportunities for work and in population, resulting in an increased demand for the necessaries of life. Agriculture must be extended, but agricultural land is limited and of varying quality. The extension of agriculture brings into use the inferior kinds of land, which demand a greater amount of labour for their cultivation. And as the amount of labour determines the value of the commodity, the cost of living increases, and there is a rapid rise in ground rents. The workers demand higher wages, whereby the profits of the employers are diminished. But there is still another circumstance to be taken into consideration. Whereas the prices of agricultural products rise, those of industrial products fall, since, in consequence of the invention of machinery and of the superior division of labour, smaller quantities of labour are required to produce manufactured goods. The result of the entire working of capital for the civilised community is accordingly the reduction of profits, the depreciation of capital, and the increase of wages. This latter, however, is of no advantage to the workers, for food prices rise higher and higher; on the contrary, the whole advantage falls to the landed nobility,

who do nothing for the furtherance of civilisation, but who, through ground rents and protective tariffs, receive everything.

We have, then, in Ricardo a system of economic contradictions between profit, wages, and rent, or between bourgeoisie, proletariat, and nobility, in which the antagonism between bourgeoisie and proletariat is still undeveloped.

The year of the publication of Ricardo's "Principles" (1817) is the year which witnessed the rise of English Socialism. In that year, Robert Owen, in a public meeting in the City of London, declared himself a Socialist. Three years later appeared the first criticisms of Ricardo's political economy. In these it was argued that, according to Ricardo, labour is the source of value, yet he considers capital as the creative factor of society and the working class as a mere appendage of capital. It must be the reverse; for the workers create values together with the surplus products which are appropriated by capital. In 1817, Robert Owen openly declares himself a Socialist; four years later appears the anonymous letter to Lord John Russell; Percy Ravenstone publishes his "Criticism of Capitalism," John Gray his Lecture, and Hodgskin his pamphlet on the unproductive nature of capital, in which he establishes the existence of a raging class struggle.

The deep impression which these writings made on Marx is clearly seen in the second and third volumes of his "Theories on Surplus Value." And he links on to them. He completed what Ricardo hinted at and what the anti-capitalist school deduced from Ricardo. How Marx continued and elaborated these deductions we have already seen in Chapter 3, "Outlines of Marx's Economics," and Chapter 7, "Surplus Value as the Motive Force of Society," where capital is shown to be the mass of surplus value of which the workers have been deprived.

The deductions made by the English anti-capitalist school from Ricardo signified, politically, the first awakenings of the English workers to class-consciousness, to the struggle against capital. Just as Ricardo's theory of value and rent was the battle-cry of capital against the aristocracy — a battle-cry which created the free trade movement and shattered the economic power of the landed nobility, so the theory of value and surplus value was to become the battle-cry of the proletariat against the bourgeoisie, the declaration of independence, so to speak, of the working class. The English proletariat lacked a philosopher who could work out the idea to its logical conclusion, until Marx applied himself to the problem and solved it,

so far indeed as philosophical problems can be solved, by a science which places itself at the disposal of a class movement.

For it is impossible to set aside the view that Marx's theory of value and surplus value has rather the significance of a political and social slogan than of an economic truth. It is for Marx the basis of the class struggle of the workers against the middle class, just as Ricardo's theory of rent was the basis of the class struggle of the bourgeoisie against the aristocracy, or as the doctrines of the social contract and of the natural rights of man formed the basis of the struggle of the middle classes against autocracy and divine right. Such militant philosophies need not in themselves be true, only they must accord with the sentiments of the struggling mass. It is with such philosophical fictions that human history works. Marx's theory of value explains neither the vast and unparalleled accumulation of wealth nor the movement of prices during the last sixty years. Wealth, measured in values, has, in the last few decades, increased by many times the increase in living labour-power. In this connection the old formula can be reversed: wealth increases in geometrical, living labour-power in arithmetical progression. The greatest difficulty in Marx is that the inventors and discoverers, the chemists and physicists, the pioneers and organisers of industry and agriculture, are not regarded by him as creators of surplus values. Thinkers, who by chemical researches and discoveries double the productive capacity of the soil and conjure forth values in millions from the waste products of industry: physicists who place new sources of power and new means of production at the disposal of mankind and multiply the productivity of labour; organisers who co-ordinate the forces of production and introduce new methods of working — all this creative and directive work, demanding, as it often does, an infinite amount of intensive intellectual effort, is not considered to increase the total sum of exchange values of the nation.

However, as far as the distribution of products is concerned, Marx's theory is, generally speaking, correct; distribution is carried out under the capitalist economic system not according to the amount of productive work done, but in proportion to the outlay of capital and the skill in commercial manœuvring which obtains in the sphere of circulation.

Unique as an investigator of the laws of the proletarian movement, eminent and even a great pioneer as a sociologist, Marx is, in respect of economic theory, predominantly an agitator. His system, more than any other system of Socialism or of political economy, is the revolutionary

expression of proletarian thought and feeling. His doctrines of value, surplus value, the economic determination of history, the evolution from Capitalism to Socialism, the political and economic class struggle, will for long have the force of truth for the masses and will continue to move them.

Marx's heart must have been filled with joy and gladness when, out of the elements of Hegel, Ricardo, and the English anti-capitalist school, out of his studies of the French Revolution, of the English Industrial Revolution, and of French and English Socialism there arose a unified system whose destiny it was to lead mankind out of the earth-bound history of the past into the new world wherein a spiritual civilisation should fully blossom forth. Man is to quit the realm of necessity and to enter into that of freedom, where he shall cease to be a tool for the profit of others and shall rise to have a purpose of his own, freely associating himself with his fellow men to work in the service of all.

“The realm of freedom, indeed, only begins there where work conditioned by necessity and external utility ceases. According to the nature of the thing, therefore, it lies beyond the sphere of actual material production. Just as the savage must struggle with nature for the satisfaction of his needs, for self-preservation and self-reproduction, so too must the civilised man, whatever be the form of society or the methods of production obtaining. Side by side with his own evolution develops this constitutional necessity, because his needs increase; but, at the same time, the forces of production which satisfy these needs likewise increase. Freedom in this sphere can only consist in this — that men in their social relationship, the associated producers, should regulate this material exchange with Nature in a rational manner and bring it under their united control, instead of being governed by it as by some blind power; it should be carried on with the minimum expenditure of energy and under conditions most adapted to and most worthy of human nature. Yet it remains all the same a realm of necessity. It is beyond this where that development of human power, which may be called independent purpose, begins, the true realm of freedom, which, however, can only flourish upon the basis of that realm of necessity.” — (“Capital,” Vol. III., 2, p. 355.)

BRIEF BIOGRAPHY by Eduard Bernstein

From 1911 Encyclopædia Britannica, Volume 17

MARX, HEINRICH KARL (1818-1883), German socialist, and head of the International Working Men's Association, was born on the 5th of May 1818 in Trèves (Rhenish Prussia). His father, a Jewish lawyer, in 1824 went over to Christianity, and he and his whole family were baptized as Christian Protestants. The son went to the high grammar school at Trèves, and from 1835 to the universities of Bonn and Berlin. He studied first law, then history and philosophy, and in 1841 took the degree of doctor of philosophy. In Berlin he had close intimacy with the most prominent representatives of the young Hegelians — the brothers Bruno and Edgar Bauer and their circle, the so-called "Freien." He at first intended to settle as a lecturer at Bonn University, but his Radical views made a university career out of the question, and he accepted work on a Radical paper, the *Rheinische Zeitung*, which expounded the ideas of the most advanced section of the Rhenish Radical *bourgeoisie*. In October 1842 he became one of the editors of this paper, which, however, after an incessant struggle with press censors, was suppressed in the beginning of 1843. In the summer of this year Marx married Jenny von Westphalen, the daughter of a high government official. Through her mother Jenny von Westphalen was a lineal descendant of the earl of Argyle, who was beheaded under James II. She was a most faithful companion to Marx during all the vicissitudes of his career, and died on the 2nd of December 1881; he outliving her only fifteen months.

Already in the *Rheinische Zeitung* some socialist voices had been audible, couched in a somewhat philosophical strain. Marx, though not accepting these views, refused to criticize them until he had studied the question thoroughly. For this purpose he went in the autumn of 1843 to Paris, where the socialist movement was then at its intellectual zenith, and where he, together with Arnold Ruge, the well-known literary leader of Radical Hegelianism, was to edit a review, the *Deutsch-französische Jahrbücher*, of which, however, only one number appeared. It contained

two articles by Marx — a criticism of Bruno Bauer's treatment of the Jewish question, and an introduction to a criticism of Hegel's philosophy of the law. The first concluded that the social emancipation of the Jews could only be achieved together with the emancipation of society from Judaism, *i.e.* commercialism. The second declared that in Germany no partial political emancipation was possible; there was now only one class from which a real and reckless fight against authority was to be expected — namely, the proletariat. But the proletariat could not emancipate itself except by breaking all the chains, by dissolving the whole constituted society, by recreating man as a member of the human society in the place of established states and classes. "Then the day of German resurrection will be announced by the crowing of the Gallican cock." Both articles thus relegated the solution of the questions then prominent in Germany to the advent of socialism, and so far resembled in principle other socialist publications of the time. But the way of reasoning was different, and the final words of the last quoted sentence pointed to a political revolution, to begin in France as soon as the industrial evolution had created a sufficiently strong proletariat. In contradistinction to most of the socialists of the day, Marx laid stress upon the political struggle as the lever of social emancipation. In some letters which formed part of a correspondence between Marx, Ruge, Ludwig Feuerbach, and Mikhail Bakunin, published as an introduction to the review, this opposition of Marx to socialistic "dogmatism" was enunciated in a still more pronounced form: "Nothing prevents us," he said, "from combining our criticism with the criticism of politics, from participating in politics, and consequently in real struggles. We will not, then, oppose the world like doctrinarians with a new principle: here is truth, kneel down here! We expose new principles to the world out of the principles of the world itself. We don't tell it: 'Give up your struggles, they are rubbish, we will show you the true war-cry.' We explain to it only the real object for which it struggles, and consciousness is a thing it *must* acquire even if it objects to it."

In Paris Marx met Friedrich Engels (1820-1895), from whom the *Deutsch-französische Jahrbücher* had two articles — a powerfully written outline of a criticism of political economy, and a letter on Carlyle's *Past and Present*. Engels, the son of a wealthy cotton-spinner, was born in 1820 at Barmen. Although destined by his father for a commercial career, he attended a classical school, and during his apprenticeship and whilst

undergoing in Berlin his one year's military service, he had given up part of his free hours to philosophical studies. In Berlin he had frequented the society of the "Freien," and had written letters to the *Rheinische Zeitung*. In 1842 he had gone to England, his father's firm having a factory near Manchester, and had entered into connexion with the Owenite and Chartist movements, as well as with German communists. He contributed to Owen's *New Moral World* and to the Chartist *Northern Star*, gave up much of his abstract speculative reasoning for a more positivist conception of things, and took to economic studies. Now, in September 1844, on a short stay in Paris, he visited Marx, and the two found that in regard to all theoretical points there was perfect agreement between them. From that visit dates the close friendship and uninterrupted collaboration and exchange of ideas which lasted during their lives, so that even some of Marx's subsequent works, which he published under his own name, are more or less also the work of Engels. The first result of their collaboration was the book *Die heilige Familie oder Kritik der kritischen Kritik, gegen Bruno Bauer und Konsorten*, a scathing exposition of the perverseness of the high-sounding speculative radicalism of Bauer and the other Berlin "Freie." By aid of an analysis, which, though not free from exaggeration and a certain diffuseness, bears testimony to the great learning of Marx and the vigorous discerning faculty of both the authors, it is shown that the supposed superior criticism — the "critical criticism" of the Bauer school, based upon the doctrine of a "self-conscious" idea, represented by or incarnated in the critic — was in fact inferior to the older Hegelian idealism. The socialist and working-class movements in Great Britain, France and Germany are defended against the superior criticism of the "holy" Bauer family.

In Paris, where he had very intimate intercourse with Heinrich Heine, who always speaks of him with the greatest respect, and some of whose poems were suggested by Marx, the latter contributed to a Radical magazine, the *Vorwärts*; but in consequence of a request by the Prussian government, nearly the whole staff of the magazine soon got orders to leave France. Marx now went to Brussels, where he shortly afterwards was joined by Engels. In Brussels he published his second great work, *La Misère de la philosophie*, a sharp rejoinder to the *Philosophie de la misère ou contradictions économiques* of J. P. Proudhon. In this he deals with Proudhon, whom in the former work he had defended against the Bauers, not less severely than with the latter. It is shown that in many points

Proudhon is inferior to both the middle-class economists and the socialists, that his somewhat noisily proclaimed discoveries in regard to political economy were made long before by English socialists, and that his main remedies, the “constitution of the labour-value” and the establishment of exchange bazaars, were but a repetition of what English socialists had already worked out much more thoroughly and more consistently. Altogether the book shows remarkable knowledge of political economy. In justice to Proudhon, it must be added that it is more often his mode of speaking than the thought underlying the attacked sentences that is hit by Marx’s criticism. In Brussels Marx and Engels also wrote a number of essays, wherein they criticized the German literary representatives of that kind of socialism and philosophic radicalism which was mainly influenced by the writings of Ludwig Feuerbach, and deduced its theorems or postulates from speculations on the “nature of man.” They mockingly nicknamed this kind of socialism “German or True Socialism,” and ridiculed the idea that by disregarding historical and class distinctions a conception of society and socialism superior to that of the English and French workers and theorists could be obtained. Some of these essays were published at the time, two or three, curiously enough, by one of the attacked writers in his own magazine; one, a criticism of Feuerbach himself, was in a modified form published by Engels in 1885, but others have remained in manuscript. They were at first intended for publication in two volumes as a criticism of post-Hegelian German philosophy, but the Revolution of 1848 postponed for a time all interest in theoretical discussions.

In Brussels Marx and Engels came into still closer contact with the socialist working-class movement. They founded a German workers’ society, acquired a local German weekly, the *Brüsseller deutsche Zeitung*, and finally joined a communistic society of German workers, the “League of the Just,” a secret society which had its main branches in London, Paris, Brussels and several Swiss towns. For this league, which till then had adhered to the rough-and-ready communism of the gifted German workman Wilhelm Weitling, but which now called itself “League of the Communists,” and gave up its leanings towards conspiracy and became an educational and propagandistic body, Marx and Engels at the end of 1847 wrote their famous pamphlet, *Manifest der Kommunisten*. It was a concise exposition of the history of the working-class movement in modern society according to their views, to which was added a critical survey of the

existing socialist and communist literature, and an explanation of the attitude of the Communists towards the advanced opposition parties in the different countries. Scarcely was the manifesto printed when, in February 1848, the Revolution broke out in France, and “the crowing of the Gallican cock” gave the signal for an upheaval in Germany such as Marx had prophesied. After a short stay in France, Marx and Engels went to Cologne in May 1848, and there with some friends they founded the *Neue rheinische Zeitung*, with the sub-title “An Organ of Democracy,” a political daily paper on a large scale, of which Marx was the chief editor. They took a frankly revolutionary attitude; and directed their criticism to a great extent against the middle-class democratic parties, who, by evading all decisive issues, delayed the achievement of the upheaval. When in November 1848 the king of Prussia dissolved the National Assembly, Marx and his friends advocated the non-payment of taxes and the organization of armed resistance. Then the state of siege was declared in Cologne, the *Neue rheinische Zeitung* was suspended, and Marx was put on trial for high treason. He was unanimously acquitted by a middle-class jury, but in May 1849 he was expelled from Prussian territory. He went to Paris, but was soon given the option of either leaving France or settling at a small provincial place. He preferred the former, and went to England. He settled in London, and remained there for the rest of his life.

At first he tried to reorganize the Communist League; but soon a conflict broke out in its ranks, and after some of its members had been tried in Germany and condemned for high treason, Marx, who had done everything to save the accused, dissolved the Communist League altogether. Nor was a literary enterprise, a review, also called the *Neue rheinische Zeitung*, more successful; only six numbers of it were issued. It contained, however, some very remarkable contributions; and a series of articles on the career of the French Revolution of 1848, which first appeared there, was in 1895 published by Engels in book form under the title of *Die Klassenkämpfe in Frankreich von 1848* “by Karl Marx.” Carlyle’s *Latter Day Pamphlets*, published at that time, met with a very vehement criticism in the *Neue rheinische Zeitung*. The endeavours of Ernest Jones and others to revive the Chartist movement were heartily supported by Marx, who contributed to several of the Chartist journals of the period, mostly, if not wholly, without getting or asking payment. He lived at this time in great financial straits, occupied a few small rooms in Dean Street, Soho, and all his children then

born died very young. At length he was invited to write letters for the *New York Tribune*, whose staff consisted of advanced democrats and socialists of the Fourierist school. For these letters he was paid at the rate of a guinea each. Part of them, dealing with the Eastern Question and the Crimean War, were republished in 1897 (London, Sonnenschein). Some were even at the time reprinted in pamphlet form. The co-operation of Marx, who was determinedly anti-Russian, since Russia was the leading reactionary power in Europe, was obtained by David Urquhart and his followers. A number of Marx's articles were issued as pamphlets by the Urquhartite committees, and Marx wrote a series of articles on the diplomatic history of the 18th century for the Urquhartite *Free Press* (Sheffield and London, 1856-1857). When in 1859 the Franco-Austrian War about Italy broke out, Marx denounced it as a Franco-Russian intrigue, directed against Germany on the one hand and the revolutionary movement in France on the other. He opposed those democrats who supported a war which in their eyes aimed at the independence of the Italian nation and promised to weaken Austria, whose superiority in Germany was the hindrance to German unity. Violent derogatory remarks directed against him by the well-known naturalist Karl Vogt gave occasion to a not less violent rejoinder, *Herr Vogt*, a book full of interesting material for the student of modern history. Marx's contention, that Vogt acted as an agent of the Bonapartist clique, seems to have been well founded, whilst it must be an open question how far Vogt acted from dishonourable motives. The discussions raised by the war also resulted in a great estrangement between Marx and Ferdinand Lassalle. Lassalle had taken a similar view of the war to that advocated by Vogt, and fought tooth and nail for it in letters to Marx. In the same year, 1859, Marx published as a first result of his renewed economic studies the book *Zur Kritik der politischen Ökonomie*. It was the first part of a much larger work planned to cover the whole ground of political economy. But Marx found that the arrangement of his materials did not fully answer his purpose, and that many details had still to be worked out. He consequently altered the whole plan and sat down to rewrite the book, of which in 1867 he published the first volume under the title *Das Kapital*.

In the meantime, in 1864, the International Working Men's Association was founded in London, and Marx became in fact though not in name, the head of its general council. All its addresses and proclamations were penned by him and explained in lectures to the members of the council. The first

years of the International went smoothly enough. Marx was then at his best. He displayed in the International a political sagacity and toleration which compare most favourably with the spirit of some of the publications of the Communist League. He was more of its teacher than an agitator, and his expositions of such subjects as education, trade unions, the working day, and cooperation were highly instructive. He did not hurry on extreme resolutions, but put his proposals in such a form that they could be adopted by even the more backward sections, and yet contained no concessions to reactionary tendencies. But this condition of things was not permitted to go on. The anarchist agitation of Bakunin, the Franco-German War, and the Paris Commune created a state of things before which the International succumbed. Passions and prejudices ran so high that it proved impossible to maintain any sort of centralized federation. At the congress of the Hague, September 1872, the general council was removed from London to New York. But this was only a makeshift, and in July 1876 the rest of the old International was formally dissolved at a conference held in Philadelphia. That its spirit had not passed away was shown by subsequent international congresses, and by the growth and character of socialist labour parties in different countries. They have mostly founded their programmes on the basis of its principles, but are not always in their details quite in accordance with Marx's views. Thus the programme which the German socialist party accepted at its congress in 1875 was very severely criticized by Marx. This criticism, reprinted in 1891 in the review *Die neue Zeit*, is of great importance for the analysis of Marx's conception of socialism.

The dissolution of the International gave Marx an opportunity of returning to his scientific work. He did not, however, succeed in publishing further volumes of *Das Kapital*. In order to make it — and especially the part dealing with property in land — as complete as possible, he took up, as Engels tells us, a number of new studies, but repeated illness interrupted his researches, and on the 14th of March 1883 he passed quietly away.

From the manuscripts he left Engels compiled a second and a third volume of *Das Kapital* by judiciously and elaborately using complete and incomplete chapters, rough copies and excerpts, which Marx had at different times written down. Much of the copy used dates back to the 'sixties, *i.e.* represents the work as at first conceived by Marx, so that, *e.g.*, the matter published as the third volume was in the main written much earlier than the matter which was used for compiling the second volume.

The same applies to the fourth volume. Although the work thus comprises the four volumes promised in the preface to the book, it can only in a very restricted sense be regarded as complete. In substance and demonstration it must be regarded as a torso. And it is perhaps not quite accidental that it should be so. Marx, if he had lived longer and had enjoyed better health, would have given the world a much greater amount of scientific work of high value than is now the case. But it seems doubtful whether he would have brought *Das Kapital*, his main work, to a satisfactory conclusion.

Das Kapital proposes to show up historically and critically the whole mechanism of capitalist economy. The first volume deals with the processes of producing capital, the second with the circulation of capital, the third with the movements of capital as a whole, whilst the fourth gives the history of the theories concerning capital. Capital is, according to Marx, the means of appropriating *surplus-value* as distinguished from ground rent (rent on every kind of terrestrial property, such as land, mines, rivers, &c., based upon the monopolist nature of such property). Surplus-value is created in the process of production only, it is this part of the value of the newly created product which is not given to the workman as a return — the *wage* — of the labour-force he expended in working. If at first taken by the employer, it is in the different phases of economic intercourse split up into the profit of industrial enterprise, commercial or merchants' profit, interest and ground rent. The value of every commodity consists in the labour expended on it, and is measured according to the time occupied by the labour employed on its production. Labour in itself has no value, being only the measure of value, but the labour-force of the workman has a value, the value of the means required to maintain the worker in normal conditions of social existence. Thus, in distinction to other commodities, in the determination of the value of labour-force, besides the purely economical, a *moral* and *historical* element enter. If to-day the worker receives a wage which covers the bare necessities of life, he is underpaid — he does not receive the real value of his labour-force. For the value of any commodity is determined by its socially necessary costs of production (or in this case, maintenance). "Socially necessary" means, further, that no more labour is embodied in a commodity than is required by applying labour-force, tools, &c., of average or normal efficiency, and that the commodity is produced in such quantity as is required to meet the effective demand for it. As this generally cannot be known in advance, the market value of a commodity

only gravitates round its (abstract) value. But in the long run an equalization takes place, and for his further deductions Marx assumes that commodities exchange according to their value.

That part of an industrial capital which is employed for installations, machines, raw and auxiliary materials, is called by Marx *constant capital*, for the value of it or of its wear and tear reappears in equal proportions in the value of the new product. It is otherwise with labour. The new value of the product must by necessity be always higher than the value of the employed labour-force. Hence the capital employed in buying labour-force, *i.e.* in wages, is called *variable capital*. It is the tendency of capitalist production to reduce the amount spent in wages and to increase the amount invested in machines, &c. For with natural and social, legal and other limitations of the working day, and the opposition to unlimited reduction of wages, it is not possible otherwise to cheapen production and beat competition. According to the proportion of constant to variable capital, Marx distinguishes capitals of *lowest average* and *highest composition*, the highest composition being that where proportionately the least amount of variable (wages) capital is employed.

The ratio of the wages which workmen receive to the surplus-value which they produce Marx calls the *rate of surplus-value*; that of the surplus-value produced to the whole capital employed is the *rate of profit*. It is evident, then, that at the same time the rate of surplus-value can increase and the rate of profit decrease, and this in fact is the case. There is a continuous tendency of the rates of profit to decrease, and only by some counteracting forces is their decrease temporarily interrupted, protracted, or even sometimes reversed. Besides, by competition and movement of capitals the rates of profit in the different branches of trade are pressed towards an *equalization* in the shape of an *average rate of profits*. This average rate or profits, added to the actual cost price of a given commodity, constitutes its *price of production*, and it is this price of production which appears to the empirical mind of the business man as the value of the commodity. The real law of value, on the contrary, disappears from the surface in a society where, as to-day, commodities are bought and sold against money and not exchanged against other commodities. Nevertheless, according to Marx, it is also to-day this law of value ("labour-value") which in the last resort rules the prices and profits.

The tendency to cheapen production by increasing the relative proportion of constant capital — the fixed capital of the classical economist plus that portion of the circulating capital which consists of raw and auxiliary materials, &c. — leads to a continuous increase in the size of private enterprises, to their growing concentration. It is the larger enterprise that beats and swallows the smaller. The number of dependent workmen—“proletarians” — is thus continually growing, whilst employment only periodically keeps pace with their number. Capital alternately attracts and repels workmen, and creates a constant surplus-population of workmen — a *reserve-army* for its requirements — which helps to lower wages and to keep the whole class in economic dependency. A decreasing number of capitalists usurp and monopolize all the benefits of industrial progress, whilst the mass of misery, of oppression, of servitude, of depravation, and of exploitation increases. But at the same time the working class continuously grows in numbers, and is disciplined, united and organized by the very mechanism of the capitalist mode of production. The centralization of the means of production and the socialization of the mode of production reach a point where they will become incompatible with their capitalist integument. Then the knell of capitalist private property will have been rung. Those who used to expropriate will be expropriated. Individual property will again be established based upon co-operation and common ownership of the earth and the means of production produced by labour.

These are the principal outlines of *Das Kapital*. Its purely economic deductions are dominated throughout by the *theory of surplus-value*. Its leading sociological principle is the *materialist conception of history*. This theory is in *Das Kapital* only laid down by implication, but it has been more connectedly explained in the preface of *Zur Kritik* and several works of Engels. According to it the material basis of life, the manner in which life and its requirements are produced, determines in the last instance the social ideas and institutions of the time or historical epoch, so that fundamental changes in the former produce in the long run also fundamental changes in the latter. A set of social institutions answer to a given mode of production, and periods where the institutions no longer answer to the mode of production are periods of social revolution, which go on until sufficient adjustment has taken place. The main *subjective* forces of the struggle between the old order and the new are *the classes* into which society is divided after the dissolution of the communistic or semi-communistic tribes

and the creation of states. And as long as society is divided into classes a class war will persist, sometimes in a more latent or disguised, sometimes in a more open or acute form, according to circumstances. In advanced capitalist society the classes between whom the decisive war takes place are the capitalist owners of the means of production and the non-propertied or wage-earning workers, the “proletariate.” But the proletariat cannot free itself without freeing all other oppressed classes, and thus its victory means the end of exploitation and political repression altogether. Consequently the state as a repressive power will die out, and a free association will take its place.

Almost from the first *Das Kapital* and the publications of Marx and Engels connected with it have been subjected to all kinds of criticisms. The originality of its leading ideas has been disputed, the ideas themselves have been declared to be false or only partially true, and consequently leading to wrong conclusions; and it has been said of many of Marx’s statements that they are incorrect, and that many of the statistics upon which he bases his deductions do not prove what he wants them to prove. In regard to the first point, it must be conceded that the *dissecta membra* of Marx’s value theory and of his materialist conception of history are already to be found in the writings of former socialists and sociologists. It may even be said that just those points of the Marxist doctrine which have become popular are in a very small degree the produce of Marx’s genius, and that what really belongs to Marx, the methodical conjunction and elaboration of these points, as well as the finer deductions drawn from their application, are generally ignored. But this is an experience repeated over and over again in the history of deductive sciences, and is quite irrelevant for the question of Marx’s place in the history of socialism and social science.

It must further be admitted that in several places the statistical evidence upon which Marx bases his deductions is insufficient or inconclusive. Moreover — and this is one of the most damaging admissions — it repeatedly happens that he points out all the phenomena connected with a certain question, but afterwards ignores some of them and proceeds as if they did not exist. Thus, *e.g.*, he speaks at the end of the first volume, where he sketches the historical tendency of capitalist accumulation, of the decreasing number of magnates of capital as of an established fact. But all statistics show that the number of capitalists does not decrease, but increase; and in other places in *Das Kapital* this fact is indeed fully admitted, and

even accentuated. Marx was, as the third volume shows, also quite aware that limited liability companies play an important part in the distribution of wealth. But he leaves this factor, too, quite out of sight, and confuses the concentration of private enterprises with the centralization of fortunes and capitals. By these and other omissions, quite apart from developments he could not well foresee, he announces a coming evolution which is very unlikely to take place in the way described.

In this and in other features of his work a *dualism* reveals itself which is also often observable in his actions in life — the alternating predominance of the spirit of the scholar and the spirit of the radical revolutionary. Marx originally entitled his great social work *Criticism of Political Economy*, and this is still the sub-title of *Das Kapital*. But the conception of *critic* or *criticize* has with Marx a very pronounced meaning. He uses them mostly as identical with fundamentally opposing. Much as he had mocked the “critical criticism” of the Bauers, he is in this respect yet of their breed and relapses into their habits. He retained in principle the Hegelian dialectical method, of which he said that in order to be rationally employed it must be “turned upside down,” *i.e.* put upon a materialist basis. But as a matter of fact he has in many respects contravened against this prescription. Strict materialist dialectics cannot conclude much beyond actual facts. Dialectical materialism is revolutionary in the sense that it recognizes no finality, but otherwise it is necessarily positivist in the general meaning of that term. But Marx’s opposition to modern society was fundamental and revolutionary, answering to that of the proletarian to the *bourgeois*. And here we come to the main and fatal contradiction of his work. He wanted to proceed, and to a very great extent did proceed, scientifically. Nothing was to be deduced from preconceived ideas; from the observed evolutionary laws and forces of modern society alone were conclusions to be drawn. And yet the final conclusion of the work, as already noted, is a preconceived idea; it is the announcement of a state of society logically opposed to the given one. Imperceptibly the dialectical movement of ideas is substituted for the dialectical movement of facts, and the real movement of facts is only considered so far as is compatible with the former. Science is violated in the service of speculation. The picture given at the end of the first volume answers to a conception arrived at by speculative socialism in the ‘forties. True, Marx calls this chapter “the historical tendency of capitalist accumulation,” and “tendency” does not necessarily mean realization in

every detail. But on the whole the language used there is much too absolute to allow of the interpretation that Marx only wanted to give a speculative picture of the goal to which capitalist accumulation would lead if unhampered by socialist counteraction. The epithet “historical” indicates rather that the passage in question was meant to give in the main the true outline of the forthcoming social revolution. We are led to this conclusion also by the fact that, in language which is not in the least conditional, it is there said that the change of capitalist property into social property will mean “only the expropriation of a few usurpers by the mass of the people.” In short, the principal reason for the undeniable contradictions in *Das Kapital* is to be found in the fact that where Marx has to do with details or subordinate subjects he mostly notices the important changes which actual evolution had brought about since the time of his first socialist writings, and thus himself states how far their presuppositions have been corrected by facts. But when he comes to general conclusions, he adheres in the main to the original propositions based upon the old uncorrected presuppositions. Besides, the complex character of modern society is greatly underestimated, so that, e.g., such important features as the influence of the changes of traffic and aggregation on modern life are scarcely considered at all; and industrial and political problems are viewed only from the aspect of class antagonism, and never under their administrative aspect. With regard to the theory of surplus-value and its foundation, the theory of labour-value, so much may be safely said that, its premisses accepted, it is most ingeniously and most consistently worked out. And since its principal contention is in any case so far true that the wage-earning workers as a whole produce more than they receive, the theory has the great merit of demonstrating in an admirably lucid way the relations between wages and surplus-produce and the growth and movements of capital. But the theory of labour-value as the determining factor of the exchange or market value of commodities can with justification be disputed, and is surely not more true than those theories of value based on social demand or utility. Marx himself, in placing in the third volume what he calls the law of value in the background and setting out the formation of the “price of production” as the empirical determinator of prices in modern society, justifies those who look upon the conception of labour-value as an abstract formula which does not apply to individual exchanges of commodities at all, but which only serves to show an imagined typical example of what in reality to-day is only true with

regard to the production of the whole of social wealth. Thus understood, the conception of labour-value is quite unobjectionable, but it loses much of the significance attributed to it by most of the disciples of Marx and occasionally by Marx himself. It is a means of analysing and exemplifying surplus labour, but quite inconclusive as to the proof of the surplus value, or as an indication of the degree of the exploitation of the workers. This becomes the more apparent the more the reader advances in the second and third volumes of *Das Kapital*, where commercial capital, money capital and ground rent are dealt with. Though full of fine observations and deductions, they form, from a revolutionary standpoint, an anti-climax to the first volume. It is difficult to see how, after all that is explained there on the functions of the classes that stand between industrial employers and workers, Marx could have returned to those sweeping conclusions with which the first volume ends.

The great scientific achievement of Marx lies, then, not in these conclusions, but in the *details* and yet more in the *method* and *principles* of his investigations in his philosophy of history. Here he has, as is now generally admitted, broken new ground and opened new ways and new outlooks. Nobody before him had so clearly shown the rôle of the productive agencies in historical evolution; nobody so masterfully exhibited their great determining influence on the forms and ideologies of social organisms. The passages and chapters dealing with this subject form, notwithstanding occasional exaggerations, the crowning parts of his works. If he has been justly compared with Darwin, it is in these respects that he ranks with that great genius, not through his value theory, ingenious though it be. With the great theorist of biological transformation he had also in common the indefatigable way in which he made painstaking studies of the minutest details connected with his researches. In the same year as Darwin's epoch-making work on the origin of species there appeared also Marx's work *Zur Kritik der politischen Ökonomie*, where he explains in concise sentences in the preface that philosophy of history which has for the theory of the transformation or evolution of social organisms the same significance that the argument of Darwin had for the theory of the transformation of biological organisms.

Bibliography. — The main writings of Karl Marx and Friedrich Engels are as follow (we give only the titles of the original works and of their English translations): (1) Of Karl Marx alone: *La Misère*

de la philosophie, réponse à la philosophie de la misère de M. Proudhon (Paris, 1847; new ed., 1892; English ed., *The Poverty of Philosophy*, London, 1900); *Lohnarbeit und Kapital*, pamphlet, written 1848 (new ed., Berlin, 1891); English ed., *Wage, Labour and Capital* (London, 1900); *Die Klassenkämpfe in Frankreich, 1848 to 1850* (Berlin, 1895); *Der Achtzehnte Brumaire des Louis Bonaparte* (New York, 1852; 3rd ed., Hamburg, 1889; Eng. ed., New York, 1889); *Enthüllungen über den Kölner Kommunistenprozess* (Basel, 1852; new ed., Zürich-Berlin, 1885); “European Revolutions and Counter-Revolutions” (reprints from the *New York Tribune*, 1851-1852; London, 1897); “The Eastern Question” (reprints from the *New York Tribune*, 1853-1856; London, 1898); *Zur Kritik der politischen Ökonomie* (Berlin, 1859; new ed., Stuttgart, 1897); *Herr Vogt* (London, 1860); *Inaugural Address of the International Working Men’s Association* (London, 1864); *Value, Price and Profit* (written 1865, published London, 1898); *Das Kapital, Kritik der politischen Ökonomie* (3 vols., Hamburg, 1867, 1885 and 1895; Eng. ed. of 1st vol., 1886); *The Civil War in France, 1871* (London, 1871; new ed., 1894); *L’Alliance de la démocratie socialiste* (London, 1873); articles printed or reprinted in *Rheinische Zeitung* (1842-1843), *Deutsch-französische Jahrbücher* (Paris, 1844), *Das westphälische Dampfboot* (Bielefeld und Paderborn, 1845-1848), *Der Gesellschaftsspiegel* (Elberfeld, 1846), *Deutsche brüsseler Zeitung* (Brussels, 1847), *Neue rheinische Zeitung* (daily, Cologne, 1848-1849; monthly, Hamburg, 1850), *The People* (London, 1852-1858), *The New York Tribune* (New York, 1853-1860), *The Free Press* (Sheffield and London, 1856-1857), *Das Volk* (London, 1859), *Der Vorbote* (Geneva, 1866-1875), *Der Volkstaat* (Leipzig, 1869-1876), *Die Neue Zeit* (Stuttgart, 1883, sqq.); *Sozialistische Monatshefte* (Berlin, 1895, sqq.). (2) Of Friedrich Engels alone: *Die Lage der arbeitenden Klassen in England* (Leipzig, 1845; new ed., Stuttgart, 1892; Eng. ed., London, 1892); *Zur Wohnungsfrage* (Leipzig, 1873-1874; new ed., Zürich-Berlin, 1887); *Herrn Eugen Dührings Umwälzung der Wissenschaft* (Leipzig, 1877; 3rd ed., Stuttgart, 1894). Three chapters of the first-named are published in English under the title *Socialism, Utopian and Scientific* (London, 1892). *Der Ursprung des Eigentums, der Familie und des Staates* (Zürich and Stuttgart, 1885 and 1892); *Ludwig Feuerbach und der Ausgang der klassischen deutschen Philosophie* (Stuttgart, 1886). Introductions to most of the posthumous works of K. Marx and articles in the same periodicals as Marx. (3) Of Karl Marx and Friedrich Engels together: *Die heilige Familie oder Kritik der kritischen Kritik* (Frankfurt, 1845); *Manifest der kommunistischen Partei* (London, 1848; Eng. ed., 1848 and 1888). (4) With regard to Marx generally, his theory and his school, see J. Stammhammer, *Bibliographie des Sozialismus und Kommunismus* (Jena, 1893); and Th. G. Masaryk, *Die philosophischen und soziologischen Grundlagen des Marxismus* (Vienna, 1899). Much biographical and bibliographical information on Marx and Engels is to be found in Dr Franz Mehring, *Geschichte der deutschen Sozialdemokratie* (Stuttgart, 1897-1898), and in the collection, edited also by Dr Fr. Mehring, *Aus dem literarischen Nachlass von Karl Marx, Friedrich Engels und Ferdinand Lassalle* (Stuttgart, 1902). Of the criticisms of Marx’s economics, one of the most comprehensive is E. von Boehm-Bawerk’s *Karl Marx and the Close of his System* (London, 1898).

Marx's historic theory is, apart from Masaryk, very exhaustively analysed by R. Stammler in *Wirtschaft und Recht* (Leipzig, 1896).

ENGELS' SPEECH AT THE GRAVE OF KARL MARX by Friedrich Engels

*Delivered at the burial service for Karl Marx, Highgate Cemetery, London.
March 17, 1883*

On the 14th of March, at a quarter to three in the afternoon, the greatest living thinker ceased to think. He had been left alone for scarcely two minutes, and when we came back we found him in his armchair, peacefully gone to sleep — but for ever.

An immeasurable loss has been sustained both by the militant proletariat of Europe and America, and by historical science, in the death of this man. The gap that has been left by the departure of this mighty spirit will soon enough make itself felt.

Just as Darwin discovered the law of development or organic nature, so Marx discovered the law of development of human history: the simple fact, hitherto concealed by an overgrowth of ideology, that mankind must first of all eat, drink, have shelter and clothing, before it can pursue politics, science, art, religion, etc.; that therefore the production of the immediate material means, and consequently the degree of economic development attained by a given people or during a given epoch, form the foundation upon which the state institutions, the legal conceptions, art, and even the ideas on religion, of the people concerned have been evolved, and in the light of which they must, therefore, be explained, instead of vice versa, as had hitherto been the case.

But that is not all. Marx also discovered the special law of motion governing the present-day capitalist mode of production, and the bourgeois society that this mode of production has created. The discovery of surplus value suddenly threw light on the problem, in trying to solve which all previous investigations, of both bourgeois economists and socialist critics, had been groping in the dark.

Two such discoveries would be enough for one lifetime. Happy the man to whom it is granted to make even one such discovery. But in every single field which Marx investigated — and he investigated very many fields,

none of them superficially — in every field, even in that of mathematics, he made independent discoveries.

Such was the man of science. But this was not even half the man. Science was for Marx a historically dynamic, revolutionary force. However great the joy with which he welcomed a new discovery in some theoretical science whose practical application perhaps it was as yet quite impossible to envisage, he experienced quite another kind of joy when the discovery involved immediate revolutionary changes in industry, and in historical development in general. For example, he followed closely the development of the discoveries made in the field of electricity and recently those of Marcel Deprez.

For Marx was before all else a revolutionist. His real mission in life was to contribute, in one way or another, to the overthrow of capitalist society and of the state institutions which it had brought into being, to contribute to the liberation of the modern proletariat, which he was the first to make conscious of its own position and its needs, conscious of the conditions of its emancipation. Fighting was his element. And he fought with a passion, a tenacity and a success such as few could rival. His work on the first *Rheinische Zeitung* (1842), the *Paris Vorwärts* (1844), the *Deutsche Brüsseler Zeitung* (1847), the *Neue Rheinische Zeitung* (1848-49), the *New York Tribune* (1852-61), and, in addition to these, a host of militant pamphlets, work in organisations in Paris, Brussels and London, and finally, crowning all, the formation of the great International Working Men's Association — this was indeed an achievement of which its founder might well have been proud even if he had done nothing else.

And, consequently, Marx was the best hated and most calumniated man of his time. Governments, both absolutist and republican, deported him from their territories. Bourgeois, whether conservative or ultra-democratic, vied with one another in heaping slanders upon him. All this he brushed aside as though it were a cobweb, ignoring it, answering only when extreme necessity compelled him. And he died beloved, revered and mourned by millions of revolutionary fellow workers — from the mines of Siberia to California, in all parts of Europe and America — and I make bold to say that, though he may have had many opponents, he had hardly one personal enemy.

His name will endure through the ages, and so also will his work.

The Delphi Classics Catalogue

We are proud to present a listing of our complete catalogue of English titles, with [new titles](#) being added every month. Buying direct from our [website](#) means you can make great savings and take advantage of our instant Updates service. You can even purchase an entire series ([Super Set](#)) at a special discounted price.

Only from our website can readers purchase the special [Parts Edition](#) of our Complete Works titles. When you buy a Parts Edition, you will receive a folder of your chosen author's works, with each novel, play, poetry collection, non-fiction book and more divided into its own special volume. This allows you to read individual novels etc. and to know precisely where you are in an eBook. For more information, please visit our *Parts Edition* [page](#).

Series Contents

Series One

Anton Chekhov

Charles Dickens

D.H. Lawrence

Dickensiana Volume I

Edgar Allan Poe

Elizabeth Gaskell

Fyodor Dostoyevsky

George Eliot

H. G. Wells

Henry James

Ivan Turgenev

Jack London

James Joyce

Jane Austen

Joseph Conrad

Leo Tolstoy

Louisa May Alcott

Mark Twain

Oscar Wilde

Robert Louis Stevenson

Sir Arthur Conan Doyle

Sir Walter Scott

The Brontës

Thomas Hardy

Virginia Woolf
Wilkie Collins
William Makepeace Thackeray

Series Two

Alexander Pushkin
Alexandre Dumas (English)
Andrew Lang
Anthony Trollope
Bram Stoker
Christopher Marlowe
Daniel Defoe
Edith Wharton
F. Scott Fitzgerald
G. K. Chesterton
Gustave Flaubert (English)
H. Rider Haggard
Herman Melville
Honoré de Balzac (English)
J. W. von Goethe (English)
Jules Verne
L. Frank Baum
Lewis Carroll
Marcel Proust (English)
Nathaniel Hawthorne
Nikolai Gogol
O. Henry
Rudyard Kipling
Tobias Smollett

Victor Hugo
William Shakespeare

Series Three

Ambrose Bierce
Ann Radcliffe
Ben Jonson
Charles Lever
Émile Zola
Ford Madox Ford
Geoffrey Chaucer
George Gissing
George Orwell
Guy de Maupassant
H. P. Lovecraft
Henrik Ibsen
Henry David Thoreau
Henry Fielding
J. M. Barrie
James Fenimore Cooper
John Buchan
John Galsworthy
Jonathan Swift
Kate Chopin
Katherine Mansfield
L. M. Montgomery
Laurence Sterne
Mary Shelley

Sheridan Le Fanu
Washington Irving

Series Four

Arnold Bennett
Arthur Machen
Beatrix Potter
Bret Harte
Captain Frederick Marryat
Charles Kingsley
Charles Reade
G. A. Henty
Edgar Rice Burroughs
Edgar Wallace
E. M. Forster
E. Nesbit
George Meredith
Harriet Beecher Stowe
Jerome K. Jerome
John Ruskin
Maria Edgeworth
M. E. Braddon
Miguel de Cervantes
M. R. James
R. M. Ballantyne
Robert E. Howard
Samuel Johnson
Stendhal

Stephen Crane
Zane Grey

Series Five

Algernon Blackwood
Anatole France
Beaumont and Fletcher
Charles Darwin
Edward Bulwer-Lytton
Edward Gibbon
E. F. Benson
Frances Hodgson Burnett
Friedrich Nietzsche
George Bernard Shaw
George MacDonald
Hilaire Belloc
John Bunyan
John Webster
Margaret Oliphant
Maxim Gorky
Oliver Goldsmith
Radclyffe Hall
Robert W. Chambers
Samuel Butler
Samuel Richardson
Sir Thomas Malory
Thomas Carlyle
William Harrison Ainsworth

William Dean Howells

William Morris

Series Six

Anthony Hope

Aphra Behn

Arthur Morrison

Baroness Emma Orczy

Captain Mayne Reid

Charlotte M. Yonge

Charlotte Perkins Gilman

E. W. Hornung

Ellen Wood

Frances Burney

Frank Norris

Frank R. Stockton

Hall Caine

Horace Walpole

One Thousand and One Nights

R. Austin Freeman

Rafael Sabatini

Saki

Samuel Pepys

Sir Issac Newton

Stanley J. Weyman

Thomas De Quincey

Thomas Middleton

Voltaire

William Hazlitt
William Hope Hodgson

Series Seven

Adam Smith
Benjamin Disraeli
Confucius
David Hume
E. M. Delafield
E. Phillips Oppenheim
Edmund Burke
Ernest Hemingway
Frances Trollope
Galileo Galilei
Guy Boothby
Hans Christian Andersen
Ian Fleming
Immanuel Kant
Karl Marx
Kenneth Grahame
Lytton Strachey
Mary Wollstonecraft
Michel de Montaigne
René Descartes
Richard Marsh
Sax Rohmer
Sir Richard Burton
Talbot Mundy

Thomas Babington Macaulay
W. W. Jacobs

Series Eight

Anna Katharine Green
Arthur Schopenhauer
The Brothers Grimm
C. S. Lewis
Charles and Mary Lamb
Elizabeth von Arnim
Ernest Bramah
Francis Bacon
Gilbert and Sullivan
Grant Allen
Henryk Sienkiewicz
Hugh Walpole
Jean-Jacques Rousseau
John Locke
John Muir
Joseph Addison
Lafcadio Hearn
Lord Dunsany
Marie Corelli
Niccolò Machiavelli
Ouida
Richard Brinsley Sheridan
Sigmund Freud
Theodore Dreiser

Walter Pater
W. Somerset Maugham
